Although the fruiting season is the time when the grower reaps the harvest of his labours, the amount of his returns (weather permitting), depends much upon the way he has treated his plantations. It is not my intention, however, to now dwell upon the general management of strawberries, but rather to make some seasonable remarks upon it.

With the lengthening of days, and increase of the sun's power, the strawberry, after having had a season of rest, commences to make fresh growth, and at that time the soil should be surface hoed, and the plants be given a thorough watering with diluted farmyard liquid. To recommend this so early in the year, and at a time when the land is usually quite moist, may appear a wild notion to the inexperienced cultivator, yet it is quite practicable, and if this is doubted, let the sceptic practise it upon a portion of his plants, leave the remainder, and mark results, and I shall be surprised if he does not readily find a marked difference between the two sets, and this to the advantage of those treated with liquid manure.

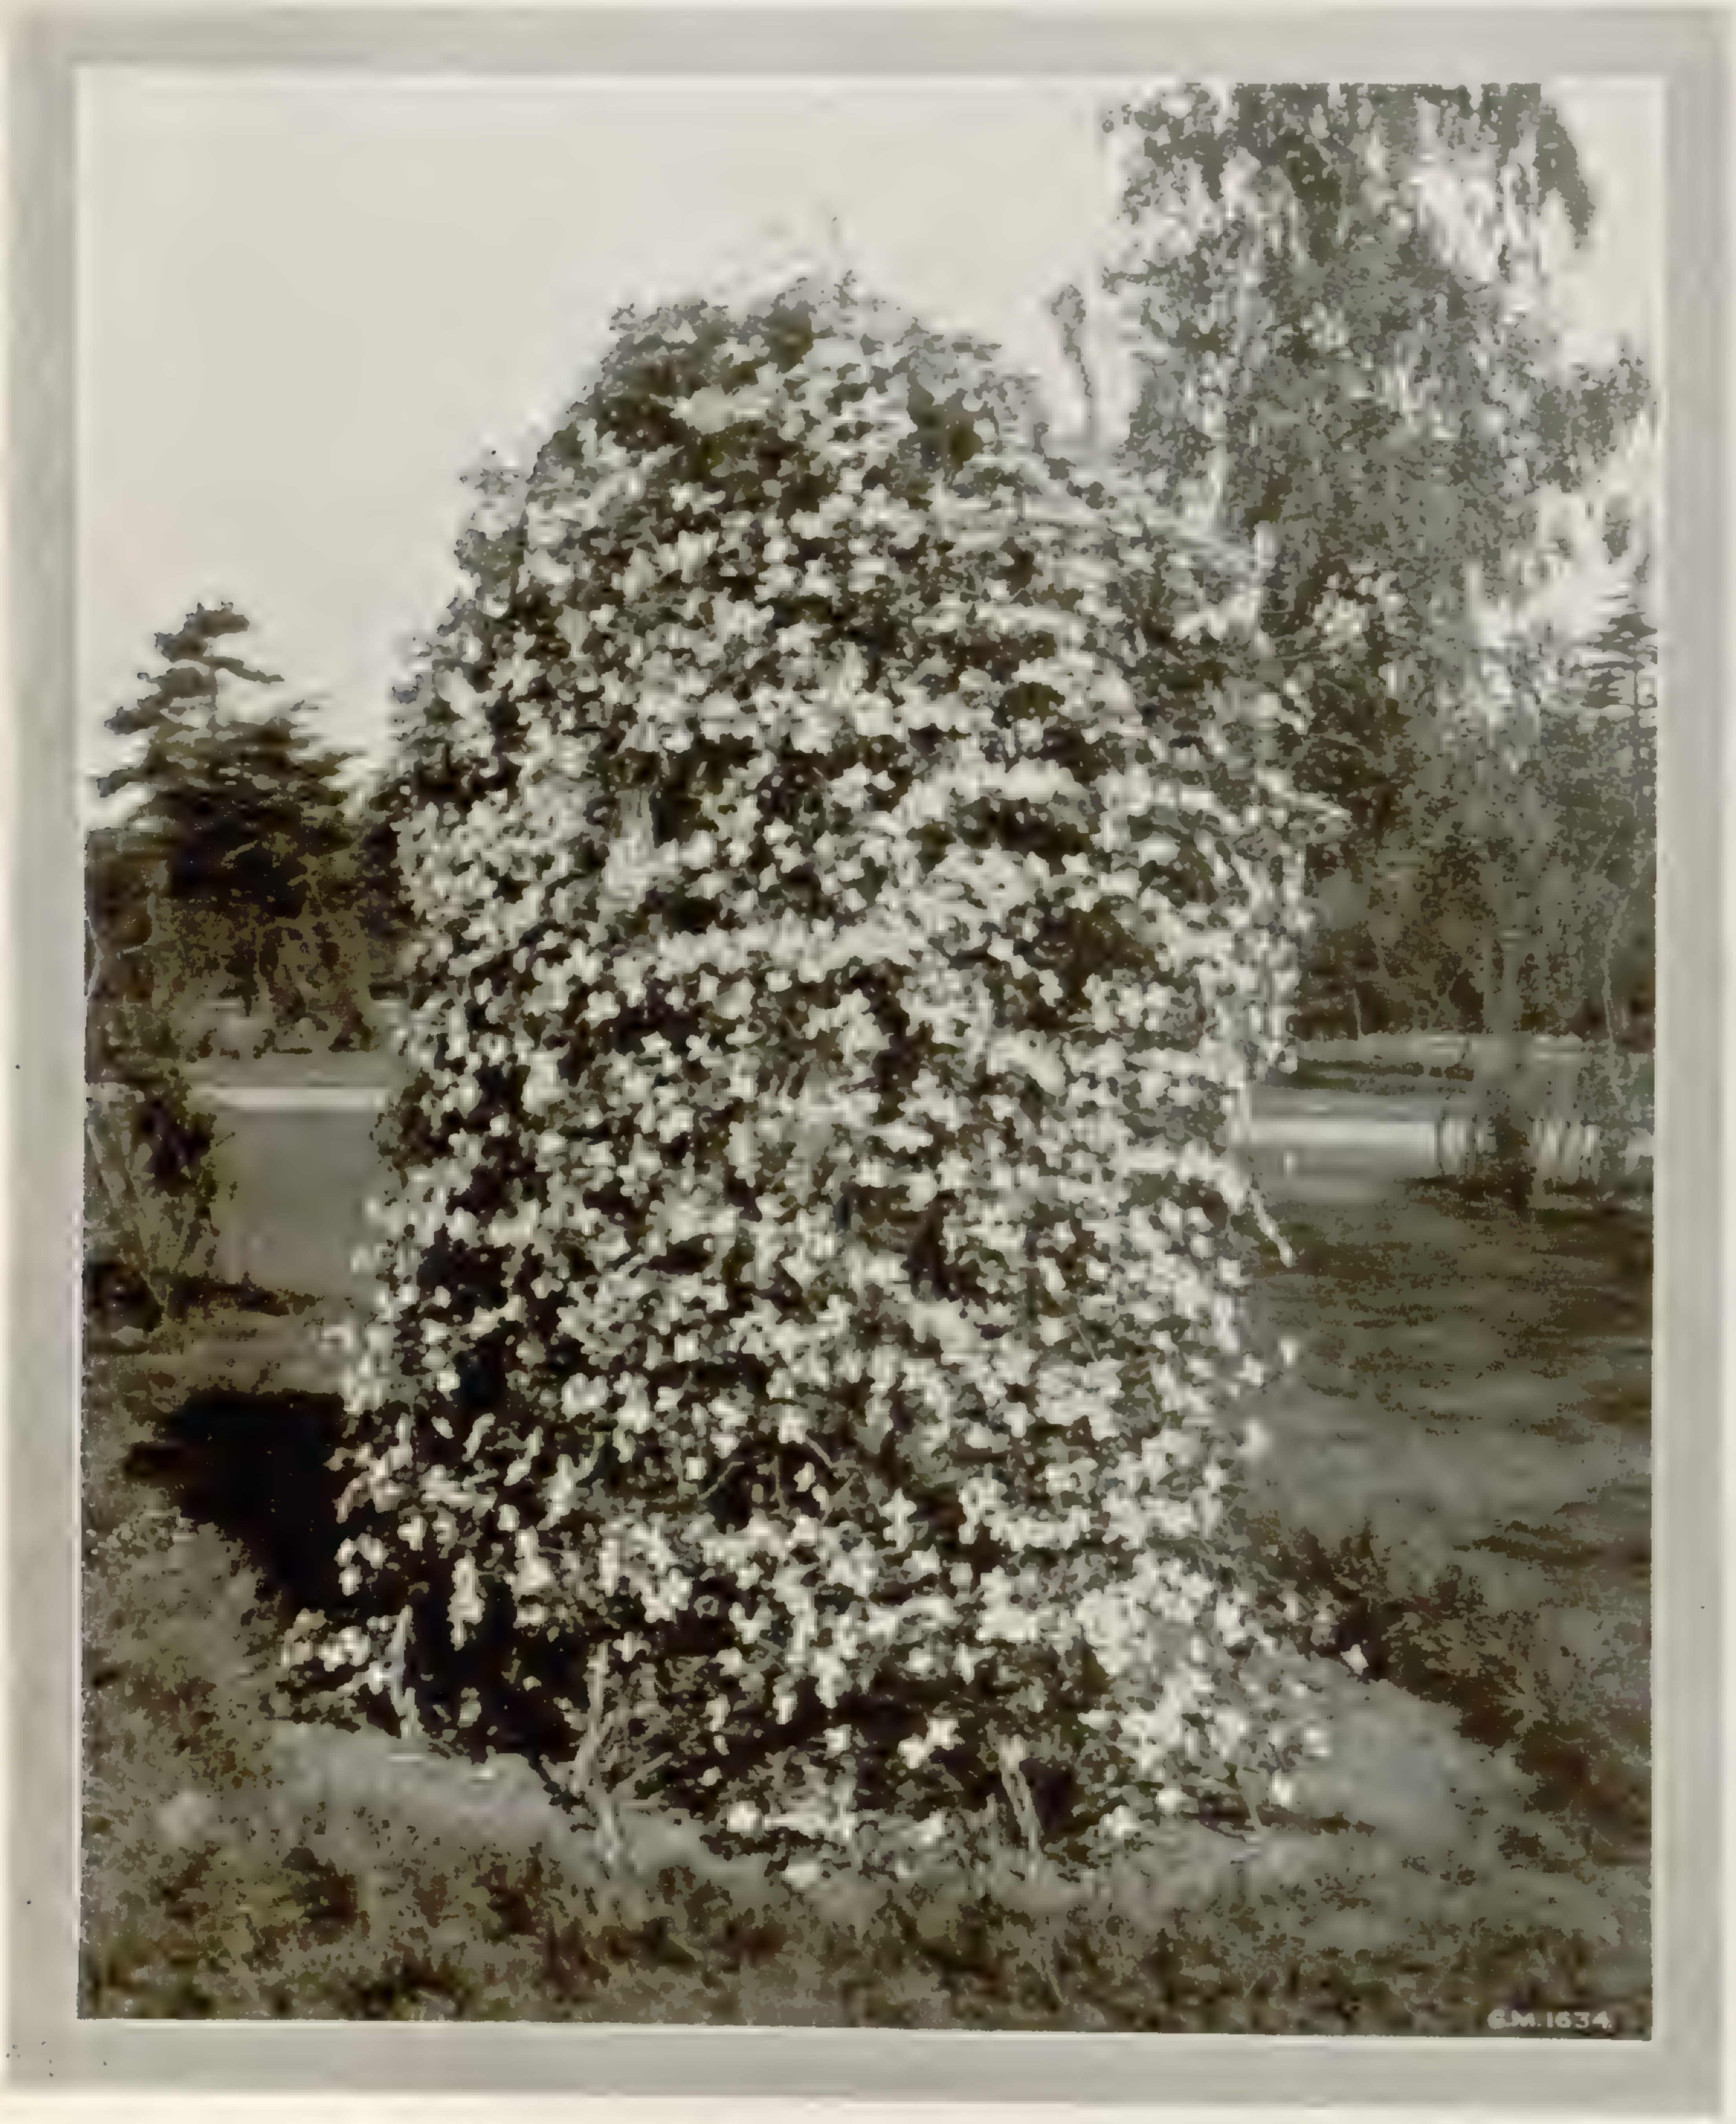
Other similar waterings should be given immediately before the fruit blossoms expand, and again when the fruit commences to swell, while at no time should the plants be allowed to suffer from want of water. If liquid manure of this description is not available, top-dressings of a suitable soluble artificial compound will answer the purpose: nitrate of soda also suits well, and particularly so in the case of light soils, as it is both a valuable quickly-acting stimulant, and a good assistant in keeping the soil moist. Previous to the plants coming into blossom, and at a time when the soil is perfectly moist, with a view to keeping the fruit clean and the land from becoming dry, a mulching of straw should be carefully applied. Preceding this a good dressing of soot should be given, which, apart from affording valuable manurial benefits, acts usefully as a deterrent to slugs.

If the site of the plantation is subject to spring frosts, as is the case here, some efficient means for protecting the blossoms should be adopted, otherwise the best part of the crop will probably be lost. Strips of tiffany answer well for the purpose, and they can be readily placed over and removed from the rows, but even these, is allowed to remain in contact with the flowers, cannot be depended upon as perfectly effectual. This defect can, however, be obviated by placing wooden splints supported by short forked sticks over the rows, and resting the strips of tiffany upon them, thus keeping them clear of the blossoms. It is necessary to take these precautions against the effects of frost as soon as the flower buds become prominent.

Fruit grown for dessert, if wanted large in size, must be well thinned as soon as the best berries can be distinguished, but the extent to which this should be carried out must depend upon the varieties grown, the vigour of the plants, and the way they are supported with manures. Where severe thinning is done, and the most promising fruits only left, the length of time any variety can yield a supply of fruit is, of course, considerably curtailed, and this, especially to growers of a comparatively few varieties only, may incur inconvenience and disappointment, which are not felt by those who grow good collections of early, midseason, and late varieties. In the case of fruit grown for the kitchen mere size is of little moment, and, consequently, thinning is unnecessary.

The fact that a considerable portion of the strawberry crop rests on the ground, unless adequate measures are taken to prevent it, often leads to much loss from the effect of rain, slugs, millipedes, etc., but these evils can, to a great extent, be counteracted by carefully supporting the fruits. This, of course, entails much work, but it well repays those who carry it into practice. Mice also are sometimes very destructive, and the best way of dealing with these is to rid the quarters of them with figure 4 or other traps, before the fruiting season commences. Birds, again, unless efficient means are taken to prevent them, destroy much fruit. A good way of frustrating their efforts is to fix stakes, standing about four feet out of the ground, round, and through the plantations, run lines of strong wire from stake to stake, and upon the framework thus prepared securely fix herring netting.

T. Coomber.



A SPLENDIDLY DEVELOPED SPECIMEN OF CLEMATIS MONTANA RUBENS AT KEW.

A handsome Chinese variety of the Mountain Clematis with rose-red flowers.

CLEMATIS MONTANA RUBENS.

Many hundreds of times have the praises of Clematis montana been sung in the pages of the Gardeners' Magazine, and the merits of the rosy-red counterpart of this beautiful old free-growing climber have also been frequently put before our readers since its introduction from China a few years ago. C. montana rubens grows and flowers as freely as the white Himalayan type, and is a fine companion to it, while under any and every condition that is suitable for the one both will thrive. C. montana is usually planted for the purpose of covering a porch, a house front, a verandah, a balcony, a fence, an archway, or an old tree, and C. montana rubens is of equal value for such purposes. At Kew, clematises are grown to form rounded pyramids, or wigwams, one or more plants being trained round a group of stout poles. In this way they do not fully show off their peculiar grace, but they produce strikingly novel effects, and the masses of floral colour produced by them can be seen from a long distance. Clematis montana rubens has been pressed into service in this way, and last season it was a rare sight so grown. The accompanying illustration of the Kew specimen, from a photo by Mr. C. P. Raffil, may perhaps lead those in charge of large public or private gardens to adopt a similar method of culture for this and other clematises, not, of course, forgetting the other methods.

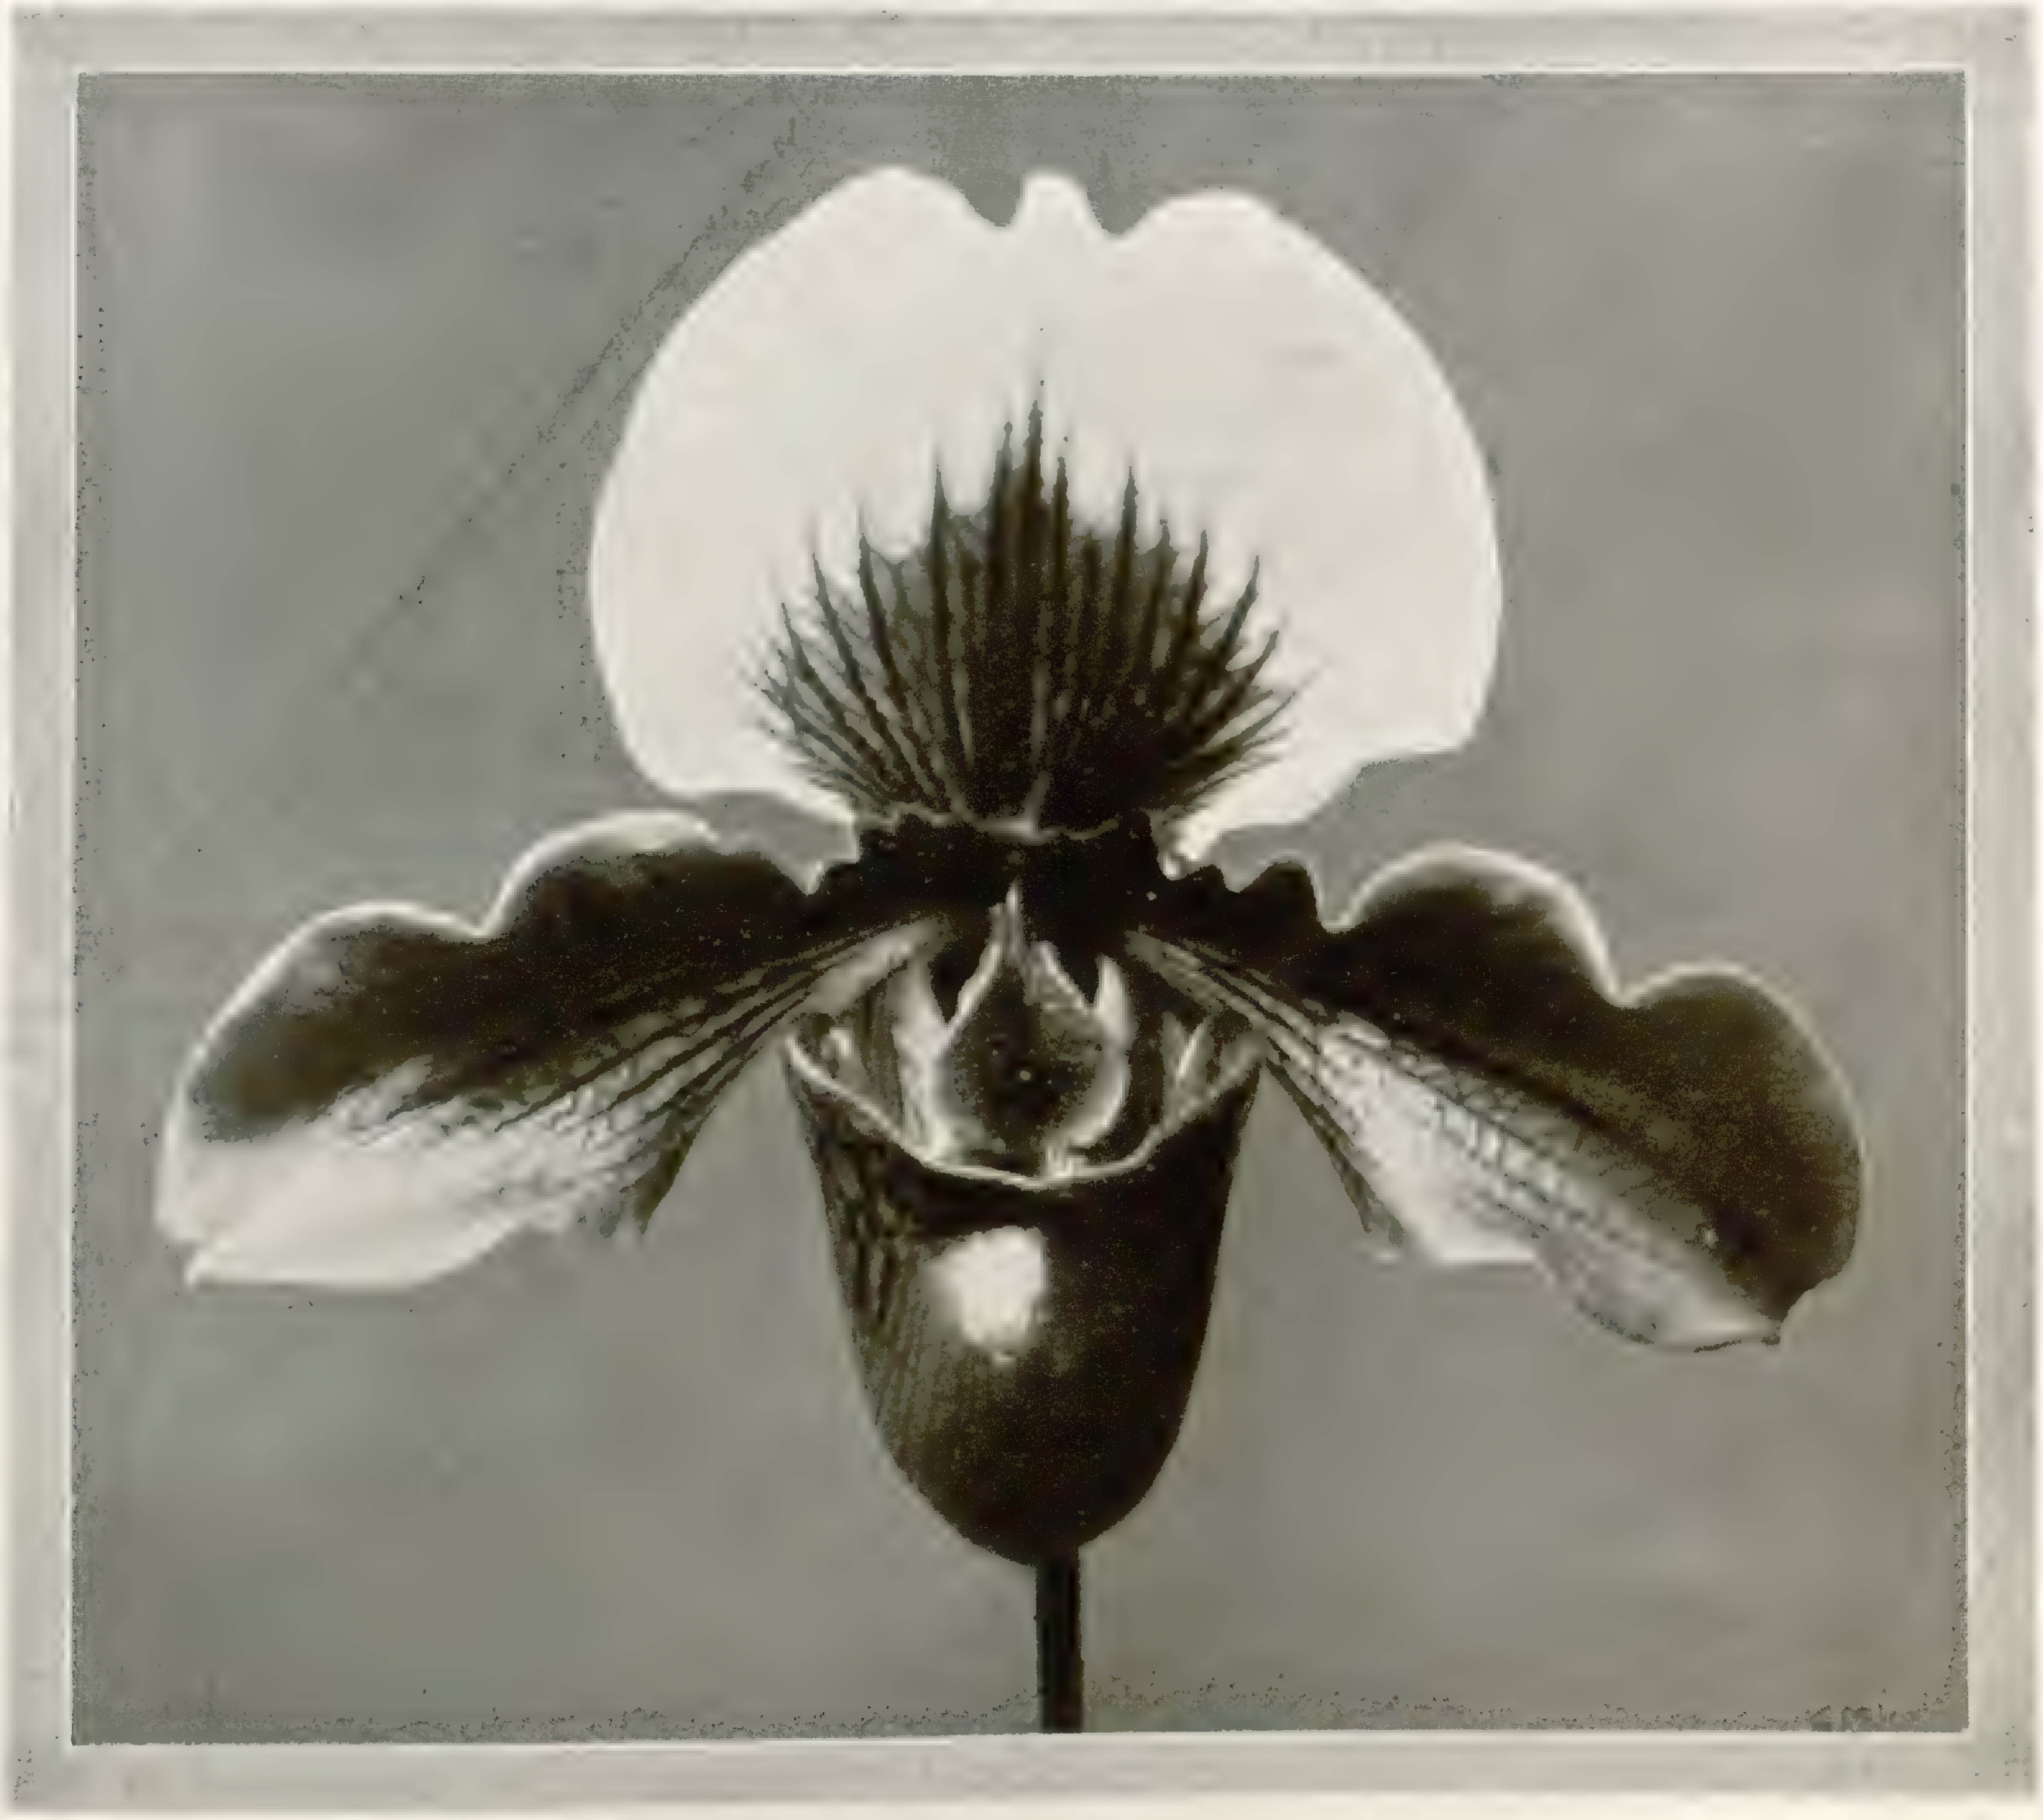
NEW PLANTS, ETC.

BRASSO-CATTLEYA SENATEUR DE BAST.

A very handsome and beautiful hybrid, derived from Brasso-cattleya Digbyano-Mossiæ and B.-c. Mrs. J. Leeman. The flower is of fine size and proportions; the sepals and petals are rich deep purplish-rose colour, and the broad, rounded, and elegantly fringed lip, rosy-purple, freely veined, and shaded with golden-yellow. F.C.C., R.H.S., February 14. Messrs. Theodore Pauwels and Co., Meirlebeke, Ghent.

CYMBIDIUM LAWRENCEANUM.

A new hybrid, bearing its (in this case) single flower on a long stem. The parents are C. insigne and C. Lowianum. The flower has a considerable resemblance to the last-named, but the growth of the plant shows the influence of C. insigne. There is a large deep red blotch on the creamy lip, and the sepals and petals are also cream coloured, shaded with rose. A.M., R.H.S., February 14. Messrs. Theodore Pauwels and Co., Meirlebeke, Ghent.



CYPRIPEDIUM AUREUM LAEKENENSE.
Flowers yellow-green and white. A.M., R.H.S., February 14. Mr. E. V. Low.

CYPRIPEDIUM CAROLA.

An effective and well-proportioned flower. The broad, rounded dorsal sepal has a large white apical area, flushed heavily with rose-purple below, and with a green base. Both in the petals and the lip, the bright glistening yellow-green colour is shaded with deep brown. The parents of C. Carola are C. Fioumsonianum magnificum and C. Euryades splendens. A.M., R.H.S., February 14. Messrs. Hassall and Co., Southgate.

CYPRIPEDIUM AUREUM LAEKENENSE.

A very attractive orchid, obtained by crossing C. Sallieri hyeanum with C. Spicerianum. The general colour is yellowish-green, but there is a broad white band around the dorsal sepal, and some light brown shading on the lip. A.M., R.H.S., February 14. Mr. E. V. Low, Haywards Heath.

CARNATION CORONATION.

This perpetual-flowering carnation has flowers of rich rose-pink hue, and of large size; the calyx is entire, and the stems long and stiff. The variety is fragrant, but not heavily scented. A.M., R.H.S., February 14. Mr. B. E. Bell, Castel Nursery, Guernsey.

ROSA PERNETIANA—III.

The new break in roses derived from Rosa lutea, and originated by M. Pernet Ducher, has been augmented by a few more sent out by other raisers. Messrs. William Paul and Son's Juliet, the premier of the race raised in the British Isles, has received notice in the first of these articles, so we may pass on. With the exception of Gottfried Keller and Entente Cordiale, we possess little knowledge of the varieties which follow, but inasmuch as they are classed as Pernetiana, they claim a passing reference.

Gottfried Keller (Dr. Muller, 1902).—In point of time Gottfried Keller followed closely on the heels of Soleil d'Or. It is a rose which shows closer affinity to the type than any other of the series. We can see it in the wood, prickles, foliage, bloom, and habit. The wood is dark red, inclining to brown, prickles pale buff, scattered, the habit long and straggling. The flowers are almost single, possessing the brilliant yellow of R. lutea slightly suffused with pink, and when staged in a bunch are very attractive. But one has to cut over a great many plants to obtain sufficient flowers to make a bunch. From this it will be perceived that it is not a good garden rose. One has tried various methods to make it free flowering, but hitherto unsuccessfully. Cut hard or left long and pegged down makes no difference, it just flowers here and there at the tips, and has many blind shoots. Nevertheless the colour is very attractive, and it is perpetual and blooms late in autumn.

Entente Cordiale (Guillot, 1908).—Apparently we have here a good variety of the race. The flowers are large, petals loosely put together, semi-double, long buds. Colour, nasturtium red or golden yellow ground, with bright yellow stamens, edges of petals salmon-carmine. Growth dwarf and compact. As seen at exhibitions it is distinctly attractive. There is another rose of the same name, a hybrid tea, with which it must not be confused.

Soleil d'Angers (Ch. Dietricht, 1909).—This rose is stated to be a sport, and is described by the introducer as "a red Soleil d'Or." Colour vermilion-red, base of petals deep yellow.

Louis Barbier (Barbier, 1909). A dwarf pillar decorative variety. Flowers semi-double, produced in clusters, free-flowering, perpetual. Colour, bright coppery rose changing to pink or purple-red. Outside of petals coppery yellow.

Madame Ruau (Gravereaux, 1909).—Long bud opening globular. Colour carmine-pink shaded yellow. Outside of petals tinted yellow. Free flowering through summer and autumn.

JOSEPH H. PEMBERTON.

PLANT HOUSES.

One of the great businesses of modern times is the production of choice exotic and other plants in ever-increasing numbers for brightening the surroundings of home life and social functions of all kinds. The structures now erected for these are ideal homes for the entire process of plant manufacture. Since horticulturists discovered that the health of their plants increased with more light and air, the evolution of plant houses may be said to have made amazing strides.

Perhaps the greatest impetus to improved conditions was the removal of duty from glass, which formerly was a very heavy item, and this, to some extent, explains why all old glass structures had such heavy beams, thick sash bars, and innumerable small panes of glass. The ventilating, too, was very inferior, large loose sashes being let down at the top of the house by pulleys and cord with a heavy weight attached. Practical men may realise what ventilation of this kind meant during stormy periods, and doubtless are thankful for changed conditions. Front ventilation, too, was usually of the same clumsy character, and to crown all, the heating usually consisted of a brick flue carried round the house; it consumed a good deal of fuel, and frequently smoke and sulphur fumes broke through, doing serious harm to the occupants.

Of course, the use of large panes of glass and smaller quantities of wood were not the only conditions that brought about the present healthy surroundings for the occupants of glass structures, for to these must be added the improved heating arrangements, whereby the temperature of the interior may be maintained in accordance with the class of plants housed. Perhaps hot water has helped the gardener to produce a more natural and healthy condition for his plants than the increased size in the panes of glass now used. It may be very truly said that the present-day arrangement of heating glass structures by hot water pipes is well understood by the majority of growers, and in modern systems of heating we very rarely find the mains in the narrow channels in which they were fixed a few years back, but in trenches sufficiently wide to allow for repairs being attended to without inconveniencing the workman or causing excavations of an unnecessary character.

Work well done in the first instance with respect to heating will, in the end, mean the saving of much time and annoyance; and since the system of heating is mostly so arranged that neither space nor heat is wasted, both stoking and fuel consumption are more economically managed. Many of us can remember the time when the best of gardens possessed almost as many boilers as houses.

The boilers of to-day, and the stoke-holes in which they are set, are as important as the structures for the plants. Many of the large sectional boilers are also highly economical as regards the consumption of fuel. Very frequently, too, they are set in pairs, and so arranged that should any mishap occur to one, the work of heating may be easily transferred to the other. A good deal of importance is attached to such an arrangement, especially now that a large area of glass is heated from one centre, and the loss would be a heavy one should mishap occur during severe weather without any means of applying warmth.

Plant houses, both for growing plants and displaying their beauty, are now mainly wooden structures. At one time, when lightness and elegance seemed to be gaining ground, iron structures were, by some, thought superior to wood. In practice, however, serious drawbacks were soon in evidence; if the painting was neglected, rust soon made serious headway, and the drip from rusty bars soon injured choice subjects beneath. Iron houses were also more expensive than wooden ones, and also more expensive to heat, as the warmth passes through iron much quicker than wood. Of course, plant houses cannot be so strongly built, or elegantly made, unless iron is used in some form or other, and present-day builders make good use of brackets and spandrils, with tension rods and light principals for trussing the roof. Nearly all modern builders may be said to aim at strength, with a light and elegant appearance. Thick rafters can safely be dispensed with when the accessories previously named are scientifically employed. The amount of paint required to cover all parts of modern houses, and putty, too, for glazing them, must have greatly diminished, and this improvement must mean less annual expense, both as regards labour and material.

In glass houses the varying temperatures, the large amount of atmospheric moisture, and other conditions, all tend to decay the wood. Houses intended as stoves, ferneries, and for orchids from the more moist climes, cannot be too lightly built; of course, strength must be combined, but the smaller the amount of woodwork used the more quickly it will dry. In glasshouses it is always the thickest and stoutest wood that decays first, as anyone may soon find out by examining a glass structure. The glass used must of necessity be the best, for on the quality of the glass depends the freedom from such blemishes as scalding or burning of the foliage. The best sheet glass should be obtained, and for the roof and exposed ends should be 21oz. The best system of glazing is to bed the glass firmly on a rather thin layer of the best putty, and, providing this part is well done and the panes are cut to fit neatly between the bars, sprigged, and afterwards painted, water will not get in from the outside of the house. Sometimes the glass employed is cut with a curved instead of a square edge, to draw the water from the bars and conduct it down the centre of the pane. Personally, I much preter the specially-grooved bars for drip prevention to curved glass, which quickly becomes very dirty.

For carrying the stages in any house where much moisture and heat are required, iron supports are preferable to any other, and slate slabs on which to place such moisture-holding material as the district provides. Orchid houses are sometimes built of teak, and the stages are also composed of this expensive wood. There are other factors that influence the occupants, such as the careful arrangements for giving air, a requisite amount of piping, an adequate surface for moisture-holding material, and a simple but effective means of giving the necessary shade when required; these few things may be said to embody the secret of successful plant culture. The width of staging, the distance it is arranged from the ground, its proximity to the pipes, and its position as regards ventilation, must all be considered.

The sizes of houses are, or should be mainly regulated by the requirements of the owner. Present-day owners of private gardens are mostly content with a small and free-flowering type of plant, or something that may be grown solely for its flowers in a cut state; and since size with elegance can be had in palms, bamboos, and various grasses for associating with smaller flowering plants and cut flowers, the best of effects can be secured from the artist's standpoint. Span-roofed houses, with their ends north and south, are preferable to others for growing shapely plants; if small plants only are required houses 12ft. wide will meet the requirements, but if larger plants must also have provision made for them, then the houses may vary from 18ft. to 24ft., or even 30ft. wide, which width allows of a good centre stage, with side stages and walk around the centre stage for viewing and giving attention to the plants. The narrow house will, of course, only have a centre path, with the side stages about 4ft. 6in. wide on either side of it. The stages should not be fixed too high, the usual level for the stage on the sides being the same as the height of the wall, which may be from 2ft. 6in. to 3ft. 6in. high; if the former, soil would have to be taken from the house to allow for the stage standing at least 3ft. from the path. For allowing air to enter the house during the coldest period of the year, bottom ventilators 2ft. by 10in. are best fixed in the brickwork at intervals of 6ft., opposite the hot water pipes. The narrower houses will only require pipes on both sides, but larger structures, for tropical plants, will also require heating from the centre bed. Greenhouse plants will be happy enough providing a temperature of 40 deg. can be kept up during the most severe weather. To prevent overheating the pipes, and to keep up warmth, a span house, 12ft. wide, should have three rows of pipes on either side; 18ft. wide, four rows, and wider houses an additional two rows round the centre stage. The warmer structures are best arranged near to the boiler and mains, and those for cooler occupants further away.

Lean-to structures with the wall facing south, or slightly south-east, are, perhaps, more economical as regards heating, because the coldest winds are kept off and the glass is in the best position for receiving all the sunlight possible. The stages in lean-to houses are usually fixed in steps for a portion of their distance, finishing off with a wider flat portion. Ventilation in a lean-to may be continuous both top and bottom, but for span-roofed houses, ventilation should be provided on both sides of the ridge and open alternately, as should also the front lights on either side of the house. Shading is an important item, and for such things as cool orchids the blinds are best so fixed that a current of air can pass between them and the glass.

For giving satisfaction all sills that are not of iron should be of the best well-seasoned pitch pine, as well as the plate to receive the sash-bars and to which the guttering will be fixed. If these sills are well seasoned, properly sloped, and kept well painted, they will never decay.

The walks in the houses may be made to suit the personal convenience of the owner. They vary from sifted gravel to stone slabs, cast-iron grating, and pitch-pine lattice; these latter last well, are easily taken up, are safe if nailed closely together, and always dry to walk over. It is sometimes necessary to provide for climbers to be trained up under the roof; in such cases light pillars are necessary, and they also assist to support the roof of very wide houses. Provision will also be necessary for arranging and placing suitable rooting mediums for stove or other climbers to be planted in. A better finish, too, is often given a house when the soil near the pipes can be covered with small ferns, mosses, tradescantias, panicums, etc.

F.

BULBS. A practical treatise on the cultivation of hardy, hothouse and greenhouse bulbous and tuberous-rooted plants is "BULBS AND THEIR CULTIVATION," by T. W. Sanders, price 2s. 6d. net, or by post 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

GREENHOUSE FLOWERS AT READING.

Two classes of greenhouse flowers, each easily raised from seed annually, have a popularity for winter decoration of the conservatory and the home that is not excelled by any others raised in similar fashion. These two are primulas and cyclamen. When "primulas" are referred to it goes without saying that the beautiful varieties of P. sinensis are understood, all other kinds of primulas having their own special, specific, or popular title under which they are recognised; but when the generic title in its plural form is used, we all know what is meant. Further, "Chinese primulas" means the same thing as "primulas," and yet there are other species than P. sinensis that hail from far Cathay. Everyone who has a warm greenhouse and a cold frame may grow primulas; they are easily managed, and consequently very popular.

ONE OF MESSRS. SUTTON AND SONS' LARGE PRIMULA HOUSES.

During the last quarter of a century a steady improvement has been going on in primula development, and every variation has been tested with a view to future developments. Especially has this kind of development been taken in hand by the Messrs. Sutton and Sons, Reading, who grow their own seeds of these choice flowers in their own establishment. The variation in leaf form has been worked out until now there are stocks of certain varieties that are identical in floral form and colour, and yet one may have fern-like leaves and the other plain leaves. Again, flowers may be identical in size, colour, and shape, and yet one stock will have pale green leaves and foot-stalks, and the other dark leaves and stems.

In cross-breeding, as well as in selection, the Reading firm have carried on a wonderful work, and hundreds of stocks of new cross-bred primulas are tested each year. So carefully have all the records been kept that the firm knows exactly what crosses to make to secure a new stock of any one of their catalogued varieties. Thus The Duchess, or any other beautiful variety, could be reproduced in two or three years if its parents were still available. With this knowledge before them the Messrs. Sutton can easily re-create or re-juvenate a variety, and it is in this way, and by rigid selection, that colour, habit, size, and constitution are kept up to high-water mark. Primulas are divided into four sections at Reading: the florists' type, the giant-flowered, the doubles, and the stellate group; and in all these there is a wide range of colour. One of the latest developments is an eyeless primula, that is, one in which the yellow or orange coloured eye has been eliminated, and a white central mark remains. Efforts are now being made in the case of coloured varieties to fill up the colourless or eyeless centre with the body colour of the flower, and if this can be done a quite new race of Chinese primulas will follow.

The Duchess stands pre-eminent among florists' primulas, and is at once beautiful and striking; the flowers are white with a zone of rosy-carmine round the yellow eye. Royal White, Crimson King, the dark blue Czar, the useful Reading Blue, and the good old White Pearl, make up a fine half-dozen, to which the fern-leaved Snowdrift, pure white, may well be added. The double varieties have pink, scarlet, blue, salmon, and white flowers, while Pink Beauty is flaked with salmon or pale pink, and there is now a double form of The Duchess that is particularly attractive.

The very beautiful "Giant" type is so highly bred that it seeds sparingly; the big substantial flowers with their splendid frilled and overlapping petals, owe their substance to skilful breeding and selection, and not in any degree to cultivation. Giant Royal White, Giant Salmon, Giant Pink, and Giant Crimson are all great favourites with keen lovers and cultivators of primulas, and deservedly so, as their production in first-rate form is evidence of no mean cultural ability. The grace of the stellate varieties is well known and appreciated, and few greenhouse plants are so decorative and generally useful. The Giant Stars are pretty, and their larger flowers appeal to some folks; but we confess to a love for the original form as represented by White Star, Ruby Star, Pink Star, and the Dark and Light Blue Star.

The Messrs. Sutton and Sons' grandiflora strain of Primula obconica is very fine, and just now the houses devoted to it, and the many devoted to primulas and cyclamen, provide a floral feast worth travelling a hundred miles to see. Pure white, pink, crimson, ruby, pale blue, and lilac varieties have been selected out, and are now offered true to colour; the white, light blue, and ruby varieties are exceptionally fine, and the latter has been given the varietal name of Fire King, one it richly deserves on account of its brilliance.

One of the great features in the development of cyclamen at the hands of the Messrs. Sutton is the delicious fragrance found in one of their strains, a fragrance that will, it is devoutly hoped, soon be extended to the ordinary and the giant flowered varieties. This year the fragrance is more marked than ever, and a further pleasure is added to that derived from the purity and richness of the colours, and the elegant forms of the multitude of flowers to be found in the cyclamen houses at Reading. As cut flowers cyclamens are many points ahead of the primulas, therefore a batch of well-grown plants of fine strain is worth a great deal to the gardener who has to provide choice flowers for vases in the home during the winter months, between the time of the chrysanthemum and the early bulbous flowers. The original Salmon Queen has passed away, and its place has been taken by Salmon Pink with large flowers of similar hue, and by Rich Salmon Pink, a brilliant variety that promises to develop still further along the warm salmon or orange-salmon colour line. White and crimson varieties of giant form, as well as mauve, purple, and cherry red selections are all of the highest merit; while White Butterfly is of surpassing elegance, and cannot be surpassed for its free growth and the enormous number of lovely blossoms a well-grown plant will produce.

Houses and pits well filled with cinerarias and herbaceous calceolarias, a queer looking plant that is supposed to be a hybrid between a primula and a cyclamen, frames full of carnations, and great breadths of sweet williams, are additional items of interest at the Messrs. Suttons' trial grounds. At the seed warehouses and the offices work is going full steam ahead to cope with the record crowd of seed orders pouring in from town and country, at home and abroad, and the extensive new seed potato store is a reminder of the fact that on the humble tuber that is so important a food product, the Reading firm has expended the same quality of skill and care that has done so much to make primulas and cyclamen what we find them to-day.

THE FUTURE OF THE SCOTTISH HORTICULTURAL ASSOCIATION.

At the February meeting of the Scottish Horticultural Association the newly-elected president, Mr. W. H. Massie, was inducted into his office, and delivered his presidential address. This was of much interest, as evidence that Mr. Massie fully appreciates the necessity for reform, and has very clear views as to the course that must be taken to place the association in a position to accomplish the work for which it was originally founded. He said,—

There is, I feel, one subject above all others which must be dear to every member of this association who has its real interests at heart, and from the circumstances in which we find ourselves, I have had no hesitation in selecting its future as my subject. Therefore, with your kind indulgence, I propose to lay before you my views on this important matter.

LOOKING BACK.

I will not unduly weary you with any lengthened remarks about the past history of the association. At the December meeting of last year you had, from one of your past presidents, Mr. Todd, an eloquent discourse on that, and in what I have to say regarding its past I will confine myself to what has a legitimate bearing on its future work. It is well to look back at times lest we forget. We learn from the past, the present is ours, and we can, to a large extent, influence the future.

I need not remind you that there have been conferences between this association and the Royal Caledonian Horticultural Society, of which many of us are also members, and of whose past work we feel justly proud, with a view to their amalgamation, and you must not for a moment imagine that any of the proposals which I am about to lay before you are intended to run counter to, or to thwart in any way, the union of the two organisations. Rather is it my intention in any suggestions I have to make to further and foster that union, which you will agree would be the means of strengthening the position of horticulture in the capital of our common country.

There is far too great concentration of interest by our wealthy classes in this country in the society which has its home in the great Metropolis, to the detriment of our own national societies, and if anything I can say or do as your president shall have the effect of giving a stimulus to greater interest in our leading Scottish horticultural societies, I shall feel that my election to this chair has not been in vain. There is no reason why they should not be Fellows of the English society, but do not, therefore, let them overlook their own people and institutions. The Scot is not usually blameworthy in this respect, and probably the fault lies with ourselves in not sufficiently advertising the claims of our association.

CHANGES REQUIRED IN THE ASSOCIATION.

I have for some time been convinced that if this association is to make the headway which, according to its strength, it ought to do, some change must be introduced into its financial arrangements, and into its methods of attaining its objects. We are a democratic body. We are not tied down by any fetters, and we are not reduced to any particular line of conduct. We have an elastic constitution—a constitution which can be altered at any time at the will of the members themselves, and to be able to do so is a great advantage in a progressive society like ours.

When I look into the original constitution of the association I find that one of its objects was the formation of "a museum and library, suitable for the general information and reference of members," and one of the sections of the constitution bears out that "the association may receive, from time to time, donations to its funds, museum, and library." This constitution was drawn up at the first meeting of the association, in March, 1877, and ratified at the annual general meeting in the following year, and all that is involved in this constitution is covered by the revised constitution of three years ago. The first reference to this question of forming a library, etc., occurs in the president's address at the opening of session, 1879-80, when Mr. Dunn, the then president, said that "the establishment of a reading-room and library for gardeners would be an important adjunct to the association, because if the gardening profession was to advance, and higher remuneration to be obtained, the best way to attain this desirable result would be for gardeners to give themselves a greater name and hold in the country, by a more skilled practice, and a higher knowledge of their profession."

From a perusal of the report of 1884-85, one would almost imagine that the library had actually come into existence, for it is there stated that "The association has received from Dr. Masters his work on 'Plant Life,' as a donation to the library, which is in course of formation, and will be opened to members as soon as the necessary room and appliances are obtained." This optimism, however, is soon dispelled, for in the presidential address of the following session we find it stated that "the formation of a museum and library has made slow progress towards its accomplishment, but, like all great works, it must necessarily take time. We have already formed a nucleus of a library, but we cannot do all that is expected of us in one day, therefore, it still remains for the association to persevere and carry to a successful issue the uncompleted parts of its programme," and in the opening paragraph of the report by the Council for the same session it is stated that "The Council of the Scottish Horticultural Association, in presenting their ninth annual report, have to state that, while the various objects of the association continue to receive the careful attention of the Council, they regret that the want of funds has not yet enabled them to open a reading room and library: they would earnestly impress on the members and friends of the association throughout the three kingdoms the necessity of making every effort so as to enable the Council to carry out this desirable object." Notwithstanding this appeal, nothing further seems to have been accomplished so far, and it is not till 1892, seven years afterwards, that we find the matter again referred to. In the opening address of that session, the president, my esteemed friend, the late Mr. Welsh, referred to it thus: "We have by no means exhausted the objects for the attainment of which the association was formed. In fact, we are only now getting into such a financial position as to warrant our looking forward seriously to the possibility of being able to carry out some of the more important proposals which for the last fifteen years have been lying in abeyance." Five years elapsed before any further reference is made to the matter, but in the address from the chair at the opening of session 1897, we find extremely optimistic views put forward. Mr. Todd, the president for that year, took as the subject of his address, "Our Association: Its Achievements and Aims," and, in referring to this matter, he said: "Our achievements in the intellectual and educational spheres we may well be proud of, but they do not exhaust the good work we have done for gardening and gardeners. Successful as these have been, our success in exhibition work has been still greater, and though, perhaps, outside the sphere of the objects we first aimed at, has naturally allied itself with our other work, and has been so conducted that the exhibitions under our auspices have proved object-lessons to every floral society in the kingdom."

Proceeding, Mr. Todd said: "What, then, of our aims? Is our future merely to be a repetition of our past, or rather shall we look upon what we have done as an earnest of the things that we shall do? Our aims, I hope, as an association, will rise yet higher than the reading and discussion of papers, profitable as these have been. A horticultural institute was one of our early dreams, and I see no reason why, by and by, we should not have one. A home of horticulture, where a systematic course of theoretical and technical instruction will be available to all young gardeners, and where an examining body would grant diplomas of fitness that would be a certain passport to all gardeners possessing them to the highest places of preferment in the profession. Why should there not be a faculty of gardeners, admission to which would be a certificate of fitness? It is often said that the remuneration of gardeners, is, as a rule, so low that there is no encouragement to pursue higher attainments. No doubt wages of gardeners are much too meagre for the varied services rendered and expected, but still we find the highly qualified men generally get the few prizes that are going, and I am certain that high attainments will always find some fitting reward, and many an employer would soon see it to be to his best self-interest to retain the services of a really qualified man, even at the cost of a considerable rise in wages. It would be a crowning success to our association to be the means of thoroughly educating and fitting gardeners for the very best positions, and also of effecting the long wished-for improvement in remuneration."

(To be continued.)

Vegetable Marrows.—If convenient frames are at hand sow a few seeds in pots and place in heat. Grow the plants on a mild hotbed in a frame, and they will give a few early cuttings of this useful vegetable before the main crop comes in. Close the frames early during the afternoon, and syringe the plants to ensure active growth. Be careful to fertilise the flowers while they are dry, during the middle of the day.—C. F.

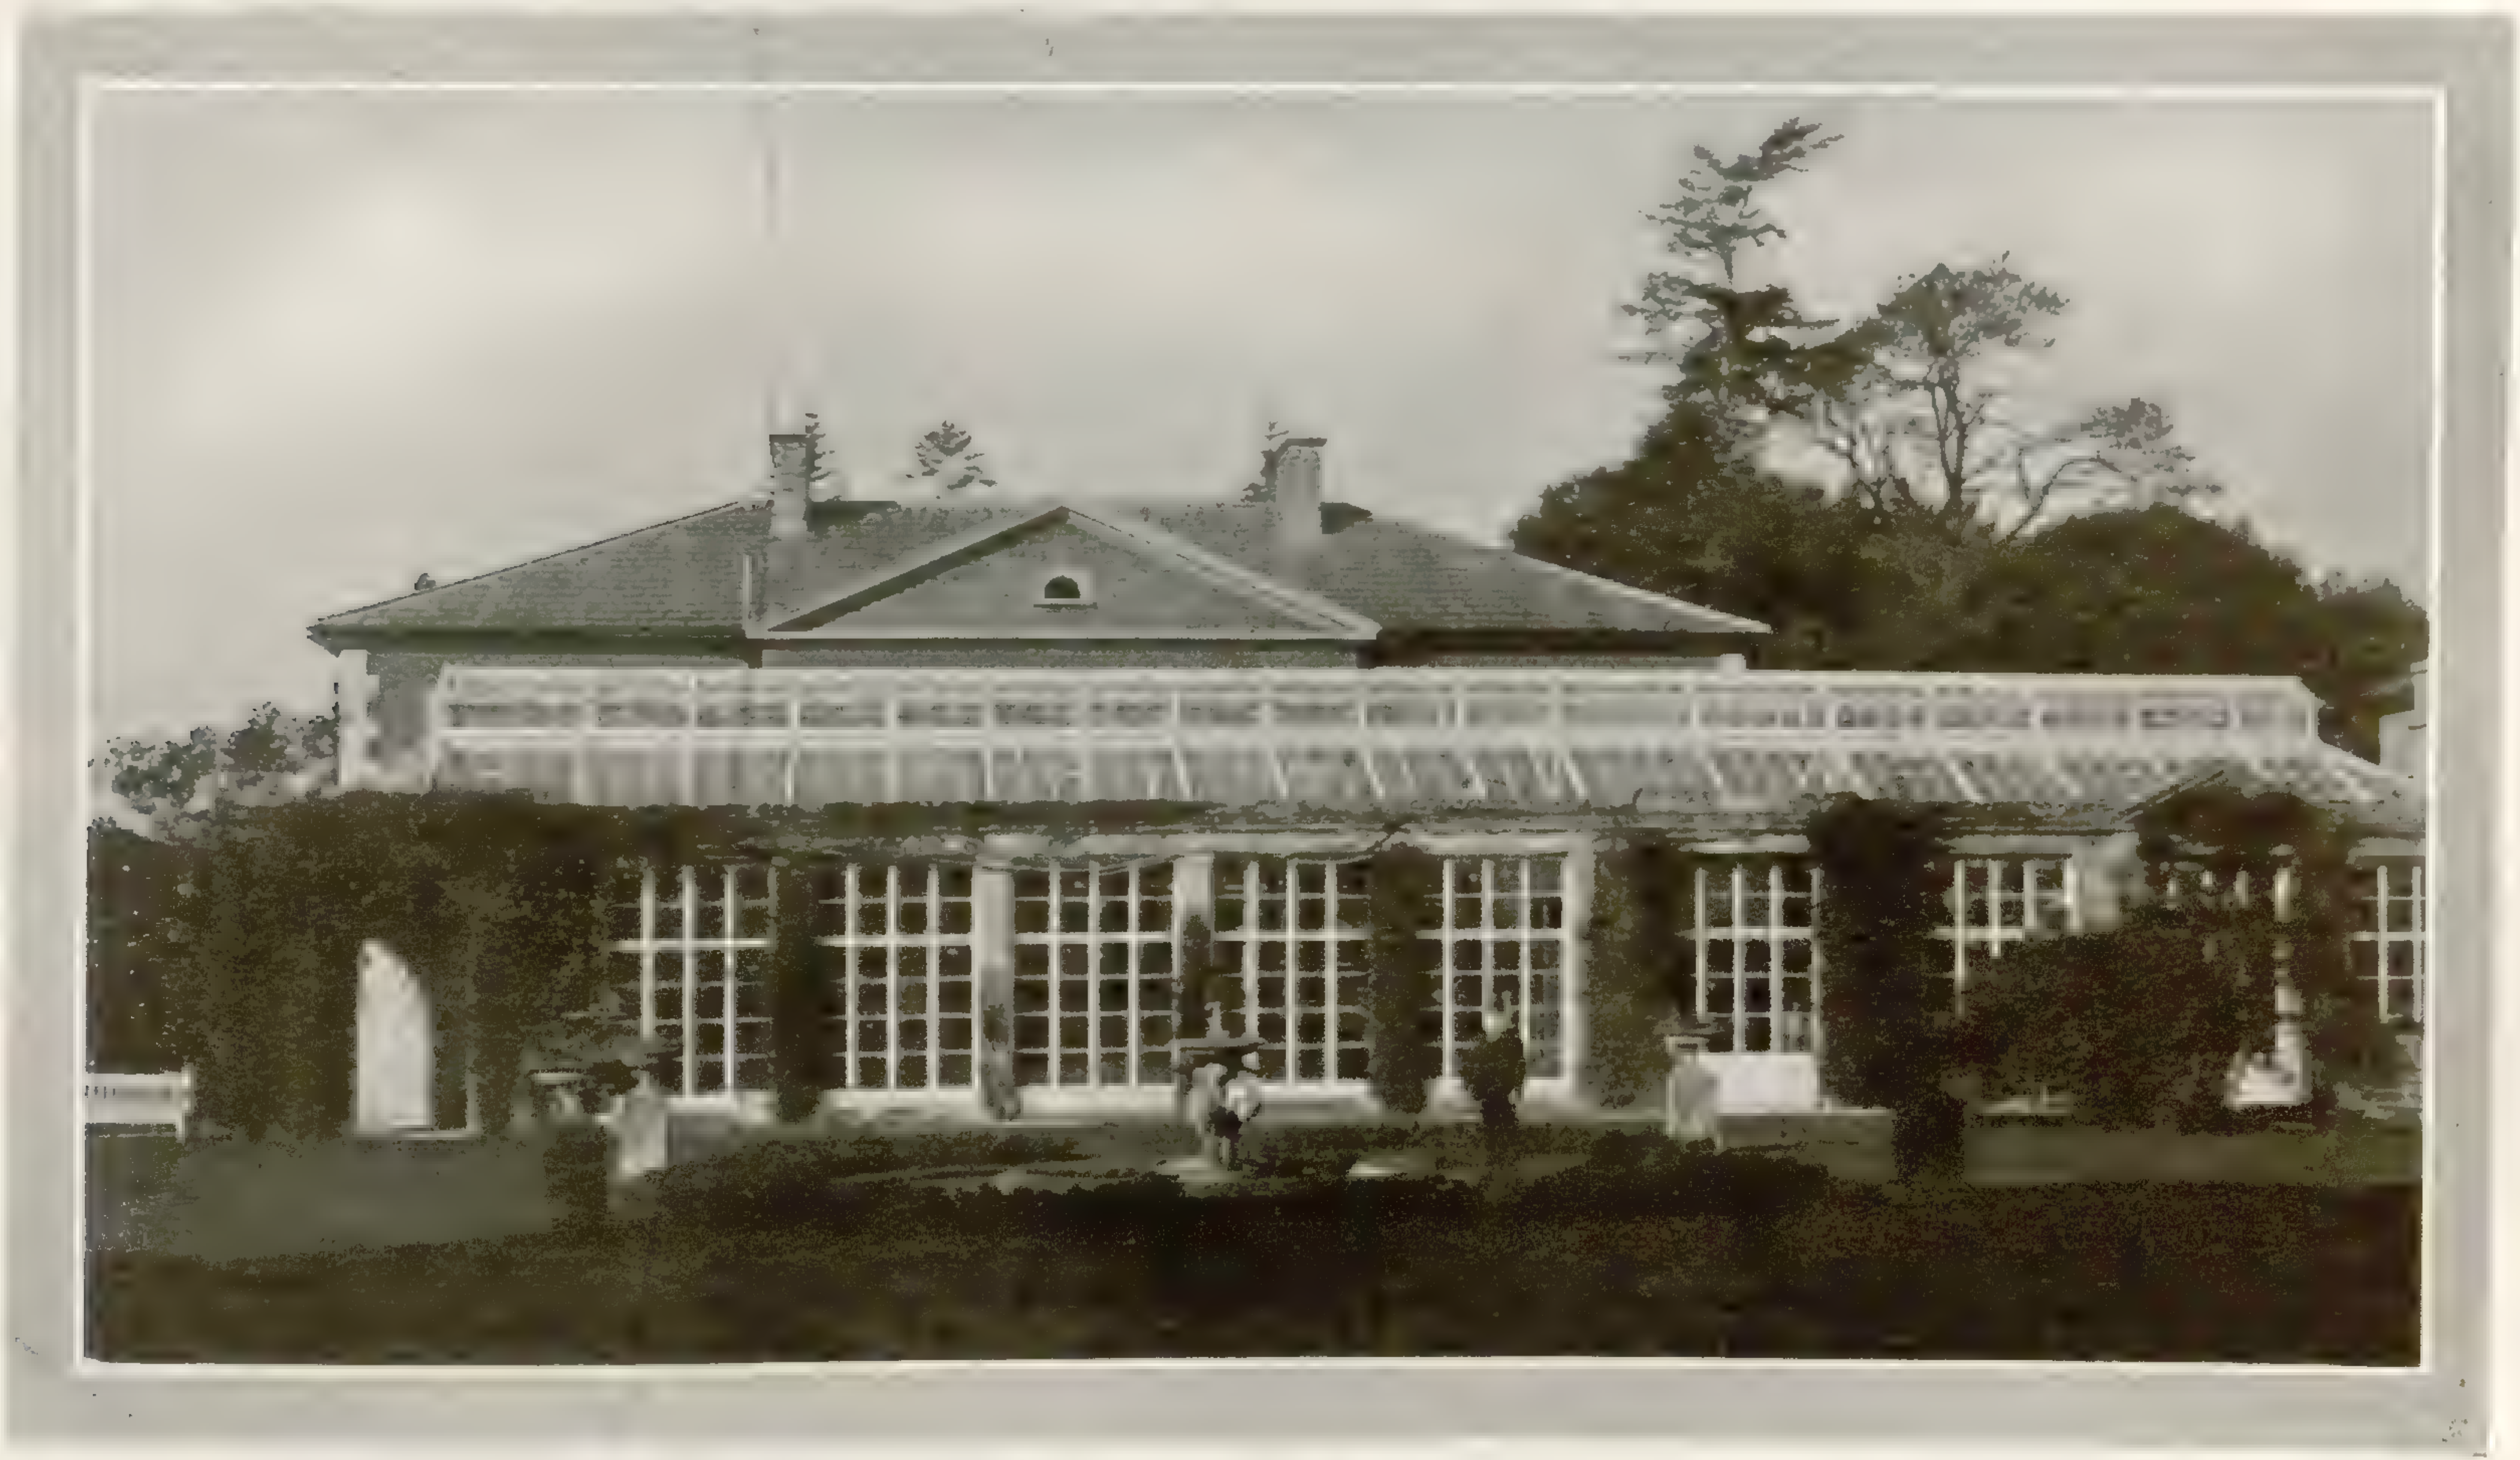
Cotyledon fulgens.—This is far better known in gardens as Echeveria fulgens, but by botanists all the echeverias are now included in the genus Cotyledon. Most of them are grown for the sake of their ornamental leaves, which are of a stout, succulent nature, but this species is well worthy of attention for the sake of its showy blossoms, an additional item of interest being the fact that in the warmest end of the greenhouse they are borne during the winter months. The leaves are somewhat ovate, of a pale glaucous green, and borne on a stout stem about six inches high. The flowering branches, which are often quite a foot in length, bear a number of rather short tubular red and yellow flowers. This species, which is a native of Mexico, is well worthy attention as a winter-flowering plant for the greenhouse.—W. T.

A SKILFULLY RENOVATED CONSERVATORY.

In connection with the series of articles on plant and fruit houses and garden pits and frames that we have published within the past twelve months, we have illustrated numerous structures for the purpose of showing the great advance that has been made in this branch of horticultural activity, and assisting our readers in selecting glass houses specially adapted to their varied requirements. These articles, and the illustrations, have, we are gratified in knowing, proved of much interest and extremely useful to our readers, and we suggest that those who do not bind the year's numbers should preserve the issues in which the articles appear in such manner as to admit of their being readily referred to. There is, of course, another side to the building art in its relation to the garden, and that is the modification of existing structures for the purpose of bringing them more into line with modern ideas, or, it may be, adapting them to the altered conditions that frequently obtain. We have not in view alterations in the ordinary span-roof and lean-to glass-houses, that form so important a feature in a well-furnished garden, but the adaptation to present-day requirements of spacious conservatories and winter gardens, and, it may be, orangeries that were built in accordance with the views that were held in the early days of providing structures for the shelter of tender plants.

This aspect of the builder's art, although necessarily of less importance than of building new houses, is one that requires careful consideration, and imposes a somewhat severe test upon the judgment and taste of those who undertake such work. The conservatory in the gardens of Buxted Park, the residence of the Hon. H. B. Portman, is a case in point. This spacious structure was built many years ago, how many it would be difficult to say, but it is evident that it belongs to the period when lightness in design was not regarded as an essential feature of the conservatory. In its original state it appeared to belong to the transition period of conservatory building, or, in other words, to the time between the old orangery and the modern conservatory. It was spacious, and given a site along one side of the flower garden that is contiguous to the mansion, it served the purpose of accommodating large numbers of flowering and ornamental-leaved plants, and of blocking out some prominent outbuildings, but in the latter respect it was less effective than it now is.

This conservatory is connected with the mansion at the end on the right-hand side of the picture, and the present owner of the Buxted Park estate, when he came into possession, decided to modernise it, with a view to better adapt it to the requirements of plant life, and to admit of it being more fully utilised. The work of making the alterations was entrusted to Mr. J. Gray, the well-known horticultural builder, of Chelsea, and, writing with a full knowledge of the original and present form of the structure, we feel we are fully justified in stating that the manner in which the modifications have been effected is deserving of the highest praise. Originally the roof was a lean-to, with a rather low angle, and it had three defects—it admitted less light than the plants required, it gave the structure a rather flat appearance, and it failed to screen a much smaller part of the building than is at the present the case. By the substitution of a lantern roof for the old lean-to the appearance of both the interior and exterior has been immensely improved. It has also been possible, in making the change in the roof, to greatly improve the system of ventilation, it being now possible to readily adapt the admission of air to the requirement of the plants, and to effect changes in the most expeditious manner. In mentioning the success achieved by Mr. Gray in the renovation of the fine old conservatory at Buxted Park it should be added that, as so well known to many of our readers, his chief business is the building of new houses, and that evidence of his skill may be seen in all parts of the country.



THE CONSERVATORY AT BUXTED PARK
Which has been skilfully renovated by Mr. J. Gray.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

CLEANING THE PLANTS.—It is at this season of the year that insect pests are most troublesome, and close and constant observation is necessary to prevent injury to developing flower scapes and young growths. It is through the winter months that thrips are most troublesome in the cool houses. The developing growths of odontoglossums are a haven of refuge for the pests at a season when it is practically impossible to spray or dip the plants. Vaporising is all very well and most effectual where the pests are to be got at, but when the thrips have established themselves in the enveloping leaves of a new growth there is little prospect of fumigation or vaporising being effectual. With the return of brighter days spraying at regular intervals may be done when the outside conditions are favourable as possible, but the direct rays of the sun must not reach the foliage of the plants before the insecticide has had time to evaporate. In the early season it is desirable to see that all excessive moisture has dried from the new growths before night. If moisture has collected in the centres the plants should be laid on their sides, so that it may drain out on to the leaves, from which it can be removed with a soft sponge. The safest way I find to keep insect pests in check is to commence early in the year and spray at regular intervals; prevention is better than cure, and it is only by following a regular system that we can hope to keep our plants free from trouble. Plants that have been dormant should be carefully examined for scale and other insect pests, which may secrete themselves in the loose, dead leaf scales or outer coverings of the growths. It is surprising how quickly these pests seem to make their appearance as soon as the plants show signs of renewed growth.

RED SPIDER.—After a prolonged use of artificial heat such plants as phaius, cymbidiums, miltonias, sobralias, etc., are generally attacked by red spider. This pest usually attacks the under sides of the leaves, and may be held in check by syringing once or twice a day with rain water. Vaporising destroys the insects, but the safest way is to sponge the foliage and occasionally spray with some safe insecticide.

SLUGS AND SNAILS are disastrous to the advancing flower spikes of the odontoglossums and other cool-house orchids at this season of the year. The spikes may have a small piece of cotton wool wrapped around their base; this does not wholly prevent the slugs attacking them, but it forms an obstacle difficult to surmount. Some bran or brewers' grains laid about the stages, on pieces of glass or broken crocks form traps, and should be examined during the evenings and in the early morning. Hollowed halves of potatoes also form a good feeding ground, and as soon as lettuce leaves are procurable they should be laid about the stages and on plants that slugs frequent, and if these are examined every night and morning it will assist in keeping the pests under. — H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

CLERODENDRON THOMSONÆ. — C. Thomsonæ or C. Balfouriana is a deciduous roof climber of free flowering habit. When cultivated as a pot plant or in a large tub its management becomes very simple, the wood ripening up well and producing abundance of flowers during autumn. When cultivated as a specimen plant it is best trained on strands of twine running over the roof and placed near the glass. The stems may be removed from this position and trained upon a balloon trellis, or whatever shape is required, a few weeks prior to the development of the flower buds. Propagation is easily effected by rooting cuttings in the usual way, plunged in bottom heat and kept close for a few weeks. The cuttings are best inserted during the spring months, selecting shoots three or four inches long, and, if possible, with a heel of the old wood attached. As soon as the pots are filled with roots the plants may be potted singly and grown steadily in a temperature of 55 to 60 degrees. If small decorative stock is desired the growths must be stopped two or three times during the earlier stages, and the roots be restricted to small pots; four-inch or five-inch pots are of useful and serviceable size.

CLERODENDRON FALLAX is of exceptional merit, and most valuable as a winter flowering subject. Its intense scarlet flowers produced over green, healthy, vigorous foliage, have a charming effect during the dull season. It may be propagated during spring, either from seeds or cuttings; seeds may be sown at the present time, and the seedlings potted singly and grown steadily during the summer. Where there is a stock of old plants these may be started into growth immediately, and as soon as the shoots have developed a few leaves they may be removed with a heel of the old wood, placed singly in small pots previously filled with a sandy compost, and be plunged in a brisk bottom heat of 75 to 80 degrees; they will then root in a few weeks. They must be kept close in a propagating case, shaded from the hot sun, and be occasionally sprayed to prevent the foliage from drooping. When rooted, admit air carefully, and repot as required. The compost previously recommended will also be found suitable for C. fallax. During very hot sunshine the plants enjoy a light shade.

ACHIMENES IN BASKETS.—Achimenes are ideal subjects for baskets on account of their natural drooping growth and extremely free flowering habit. Prepare an open compost of rough, lumpy peat and loam, with about one-sixth part of Bedfordshire sand and sheep manure. Line the baskets with green moss and fill up to within an inch of the top with the compost advised; place the tubers about an inch apart evenly over the surface, cover them with rather fine soil, and thoroughly water in. Allow the baskets to drain for a few hours, and afterwards suspend them from the roof of the intermediate plant stove. Very little other attention will be required until the tubers have commenced to grow freely. When the baskets are afforded a light and well ventilated position a strong, short-jointed, free-flowering growth is secured.—John Donoghue, Bardon Hill Gardens.

THE FLOWER GARDEN.

DAHLIA TUBERS which have been started in heat, as advised earlier, will now be making good growths for cuttings. The shoots should be taken off when about four inches long and inserted singly in pots filled with sandy soil, plunging them in a slight bottom heat.

CANTERBURY BELLS, FOXGLOVES, HOLLYHOCKS, PANSIES, SWEET WILLIAMS, PINKS, etc., which have been wintered in nursery beds, should be put into their permanent quarters without delay. The Canterbury bells are valuable for the mixed border, and provide a fine show in early summer. Foxgloves are highly recommended for grouping boldly in the wild garden, when an excellent effect may be obtained. They are equally suited for growing among low shrubs, above which the flower spikes may tower. The single pyrethrums are highly appreciated for cutting early in the season, and a good batch should be grown specially for this purpose. They are easily raised from seed, and good flowering plants may be obtained from a twelve-months' growth; raising a stock from seed is very interesting and useful work. The same may be said of aquilegias, the dwarf, long-spurred varieties providing a selection of lovely colours; for grouping in the mixed borders they are indispensable. Slugs are particularly fond of the young growths of pyrethrums and aquilegias, therefore some preventive measures must be taken. Gladioli may be planted between the aquilegias, and thus a second crop of bloom can be obtained without disturbing the latter. The various pinks are excellent for grouping in the front of the borders, and it is advisable to work a small quantity of sand or wood ashes into the soil when planting. Pansies require liberal treatment, and should be planted in irregular drifts in the foreground of borders, when they give a very pleasing effect. Hollyhocks are noble subjects for the background, and although addicted to disease, good results are usually obtained by raising seedlings annually.

HARDY ANNUALS.—Providing the soil is in a fit condition, the first sowing may now take place. The surface of the beds should be raked down finely, and a calm day is essential for sowing the seeds. Mignonette should be given rich soil, which, if deficient in lime, may have some old mortar rubble added. The very fine seeds, such as those of Shirley poppies, clarkias, godetias, etc., may, with advantage, be mixed with dry sand which ensures a more even distribution of the seeds.

HALF-HARDY ANNUALS.—A slight heat is necessary to raise the first sowing, and a warm greenhouse or a frame on a gentle hotbed will be found a suitable place. Pans or boxes may be used, and these should be filled with a mixture of one-third loam, one-third leaf-soil, and one-third sand, finely sifted, and thoroughly mixed. Water very carefully after sowing and shade from bright sun. Subjects to sow now are asters, nemesia, nicotiana, dianthus, petunia, zinnia, marigold, marguerite, carnation, phlox, Dimorphotheca aurantiaca, perilla, tropaeolum, etc.—E. C. Pooley, Gnaton Gardens.

FRUITS UNDER GLASS.

VINES.—All late vines should be ready for starting, as with increased light and solar heat the sap will be soon on the move. All the houses should be made scrupulously clean. Iron work should be painted over with raw petroleum to kill all insects in hiding, and remove rust; locks, bolts, and hinges should be oiled with good machine oil, and, as a finish, clear the borders of rubbish and top-dress, if necessary, with some prepared loam and bone-meal. If the border is very dry give a thorough soaking of water. It has become an established rule not to disturb the roots of vines after the autumn; but with outside borders I do not think it much matters when this is effected if the roots are in a bad state and in sour, water-logged soil. The existing state of things cannot be altered until the work is done, therefore the sooner it is taken in hand the better the chance of improvement. Alicante and Gros Colmar root far more freely than Muscats and Madresfield Court. In late houses it is not necessary to tie down the rods, as they will break naturally; plenty of air should be given in the early stages.

VINE EYES.—Those growing strongly should have a shift into slightly larger pots, and those that are in pans or boxes should be separated, put into small pots, and again placed in a close frame until established.

POT VINES.—Thin the berries as soon as they are ready, and do all the thinning at once, as a better shaped bunch will result. Keep the temperature of the house or pit at from 70 to 75 degrees, damping down as often as is necessary, and admitting fresh air on all favourable occasions. A little stimulant should be given at this stage, in alternate weeks, and in small doses, taking care not to allow the pots to become really dry, or failure will be an inevitable result.

FIGS.—These will be growing well now, and the temperature of the house may be raised to 65 degrees. Thin the shoots by disbudding when too many are showing, leaving only those wanted to make a well-balanced tree; and as soon as the shoots have made five or six leaves they should be pinched, but do not pinch all the shoots at once, or the sudden check may cause the fruits to drop. Young plants may now be planted in permanent borders with every chance of success. Good varieties that can be relied on to crop regularly should be chosen. The old Brown Turkey is hard to beat for all purposes, and is a very free setter, either in a border or for forcing in pots; it is quite the best for a main crop. Bourjassotte Grise is an abundant and constant bearer, and St. John's and Negro Largo are productive. When making a border I would advise the use of three parts loam and the remainder made up of mortar and brick rubble and bone-meal. Make all very firm by ramming.

EARLY PEACHES.—Continue to disbud shoots and fruits, as the earlier this is done the less will be the strain on the resources of the tree. When the shoots have grown above the wires to their allotted space, the points may be pinched out. The succession house should be slightly fumigated as soon as the trees are out of flower, and this will be found to check aphis. At this period the trees should be well syringed, both morning and evening, taking care not to steam the pipes more than is absolutely necessary. A little air should be admitted by the top ventilators as soon as the temperature begins to rise.—W. A. Cook, Leonardslee Gardens.

THE CORONATION FLOWER.

While the question of a flower for the Coronation has been under review in some of our daily papers, and a choice has been made of the sweet pea, is it not a little odd that a native of Sicily, and not a British subject should have been selected? The sweet pea (Lathyrus odoratus) was introduced, according to the authorities, about 1700, and now has become one of the most extensively cultivated and popular flowers in the United Kingdom. Still, this does not dispel the fact that it is an exotic. On an occasion like the Coronation the aim should be to be British—British in sentiment, British as to the clothes we wear, and British in the selection of a flower to adorn our buttonholes. For that day, and that display, we should allow everything of foreign origin to remain in store, and make use of our own manufactures and native productions for all outside embellishment.

In this case, why should a foreign flower be worn in preference to a truly British one, when we have a choice of such things as roses, carnations, and pinks? These are decidedly more British, and are, at the least, equal, if not more than equal, in point of merit, to sweet peas, and have as much chance of being in bloom at the Coronation as the Sicilian plant. X. Y. Z.

WOLVERHAMPTON
GREAT FLORAL FETE.
July 11, 12, and 13, 1911.
£900 IN PRIZES.
Schedules on application to the Secretary.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Broughty Ferry Horticultural Association.

The monthly meeting on February 21 was a public one, a number of ladies and gentlemen being present, in addition to the members of the association, to hear a lecture on "Preserving Ripe Fruits and Mature Vegetables" by Mr. George P. Berry, Horticultural Lecturer in the East of Scotland Agricultural College, Edinburgh.

After dealing in a general way with fruit rooms and the storing of apples and pears in such structures, Mr. Berry commended cellars or disused ice-houses as being easily convertible into first-rate fruit-rooms. Whatever the shelves were composed of, a layer of sifted burnt clay ought to be spread on the top to place the apples upon. This seemed to preserve the natural flavour of the fruit in a manner which was not possible with any other substance he knew, and the keeping qualities were considerably prolonged.

In dealing with bottling, the lecturer recommended gathering the fruits in the morning; it did not really matter whether it was wet or not, but care ought to be taken not to break or bruise it. Exhibiting a quart sized bottle, which he recommended as suitable, Mr. Berry explained in a very plain and practical manner the superiority of these over those used in French methods; the price was 4s. 6d. per dozen bottles. Going on to describe the process, he advised thorough cleansing of the bottles with hot water, then packing the fruit as closely as possible, allowing it to stand up to the neck of the bottle, and then adding sufficient clean water to just cover the fruit. This done, adjust the glass stopper and rubber washer, screwing on the tin cover as tightly as possible, and place the bottles with their contents up to the shoulder in water in any cooking utensil which would accommodate them. A spirit lamp or ordinary fire could be brought into requisition to bring the water in the utensil up to 145 degrees, this temperature being maintained for one and a-half hours. At the end of that time it would be found that the lids were slack, and they should be tightened, using a cloth in the hand. When cold, the lids should be rubbed with an oily cloth to prevent rusting, and the bottles be stored away in a cool dark press or cellar.

In the case of ripe fruits to be used for dessert purposes, he thought it an advantage to make a syrup of sugar, using half a pound of pure cane sugar to a quart of water, pouring this over the fruits after filtering it through a flannel cloth.

When dealing with mature vegetables Mr. Berry recommended first boiling peas and beans taken from the pods; this could be done in an ordinary saucepan which contained as much water as would nicely cover them. After allowing them to cool slightly the seeds and water should be poured into the bottles and the cover adjusted, and sterilisation proceed as advised for fruit. Sulphate of copper, which keeps peas, etc., a bright green colour, ought not to be used, because poisonous.

A number of questions were put to Mr. Berry which he answered in a satisfactory manner, after which he was accorded a hearty vote of thanks.

The exhibits consisted of twelve magnificent cyclamen from Mr. George Reid, Invertay Gardens; hyacinths, tulips, and Primula obconica in 6in. pots, as well as a bowl of fine flowers of helleborus from Mr. Wm. Grant, Fernhall Gardens. Mr. D. K. Meston, The Lodge Gardens, set up two pots of exceedingly well forced seakale, White Lily, and also a bundle of thongs which had been removed from the plants, and were just starting into growth. The President spoke highly of the quality of this exhibit, and explained at some length to the audience the method of growing seakale on the one-year system. Mr. George Masson, Ayestree Gardens, showed a malformed arum, while the President showed a flowering plant of Hæmanthus natalensis, vases of narcissus, tulips, Primula obconica grandiflora, etc.

A vote of thanks to exhibitors and to the President, Mr. James Bethel, brought a profitable evening to a close.

Reading Gardeners' Association.

The fortnightly meeting of this association was held in the Abbey Hall on Monday, February 20, the President, Mr. Alderman Parfitt, occupying the chair, and again there was a large attendance.

The minutes of the last meeting were read and confirmed, and the President threw out some useful hints for the benefit of the younger members with regard to self improvement.

On the proposition of the President, it was decided that a resolution of condolence on the death of Mr. Chas. Foster be conveyed to Mrs. Foster by the hon. secretary, by letter. This was carried in silence.

Mr. Dore being still too unwell to give his paper, the hon. secretary had enlisted the sympathies and services of Mr. T. Tunbridge, and he most kindly came forward with a paper on "Winter and Spring Bedding." Mr. Tunbridge is a thorough master of this subject, and dealt with the matter in hand in his usual lucid and practical manner. His remarks with reference to the raising of plants by seed sowing and by propagation, the arrangement of harmonies and contrasts in colours, and the naturalisation of plants and bulbs being followed with deep attention. On resuming his seat Mr. Tunbridge was warmly applauded, and in the lengthy discussion which followed the paper he was heard to advantage in replying to the many questions put to him.

Mr. H. C. Loader, head gardener to M. H. F. Sutton, Esq., Erlegh Park, staged a really splendid group of Lachenalia luteola which were greatly admired, the blooms and growth being of great substance. Several new members were elected.

The annual tea and entertainment in connection with this association took place at the Abbey Hall (by permission of Messrs. Sutton and Sons), on Wednesday, the 15th ult., when, at six p.m., about 100 members and friends sat down to an excellent repast. Mr. Alderman Parfitt presided, and read an expression of regret from the vice-president that he was unable to be present at the tea, but hoped to join the company during the entertainment, later. Mr. Arthur W. Sutton also wrote expressing regret at his enforced absence, and wishing all present an enjoyable evening.

The meal having been despatched, the hall was quickly cleared of tables, etc., and an audience of between 700 and 800 quickly assembled to enjoy the splendid entertainment provided for the evening.

Through the agency of Messrs. Maskelyne and Cooke, of St. George's Hall, London, a particularly talented and high-class party had been engaged, and a fine programme was rendered to the great delight of the large gathering.

Mr. Archie Naish in his humorous sketches at the piano showed his mastership of the instrument, and also provoked the risible qualities of the company in very marked degree. The Appenzellers, by the clever manipulation of their quaint instruments and their delightful rendering of vocal items, won well-merited applause and consequent encores, while Mr. Ernest Sewell, in his clever paper-tearing and subsequent "Living Marionettes" fairly brought down the house.

The entertainment was unanimously voted to be one of the best ever held under the auspices of the association.

The Elstree and Boreham Wood Horticultural Society.

A splendid meeting was held on Tuesday, the 14th ult., in the Church Room, Elstree, and was largely attended. Messrs. Cox and Townsend, of Messrs. Sutton and Sons, were the lecturers, their subject being "Hardy and Half-Hardy Annuals." The former manipulated the lantern, whilst the last-named delivered the lecture. This was of a most instructive and interesting nature, and the many excellent coloured and other slides thrown on to the sheet by Mr. Cox were greatly appreciated, and illustrated the many and great advantages that might be made of this beautiful and interesting class of plants when their cultural details are studied a little. At the close of the lecture several questions were asked of Mr. Townsend, who replied in a prompt and practical manner. At the close a hearty vote of thanks were accorded these gentlemen for their kindness in providing such an enjoyable evening; also to the chairman, H. Shephard, Esq., who so ably filled his office. The society continues to make excellent progress. During the evening thirteen new members were elected.

Bournemouth Gardeners' Association.

The first paper of the new session was one on "Conifers," written by Miss C. Agnes Rooper, Penselwood, Bournemouth, and read by Mr. W Reeves, the hon. treasurer, on February 21.

Miss Rooper takes a great deal of interest in horticultural matters, and does much every year to support the Bournemouth Gardeners' Association. Mr. Reeves brought specimens of more than sixty distinct conifers, nearly all of which were referred to by Miss Rooper in her very interesting paper.

Some grand specimens of cyclamen and cinerarias were staged by Messrs. C. Nippard (the assistant secretary) and C. Pearce respectively, and the highest award was made in both instances.

Miss Rooper said that the conifer family was spread all over the world, some of the finest specimens being found in North America, and especially in California. The conifers are distinguished from any other order of plants by the peculiar structure of their wood, their resinous secretions, the form of their leaves, and the extreme simplicity of their flowers and fruit. Miss Rooper said that some authors include in this family the group of trees and shrubs known as the taxads, of which the yew is the type; but the fruit of the taxads is very different from that of the true conifers, with its leathery scales and numerous seeds. The taxads are considered a distinct order in themselves, but closely associated with the conifers.

The two orders are of the greatest importance to man, in many respects supplying the most valuable timber for constructive purposes. Their resinous secretions and products are important articles of commerce, largely used in many of the arts. No other family of trees and shrubs produces so many ornamental specimens to adorn our gardens and parks; and there is no race of plants of greater ancestry, as traces of conifers and yews have been found in the most ancient rocks near Lulworth. On the side of the cliffs about a mile to the east of Lulworth Cove there is quite a large group of pines to be seen, or rather their petrified stumps. Of yews there is a remarkable grove in Norbury Park, in Surrey, and on the South Downs, near Chichester.

Miss Rooper referred to the great number of distinct species, and to the fact that many specimens of conifers did so well growing in shallow soil on steep, rocky slopes; to the great vitality of the roots, to the considerable differences in the depth to which the tap-roots penetrate the soil, and to the extent and direction of their branching, dependent mainly on soil and other conditions. The writer of the paper referred to the great age to which some species lived, and to the durability of the wood, instancing the old doors of St. Peter's, at Rome, made of cypress wood that lasted eleven hundred years, and which were quite sound when removed to another place by the Pope's orders. References were also made to planting and insect pests.

A discussion followed, and votes of thanks were accorded the chairman, Mr. Cockman, and Miss Rooper.

Dundee Horticultural Association.

At the ordinary monthly meeting, recently held in the Technical College, the President, Mr. William Christeson, presided, and during preliminary business seven new members were elected.

Mr. J. Birse was the essayist, and had for his subject "Insectivorous Plants." Dealing with this matter in a general way, Mr. Birse considered that the plants were more curious than beautiful, and in referring to the natural provisions they possessed for trapping the insects, and afterwards assimilating food from them, he mentioned the sundew, butterwort, Venus's fly-trap, nepenthes, sarracenia, darlingtonia, etc. He gave details as to their habitations, and helpful suggestions for their cultivation. A good discussion ensued.

The annual social and dance was held on the 10th inst. W. S. Melville, Esq., the president, presided at the concert, when an enjoyable programme of music was well sustained. The Chairman gave some excellent advice to the young men present regarding their "birthright" of technical education, urging them to take every advantage offered by the association to improve their knowledge and mode of address. He hoped they would uphold their excellent traditions in 1912, when the British Association would visit Dundee. A dance followed, when the young folks thoroughly enjoyed themselves, Mr. John Campbell making an efficient master of ceremonies.

Birmingham Gardeners' Association.

There was a good attendance of members on February 20, to hear Mr. P. E. Martineau give a lecture on "Afforestation of Waste Land," illustrated with lantern slides. Mr. C. H. Herbert (the vice-chairman) presided.

Mr. Martineau, who is secretary of the Midland Re-afforesting Association, Birmingham, began by drawing a distinction between ornamental sylviculture and forestry —the one decorative and the other commercial. Statistics were given of the trees found to be suitable for afforesting the pit mounds and other waste land in the "Black Country," and of the comparative successes accruing from the practical experiments under the Midland Afforestation Association. Alder, wych elm, ash, and poplars had been proved the most suitable for the purposes indicated, and according to the nature of the soil and position. The extermination of scrubby shrubs and weeds was recommended. Coniferous trees, by reason of their evergreen foliage, are adversely affected by the atmosphere of the "Black Country," more especially when permeated with sulphuric or carbonic impurities. The lecturer, however, opined that the ordinary coal smoke did not materially affect the health of deciduous trees.

A large series of lantern-slide illustrations, showing the comparative growths of several young plantations in various stages of culture, and also of well-formed and ill-formed timber trees, were thrown upon the screen.

The instructive and highly interesting lecture was followed by an animated discussion, and the various questions were satisfactorily answered by Mr. Martineau, an important one being in regard to the chemical nature of the "slag" and the manurial properties of basic slag. Mr. Martineau also incidentally remarked that vast quantities of the slag are being utilised by various leading railway companies for metalling their roads.

A vote of thanks was accorded to Mr. W. Preston, Lawn House, Edgbaston, for three large pots of narcissi, the one of N. poeticus being remarkably large and fine. A cultural certificate was recommended for the whole exhibit.

Bristol Gardeners' Association.

The usual meeting was held on February 23 at St. John's Parish Rooms, Mr. Hayball in the chair. Mr. Edwards, representative of the Bath Society, read a paper on "Asparagus." The lecturer said that in growing asparagus much depended on the nature of the soil, which should be deep sandy loam, and be liberally manured and trenched in the winter in preparation for seed-sowing early in April. He advised thinning out the seedlings to nine inches apart when large enough to handle. In the second year of growth remove each alternate plant, thus allowing a distance of eighteen inches each way in the beds, which should be five feet in width. Commence to cut when the plants are three or four years old, but do not extend the period of cutting any longer than two months. Mr. Edwards recommended seaweed as a manure, used in a decayed condition, placed on the beds after removing part of the soil. This operation is best done in February or March; the lecturer deprecated the use of manure in the winter, affirming that the proper time is when the plants are in full growth, and he advised applying nitrates in May or June. For two orchids Mr. Hunking was first, and Mr. Jennings second. In the point competition, Messrs. Woodward and Jennings received three and two respectively for Dendrobium Wardianum, and Mr. Springham three points for a dish of apples.

B.G.A., London Branch.

On Saturday, February 25, a most successful social evening was held at Carr's Restaurant, in aid of the Royal Gardeners' Orphan Fund. The chair was occupied by Mr. E. F. Hawes, and about 120 members and friends were present. The excellent programme of songs and recitations, arranged by the Concert Committee, was well received. During the evening Mr. Hawes gave a short address, and for the benefit of those present who were not members he summarised the aims and objects of the association, and directed attention to the good work it has already accomplished. The announcement that the membership now well exceeds 2,000 was received with much applause. These encouraging results, continued Mr. Hawes, were the outcome of steady growth, and have not been brought about by spasmodic efforts. A vote of thanks was unanimously accorded to the ladies and gentlemen who had kindly given their services, and the singing of "Auld Lang Syne" and the National Anthem brought a most successful and enjoyable evening to a close.

TRADE NOTES.

His Majesty King George V. has granted to Messrs. John Forbes (Hawick), Lim., Buccleuch Nurseries, Hawick, a Warrant of Appointment as nurserymen to his Majesty, an appointment which the firm previously held to King Edward VII.

His Majesty King George V. has granted to Messrs. James Veitch and Sons, Lim., Chelsea, a Royal Warrant of Appointment as nurserymen and seedsmen to his Majesty.

Messrs. Dickson and Robinson, Cathedral Street, Manchester, who recently received the Royal Warrant of Appointment as seedsmen to King George V., have been appointed by Royal Warrant seedsmen to Queen Alexandra.

Messrs. Hobbies, Lim., Dereham, have been granted the Royal Warrant of Appointment as nurserymen to Queen Alexandra.

BIG BUD IN BLACK CURRANTS.

Mr. Hammond's rejoinder seems, for the most part to relate to a number of methods of attacking the black currant mite to which I did not even allude in the letter referred to, so that I shall not attempt to follow him through the long history of his courageous, but confessedly futile, attempts to rid himself of this destructive pest. I may state briefly that my own observations (and I am a Fellow of the Geographical Society, and have even travelled as far as Kent) would lead me to exactly the same conclusions as to the absolute futility of "bud picking" and most of the other remedies from time to time recommended. I am also at one with him as to the absence of any really immune variety of black currant.

The ground so far cleared, I may pass on to one or two points which seem to require a little further explanation. Mr. Hammond seems to think that nursery and market garden practise differ so widely that there can be no fair comparison. But is this really the case? As regards numbers, we grow and sell many thousands of bushes annually, more, not less, than the average market gardener has on his premises, and, were it otherwise, this would not seriously affect the results obtained, so long as the experimental area were sufficiently large to eliminate such errors as are often induced by experiments upon a very limited number of subjects. Then, too, though the fruiting bushes in a market garden are a foot or so taller than two and three-year-old stock in a nursery, the difference is not sufficient to put them out of the range of an ordinary sprayer. Fruit is, of course, a negligible quantity in a nursery, and is generally left to the birds, but I may reassure those who may be apprehensive on this point by saying that our bushes, which are old enough, crop freely every year. The quassia and soft soap does not injure the young fruit, and the spraying time is over too soon for the edible quality to be affected later on. Mr. Hammond's statement that a little scorched foliage in a nursery "does not matter" is very wide of the real truth, and should not be allowed to pass unchallenged. Scorched foliage means stunted growth, and the well-grown trees can only be produced when growth from start to finish is unchecked by blights or remedies unskilfully applied.

I have no wish to upset Mr. Hammond's faith in greasy and other remedies, but, however these may eventually turn out, the one to which I have called attention certainly holds the field at present. It has been proved absolutely efficacious over a number of years and upon all the leading varieties in cultivation, it is cheap to make, and easy and cleanly in application. With practical growers 1lb. of practice goes further than one ton of theory, and, so far as I am aware, the lime and sulphur treatment (of which I have no personal knowledge) is the only other method for which any practical results whatever have been claimed. I hope, therefore, that Mr. Hammond and his fellow sufferers will make a fresh effort this spring on the lines I have indicated, and that the results will be beneficial to all concerned. Chas. E. Pearson, F.L.S.

Rose Juliet.—The excellent representation of this new rose in the almanack for the current year issued by the Gardeners' Magazine should do much to draw the attention of rose growers to this fine variety. It is a remarkable rose in colour, perfume, form, size, and the extraordinary lasting power which it possesses after being cut. In growth, too, it seems all that is desirable, having a vigorous constitution. Its history is simple: it was raised from a cross between Soleil d'Or and Captain Hayward; it has the colour of both in a remarkable degree, and for a hybrid brier the blooms are of rare solidity. For this rose I predict a great future, as it has all the characteristics that go to make a desirable flower.—E. M.

ANSWERS TO CORRESPONDENTS.

DISEASED CARNATION LEAVES.—J. C., Leeds: The plants are suffering considerably from an attack of Helminthosporium echinulatum, a fungus disease that frequently does a great deal of damage among carnations, especially among Malmaison and tree carnations. All badly-affected leaves should be cut away and burned at once, and the rest be frequently sponged or sprayed with a solution of potassium sulphide. A damp, close atmosphere assists the development of the disease, consequently drier and more airy conditions should be provided to combat it, and also to increase the vigour of the plants.

TOMATOES.—P. A. B., Galway: It would certainly pay you to put hot-water piping in the house, and two rows of 4in. pipes on either side would be ample. Of course, you could grow good crops without artificial heat, but even in such case it would be necessary to have a good stock of plants grown in a warm house ready to put out in the cold house in May. If there is no staging in the house you could plant three rows on each side of the central pathway, fifteen plants in each row; this would give a total of ninety plants. Supposing you obtained a dozen pounds weight of fruit per plant; this would mean a crop of about nine cwts., which, at 4d. per lb., would realise £16 16s. This all looks very well on paper, but everything depends upon your ability as a grower, and the market you can command. Then, again, if the house has a stage on either side, the accommodation will be limited; you would then have a row of plants next the outer walls, trained up near the glass, thirty plants in all, though one row could be grown on each side in pots or boxes. The plants trained near the glass would give relatively larger crops than those set out in rows on the ground; £10 would be a very good return from such a small house. On the outdoor plot probably raspberries would pay better than strawberries, but you would have to wait a whole year before they gave any returns. Potatoes, cauliflowers, or salading could be grown between the rows of raspberries during the first season, and usually a small catch crop could be taken. Where raspberries do well, and are skilfully cultivated, they will yield from three to four tons of fruit per acre, and the average price would probably be about £10 per ton, rather more in most seasons.

GARDENING IN BARBADOS.—M. D., Barbados: We are glad to know that the *Gardeners' Magazine* is of so much use to you in the West Indies. If you can grow pinks, antirrhinums, and pansies you should be able to manage pentstemons, paeonies, Kochia trichophylla, pyrethrums, perpetual carnations, Dimorphotheca aurantiaca, Ranunculus asiaticus, gerberas—on fairly dry places, hemerocallis, and probably montbretias. It appears to us that you will have to do a good deal of experimenting, and while this is extremely interesting work, it is also, at times, disappointing. The superintendents of our colonial botanic stations are usually ready to give every information possible in connection with the acclimatisation of plants and the success or otherwise that has attended the culture in their district of such plants as are familiar in British gardens. We suggest that Mr. J. R. Bovell, I.S.O., superintendant of the Barbados Botanic Station, may be able to put you in possession of information that will save you many disappointments. In the matter of roses you cannot go far wrong if you stick to the best of the tea-scented and hybrid tea varieties. What the grubs are we cannot say: send specimens to Mr. Bovell, or Mr. J. S. Dash, at the Botanic Station. Probably one of the special preparations for clearing the soil of pests would help you, but if the grubs are of good size, as you suggest, trapping with whatever material the pests seem specially fond of should not be difficult, while the regular use of the hoe for surface cultivation will materially help. Sweet peas you cannot hope to grow successfully, but the new [illegible] varieties, raised in Algiers, and supplied through most of the seedsmen, who advertise in our columns, may give you a few flowers, at any rate they are worth trying, and will not prove costly.

FORCED BULBS.—H. H., Chester: The Royal Horticultural Society is holding a two-days' exhibition of forced spring-flowering bulbs at the Horticultural Hall, Westminster, S.W., on Tuesday and Wednesday, March 14 and 15. Numerous cash prizes and medals are being offered. Full particulars may be obtained on application to the Royal Horticultural Society secretary, addressed as above.

DWARF CHRYSANTHEMUMS IN SMALL POTS.—B. P., Devizes: We have dealt with this matter on a previous occasion. For the present we may state the case briefly. Insert the cuttings early in April, either singly or several in pots or boxes; place singly in small three-inch pots as soon as well rooted, and keep in a cold frame. When about six inches high take out the point of growth, and at the end of June, or early in July, put each plant into a six-inch pot, using good and fairly substantial soil, and potting firmly. Only one shoot should be allowed to develop. After the pinching it must be carefully staked. In a dry season it pays to plunge the pots in ashes, but there should be a hard base for the pots to stand on.

EARLY-FLOWERING CHRYSANTHEMUMS.—R. C. H., Coventry: In common with the majority of other hardy herbaceous plants, the early chrysanthemums require a moderately rich soil that has been dug to a depth of not less than twelve inches, or trenched to a depth of two feet or so. Manure from an old hotbed and well-decayed manure from the stable or farmyard are the best to use in soil preparation, but should they not be available, use superphosphate, bone-meal, or some other approved fertiliser, at the rate of about 3ozs. to the square yard.

Eckford's Giant SWEET PEAS

THE FINEST BLOOMS IN THE WORLD.

A flower garden without Eckford's Sweet Peas can only be compared to a house without furniture. Sweet Peas are requisite to the small, medium, or large garden, and if you wish to have colour, effect, prize specimens, and tall plants, then send to Eckford's for your seeds. The time to buy is NOW. The firm to buy from is ECKFORD'S. No other seed specialist in the world can rival Eckford's for Sweet Peas. Larger flower, longer stems, brighter colours, and a profusion of bloom will be the result of growing Eckford's seeds.

REMEMBER GENUINE ECKFORD'S SEEDS CAN ONLY BE OBTAINED DIRECT FROM WEM. No Agents are employed.

SPECIAL NOVELTY OFFER FOR 1911.

LUMINOSA.—This variety will be appreciated for its deep coral colour, which for decoration is unexcelled, having the quality of giving off greater brilliance in artificial light than any other variety. Very scarce. In sealed packets, 7 seeds, **6d.**; 15, **1/-.**

VICOMTE DE JANZE.—A fine bold flower of exquisite shape, the standard being splendidly erect; in colour it is deep bright rose, perfectly distinct; a charming flower. In sealed packets, 5 seeds, **3d.**; 10, **6d.**; 20, **1/-.**

DODWELL F. BROWNE (Waved).—This is a very beautiful intense bright crimson, three and four flowered, almost a self; a true Giant Waved variety of intense King Edward VII. colour. In sealed packets, 10 seeds, **3d.**; 20, **6d.**; 40, **1/-.**

SAINT GEORGE.—Light orange pink standard with slightly lighter wings; almost a self; good size; slightly waved. In sealed packets, 20 seeds, **3d.**; 40, **6d.**; 80, **1/-.**

ASTA OHN (Waved).—A pretty waved lavender overlaid with rose; a very charming flower of good size and substance. In sealed packets, 10 seeds, **3d.**; 20, **6d.**; 40, **1/-.**

APPLE BLOSSOM (Waved).—This, as its name implies, is a beautiful flower of apple-blossom colour, of giant size, and, like most of the waved varieties, is a very strong grower. In sealed packets, 10 seeds, **3d.**; 20, **6d.**; 40, **1/-.**

PICOTEE (Waved).—This is one of the very finest introductions, being a giant waved flower, pure white, with a beautiful picotee edge of carmine; in most cases the flowers are borne in fours on a long, strong stem. In sealed packets, 5 seeds, **3d.**; 10, **6d.**; 20, **1/-.**

MAGGIE GERRING.—This is a decided acquisition with a bold standard of perfect shape, and beautifully balanced wings. In colour it is a soft cream, overlaid with a delightful shade of pink, which rather deepens towards the edges. It is exquisitely rich in tone when bunched. In sealed packets, 5 seeds, **3d.**; 10, **6d.**; 20, **1/-.**

FLORA NORTON (Waved).—This is a well expanded large flower. A pure self. Colour a bright blue, overlaid with faint reddish mauve. In sealed packets, 10 seeds, **3d.**; 20, **6d.**; 40, **1/-**

EVELYN HEMUS (Waved).—A warm cream shading to yellow, with a picotee edge of terracotta pink; of great size and refinement. Standard and wings beautifully waved, and nearly always four-flowered. In sealed packets, 10 seeds, **3d.**; 20, **6d.**; 40, **1/-.**

MRS. HENRY BELL (Waved).—A beautiful rich apricot ground, overlaid with a soft pink, which deepens towards the edges of both standards and wings. In sealed packets, 10 seeds, **3d.**; 20, **6d.**; 40, **1/-.**

MID BLUE.—A medium-sized erect flower of deep sky-blue It is a strong grower, very free and frequently four-flowered. Quite distinct. In sealed packets, 10 seeds, **3d.**; 20, **6d.**; 40, **1/-.**

OTHELLO (Waved).—A beautiful self-coloured giant chocolate of splendid substance and robust habit. In sealed packets, 10 seeds, **3d.**; 20, **6d.**; 40, **1/-.**

CERISE (Waved).—A fine, bold, beautifully waved, true cerise; a very strong grower, giving generally four flowers on long, strong stems. In sealed packets, 10 seeds, **3d.**; 20, **6d.**; 40, **1/-.**

SPECIAL OFFER. One full-sized packet of each of the foregoing 14 charming and Novel Sweet Peas, **12/6** post free for cash with order. One half-sized packet of the foregoing 14 charming and Novel Sweet Peas, **6/6** post free for cash with order.

SPECIAL COLLECTIONS FOR 1911.

Villa (C) Collection. 12 splendid varieties, suitable for exhibition, 50 seeds of each, **2s. 9d.**, post free, cash with order.

Villa (E) Collection. 12 splendid varieties, suitable for exhibition. 25 seeds of each **1/6**, Post free, cash with order.

Villa (B) Collection. 24 splendid varieties, suitable for exhibition, 50 seeds of each, **5s. 6d.**, post free, cash with order.

Half-Villa (B) Collection. 24 splendid varieties, suitable for exhibition, 25 seeds of each, **3s.**, Post free, cash with order.

A specially-written booklet on Sweet Pea Growing given with every order. Send to WEM for satisfaction.

FREE. Send a postcard to-day for large illustrated and coloured Catalogue. It gives full particulars of all novelties in Sweet Peas for 1911, and contains full list of all flower and vegetable Seeds.

HENRY ECKFORD, F.R.H.S., Sweet Pea Specialist (Dep. 221), WEM, SHROPSHIRE.

Two feet apart will be a good distance at which to plant them when growing them in beds. The best place in which to grow them in the majority of private gardens is the mixed border, where they should be arranged in groups, three or four plants being put in each. May is the best time for planting. Some good varieties are: Crimson Mdme. M. Masse, Harvest Home, crimson and gold; Ivy Stark, yellow; Mdme. Louise Lionnet, pink; Mdme. M. Masse, lilac; Mytchett Beauty, yellow; Mytchett White, Rabbie Burns, rose-red; Ralph Curtis, creamy white; Carrie, golden-yellow; Goacher's Crimson, rich crimson; Horace Martin, yellow; Mdme C. Perriere, pink; Normandie, pink; Perle Chatillonaise, salmon-pink; Polly, orange; Roi des Blancs, white; and Nina Blick, red.

NAMES OF PLANTS.

W. J. G., Exmouth.—Cardamine hirsuta.

F. L. S., Wokingham.—1, Saxifraga sancta; 2, Anemone hepatica; 3, Cornus mas.

T. I., Byfleet.—Flowers were very much faded and bruised when received. 1 and 2 appear to be Cattleya Percivaliana; 3, Dendrobium speciosum.

F. J. W., Tavistock.—1, Cyclamen Coum; 2, Saxifraga apiculata; 3, Rhododendron præcox; 4, Iris reticulata.

FORTHCOMING ENGAGEMENTS.

TUESDAY, March 7.—Scottish Horticultural Association meets.

National Amateur Gardeners' Association; meeting at Winchester House, 7 p.m.

THURSDAY, March 9.—National Horticultural Society of France, Exhibition at Paris.

MONDAY, March 13.—United Horticultural Benefit and Provident Society, Annual Meeting at Royal Horticultural Hall, Westminster, at 8 p.m.

TUESDAY, March 14.—Royal Horticultural Society: Committees meet at 12 o'clock; lecture at 3 o'clock on "The Origin of Varieties," by Mr. G. F. Scott Elliott; Scientific Committee at 4 o'clock. An exhibition of forced bulbs will be held on this occasion and continued on Wednesday.

SCHEDULES RECEIVED.

PERPETUAL FLOWERING CARNATION SOCIETY.—Exhibitions will be held at the Royal Botanic Society's Gardens on May 2 and 3, and on December 5 and 6.

NATIONAL DAHLIA SOCIETY.—Crystal Palace on September 7 and 8; and at the Royal Botanic Society's Gardens on September 20 and 21.

PERTHSHIRE SWEET PEA SOCIETY.—A schedule of twenty-nine sweet pea classes. Exhibition at New City Hall, Perth, on August 4 and 5.

OBITUARY.

◆

COL. R. H. BEDDOME.

In his 81st year there passed away, at the end of last week, a famous botanist, Colonel R. H. Beddome. After joining the Army Colonel Beddome went out to Madras, and in 1856 was appointed Quartermaster and Interpreter to the 42nd Infantry Regiment. In early life he took a keen interest in Nature study, and during his earlier years in India he paid great attention to the subject of forestry, so much so that, when efforts were made to save the forests of Southern India, and a department was formed, he was appointed chief assistant to Dr. Cleghorn. In this work he found very congenial occupation, and in 1860 he became head of the Forestry Department, continuing in that office until his retirement in 1882. Considered from a botanical point of view, his books brought him considerable fame; his most notable works are "The Flora Sylvatica of the Madras Presidency," and "The Ferns of Southern India." In the Icones Plantarum there are about 300 plates and descriptions of new and rare plants found by him in the jungles of Southern India. For a long number of years Colonel Beddome was a regular correspondent with Kew, and since his retirement, and residence at Sispara, West Hill, Putney, he was a regular attendant and worker at the Kew Herbarium. His death was sudden, and few people who knew him as a frequenter of Kew and the Royal Horticultural Society's meetings imagined he had reached three score years and ten.

MR. THOMAS THYNE.

At the age of 75 the oldest Dundee seedsman, Mr. Thomas Thyne, passed away after a brief illness. In the presence of a few invited friends his remains were laid to rest in Barnhill Cemetery on February 18. His career as a seedsman began when as a boy, in 1849, he entered the services of Messrs. John Stewart and Sons. By dint of unrelenting perseverance and a keen grasp of business he rose rapidly in the ranks until he gained a partnership, and for about forty years he controlled the big business. In 1886, along with his life-long comrade, Mr. George Paton, who also held a responsible position in the Stewart firm, he started the business of Messrs. Thyne and Paton, which quickly became a household word with amateurs and gardeners far and near.

The partners and comrades of earlier years worked like Trojans, building up a splendid business, and when family affairs demanded a separate business and estate, by mutual consent the old name was dropped, and new ones substituted four years ago. The deceased, along with his son, Mr. James Thyne, already a partner under the old name, starting under the name of Messrs. Thyne and Son in the old premises, while Mr. Paton elected to remove to another site, and there, along with his son (trained in the business, too), began under the new title of Messrs. George Paton and Son.

The deceased gentleman was held in high esteem by those who knew him intimately, and beneath a retiring and reserved disposition there was a kindly, sympathetic nature and unassuming courtesy of manner which endeared him to those who knew him best. He had little to say, but he spoke with judgment and weight.

Dahlia Conference. — The National Dahlia Society has arranged to hold a conference on dahlias and their cultivation at "Carr's" Restaurant, Strand, London, on Friday, the 17th inst. The proceedings will commence at 6 p.m., and all who are interested in dahlias are invited to attend.

THE LANGUAGE OF FLOWERS
"Feed us, we pray you, with
CLAY'S FERTILIZER
and our rare beauty and fragrance will repay you."

CLAY'S LONDON FERTILIZER
TRADE MARK.

It is SAFE, CERTAIN, QUICK-ACTING and ECONOMICAL.
Flowers Grown with CLAY'S FERTILIZER catch the Judge's eye.
Sold everywhere in **6d.** and **1/- Tins**; and **in Branded and Sealed Bags**:—7 lbs., **2/6**; 14 lbs., **4/6**; 28 lbs., **7/6**; 56 lbs., **12/6**; 112 lbs., **20s.** Or direct from the Works, Carriage Paid in the United Kingdom for Cash with Order (except **6d. Tins**).
EVERY GENUINE TIN, BAG, AND SEAL BEARS THE TRADE MARK AS AT SIDE.
CLAY'S SUCCESSFUL GARDENING.—A thoroughly comprehensive, informing, up-to-date Publication. 276 pages, illustrated, bound in cloth. To be obtained of Seedsmen, etc., NINEPENCE NET, or Free by Post for this amount direct from the Publishers as under:
CLAY & SON, Manure Manufacturers and Bone Crushers, **Stratford, London, E.**

CATALOGUES RECEIVED.

G. S. EVANS, BEXLEY HEATH, KENT.—A small illustrated catalogue of Perpetual and Malmaison carnations, concluding with a priced list of a selection of border carnations.

MANSELL AND HATCHER, LIM., RAWDON, LEEDS.—This firm issues a special catalogue of lily bulbs by way of special offer. Besides auratum and speciosum varieties, the beautiful L. sulphureum and L. nepalense are listed, as well as L. longiflorum varieties, L. Henryi, etc.

J. BURRELL AND CO., HOWE HOUSE NURSERIES, CAMBRIDGE.—The list of new cactus dahlias now issued contains descriptions of six show cactus, and two garden cactus varieties, all seedlings raised at Cambridge; the two latter have been certificated by the National Dahlia Society.

JOHN FORBES, LIM., BUCCLEUCH NURSERIES, HAWICK.—A wonderfully comprehensive plant catalogue, very largely devoted to florists' varieties of hardy flowers, such as pentstemons, phloxes, pansies, violas, early chrysanthemums, pæonies, iris, etc.

W. W. JOHNSON AND SON, LTD., BOSTON, LINCS.—The retail seed list from this firm is before us. It includes a number of new culinary and sweet peas and other vegetable and flower novelties in addition to standard varieties.

VILMORIN-ANDRIEUX AND CO., QUAI DE LA MEGISSERIE, PARIS.—Two small but closely printed lists reach us from Paris; one is devoted to chrysanthemums and the other to dahlias and cannas.

R. WALLACE AND CO., KILNFIELD GARDENS, COLCHESTER.—A thoroughly interesting, descriptive, and useful catalogue of bulbs, tubers, and plants for spring planting. Hardy orchids and the new montbretias are deservedly dealt with at some length.

BARR AND SONS, KING STREET, COVENT GARDEN, W.C.—This new catalogue tells of the approach of spring, and reminds us that the time is almost here for planting gladioli; while liliums, dahlias, early chrysanthemums, montbretias, must all be considered for this season's display.

[illegible] W. CROSS, OLD GRAMMAR SCHOOL, WISBECH.—A very comprehensive list of garden and farm seeds. Seed potatoes are a special line, and there is a double white antirrhinum among the flower novelties.

HALLAMS, MOSELEY, BIRMINGHAM.—A closely printed, freely illustrated seed catalogue comes from Moseley, and it is full of interest. Sweet peas occupy a prominent position, but a separate list of these is now published.

W. WOOD AND SON, LIM., WOOD GREEN, LONDON, send us a comprehensive catalogue of horticultural appliances and sundries.

R. H. BATH, LIM., WISBECH.—This firm's spring catalogue is devoted very largely to such popular florists' flowers as dahlias, begonias, pansies, violas, chrysanthemums, and carnations.

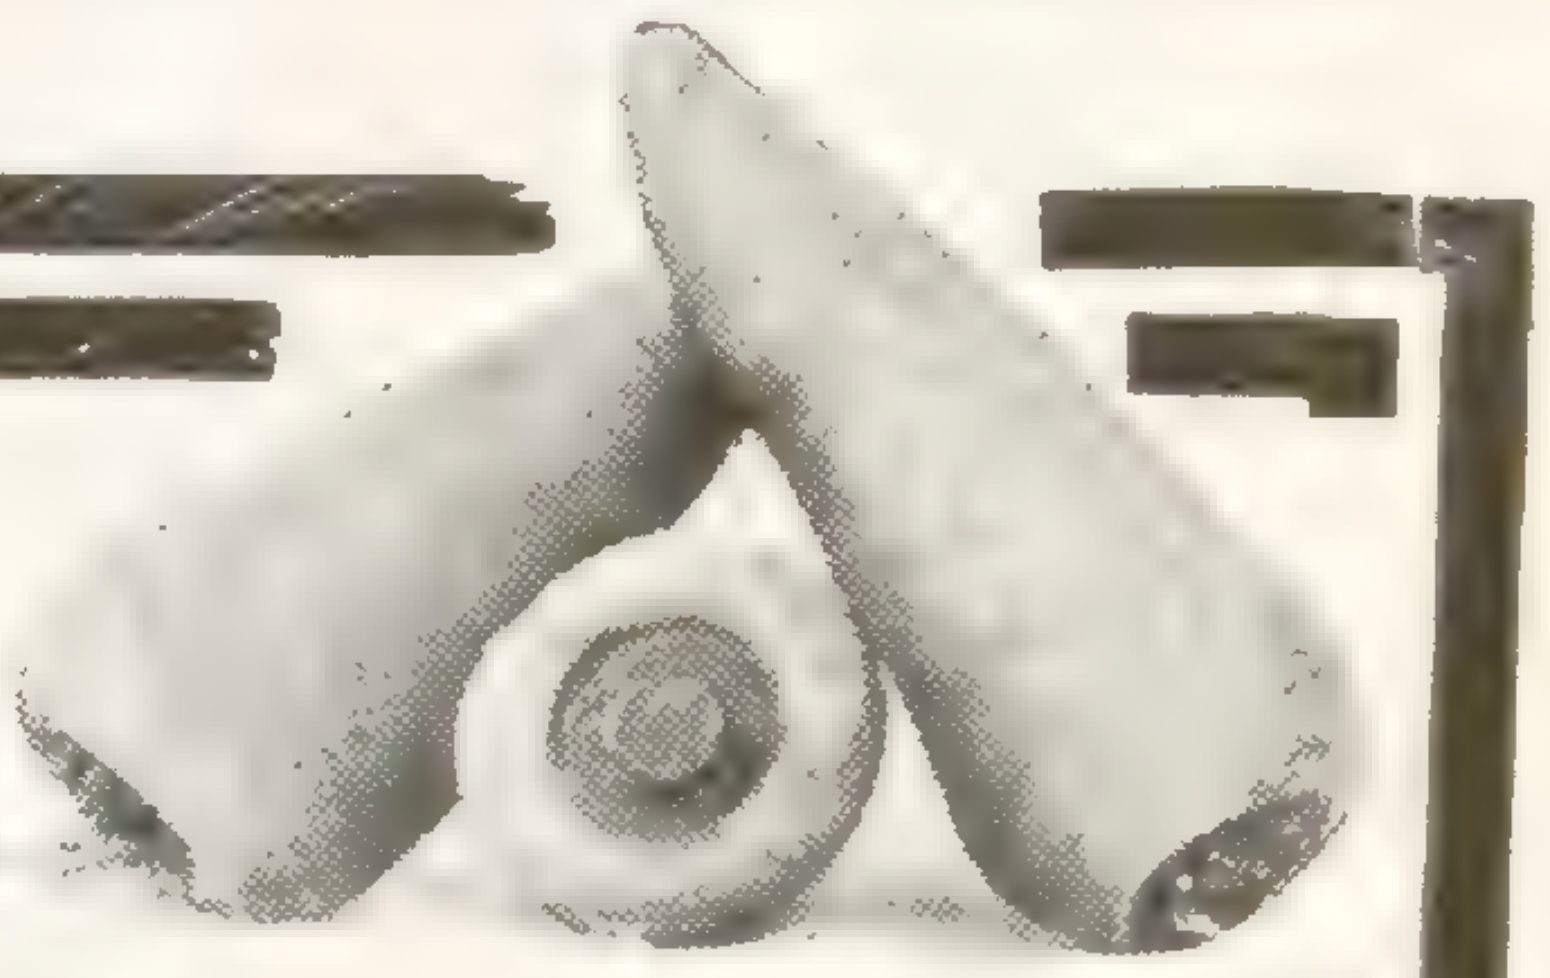
Godfrey, 161; A Tree of Libra Peach, 165; A well-marked strain of French Marigolds, 166; A fine Breadth of Parsley, 167; A splendidly developed specimen of Clematis montana rubens at Kew, 168; [illegible] Larkspurs, 169; One of Messrs. Sutton and Sons' large Primula Houses, 171; The Conservatory at Buxted Park, 173.



Vaporite
The ORIGINAL soil insecticide

USE VAPORITE WHEN DIGGING TO DESTROY SOIL INSECTS

If you dig in 1 lb. of Vaporite to 8 sq. yds. NOW, you will see a great improvement in your plants and vegetables this summer. Soil insects do far more damage than most gardeners really appreciate. Vaporite a non-poisonous powder—can only be applied to the soil when digging before the plants are in. It is sold in tins and casks by all seedsmen. Fuller particulars of Vaporite will be sent post free to anyone filling in this coupon.

CARNATIONS.
"I am quite sure Vaporite was the means of saving my carnations last year, as before using it the bed was full of wireworms."
R.A.S., North Devon.

WIREWORMS, Etc.
"I find Vaporite very effectual. It is the only thing I have found that really destroys wireworms, and I am very glad to have found such a good friend for my garden."
L.E.L., Boscombe.

PRICES—In Tins, **9d.**, **2s.**, **3s.** and **4s. 6d.** (of all seedsmen). In Casks, **7s. 6d.** per ½-cwt. (carr. paid), **11s. 6d.** per cwt. (carr. paid).

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

THE KELWAY "ARTISTIC" BORDER makes a garden of enduring beauty, from early spring to late autumn, with a minimum of cultivation, and without the trouble of constant digging or bedding-out. The plants composing the border are from strong country-grown stocks, which will flourish under almost all conditions. Send dimensions of space to be filled, or write for Kelway's "Gardens of Delight" (6d.). The cost of the "Artistic Border is 15s., or 25s. for 10 square yards

KELWAY and SON, the Royal Horticulturists, LANGPORT, SOMERSET.

NOW IS THE TIME TO PLANT KELWAY DELPHINIUMS which have been improved almost out of recognition in the past twenty years. They produce plants ranging in height from four to eight feet, exceptionally hardy, and with a rich profusion of choice blooms in all the shades of blue.
Choice named varieties: 24s. 34s., and 56s. a dozen.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

EVERY Gardener, amateur or professional, will find a large amount of useful information in the new edition of Kelway's "Manual of Horticulture"—the varieties, prices and culture of all sorts of garden plants, particularly those wonderful improvements raised in the Kelway Nurseries at Langport. A copy will be sent post free for 2s., which will be credited on the first order.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

KELWAY GLADIOLI flower freely in the open air through the autumn. Their fine bold blooms make an admirable addition to borders or beds and are invaluable as cut flowers for church or table decoration. Choice named collections, 3s., 4s. 6d., 6s. 7s. 6d., 9s., 12s., and 18s. a dozen.
Order at once.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

FIDLER'S NEW ILLUSTRATED CATALOGUE OF CHOICE GARDEN SEEDS will be sent, post free, to any address on receipt of postcard. Write at once for a copy. It may help you to save 50% on your seed bill this season. FIDLER and SONS, Royal Berks Seed Stores, Reading.

PRUDENTIAL ASSURANCE COMPANY, LTD.
Chief Office—HOLBORN BARS, LONDON.
INVESTED FUNDS EXCEED £77,000,000.

Summary of the Report presented at the SIXTY-SECOND ANNUAL MEETING, held on 2nd March, 1911.

ORDINARY BRANCH.—The number of policies issued during the year was **80,311**, assuring the sum of **£7,462,496**, and producing a new annual premium income of **£446,473.** The premiums received during the year were **£4,806,121**, being an increase of **£96,014** over the year 1909. The claims of the year amounted to **£3,240,957.** The number of deaths was **8,465**, and **19,157** endowment assurances matured.

The number of policies in force at the end of the year was **903,896.**

INDUSTRIAL BRANCH.—The premiums received during the year were **£7,426,317**, being an increase of **£254,547.** The claims of the year amounted to **£2,805,069**, including **£222,506** bonus additions. The number of claims and surrenders, including **4,600** endowment assurances matured, was **371,023.** The number of free policies granted during the year to those policyholders of five years' standing and upwards, who desired to discontinue their payments, was **145,187**, the number in force being **1,608,935.** The number of free policies which became claims during the year was **42,660.**

The total number of policies in force in this branch at the end of the year was **18,820,427**; their average duration exceeds eleven and three-quarter years.

The assets of the Company, in both branches, as shewn in the balance-sheet, after deducting the amount written off securities, are **£77,529,226**, being an increase of **£3,327,525** over those of 1909.

In the Ordinary Branch a reversionary bonus at the rate of **£1 14s.** per cent. on the original sums assured has again been added to all classes of participating policies issued since the year 1876.

The Directors are pleased to announce an increase in the rate of bonus in the Industrial Branch of the Company as follows:—

All policies of over five years' duration which become claims either by death or maturity of endowment from the 3rd of March, 1911, to the 7th March, 1912, both dates inclusive, will participate. This bonus will be paid by way of addition to the sums assured of:—

£5 per cent. on all policies becoming claims upon which at least five but less than ten years' premiums have been paid,
£10 per cent. on all policies becoming claims upon which at least ten but less than fifteen years' premiums have been paid,
£15 per cent. on all policies becoming claims upon which at least fifteen but less than twenty years' premiums have been paid, and
£20 per cent. on all policies becoming claims upon which at least twenty years' premiums have been paid.

Messrs. Deloitte, Plender, Griffiths, and Co. have examined the securities, and their certificate is appended to the balance-sheets.

THE FINEST HARDY ANNUALS EVER SENT OUT, AND NO COTTAGE, VILLA, OR MANSION SHOULD BE WITHOUT THEM.

They flower on long, stout stems, and are most useful for Table Decoration, Wreath Making, and all Decorative Purposes. Should be sown in the open ground from April to June. These beautiful flowers have been awarded more Gold and Silver Medals than any other Hardy Annual, and the ever increasing demand for the Seeds is a proof of their popularity.

H. S. CAIN, Esq., Sheals Crescent, Maidstone, writes:—"I should like to say I was delighted with the **New Centaureas** I had from you last year, and the good results I had."

Sergt. Drum. LAVINGTON, The Barracks, Reading, writes:—"Please send me a packet of **Centaurea** Seed. Those I had last year growing in my allotment were particularly fine, and lasted in bloom a long time."

NEW ROSES

WM. PAUL & SON, WALTHAM CROSS, Ltd.,

Beg to offer strong plants of the following New Roses raised by them at the Waltham Cross Nurseries :—

Varieties of 1910.

Alice Cory Wright (H.T.), Dwarfs, **7/6** and **10/6** each.
Elsie (Wichuraiana, Rambler), Dwarfs, **7/6** each.
Juliet (Hybrid Briar), Dwarfs, **10/6** each; Standards and Half-Standards, **10/6** each.
Portia (H.T.), Dwarfs, **7/6** each.

Varieties of 1909.

Althea (H.T.), Dwarfs, **3/6** each; **36/-** per dozen.
Cynthia (H.T.), Dwarfs, **3/6** each; **36/-** per dozen; Standards, **5/-** each.
Fairy (Multiflora Rambler), Dwarfs, **2/6** each; **24/-** per dozen.
Margaret (H.T.), Dwarfs, **3/6** each; **36/-** per dozen.

For full descriptions of the above, and for New Roses of other raisers and general collection of Roses, see Rose Catalogue, post free on application.

Pauls' Royal Nurseries and Seed Warehouse,
WALTHAM CROSS, HERTS.

VOL. LIV.—No. 2,993. SATURDAY, MARCH 11, 1911.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

"Rose, Bravest of the Flowers."

Much has of late been said and written about the flowers of the Coronation, and not a few of those who have taken part in the discussion appear to have been under the impression that it was simply necessary to write a letter, anonymously or otherwise, to one of the journals, to ensure some flower being closely associated, to the exclusion of all others, with the great event in June next, which all loyal citizens of the British Empire are anticipating with such keen interest. Several suggestions have been made with regard to the so-called Coronation flower, but they have all been wide of the mark, as might be expected when people are discussing a matter about which they know but little, or have failed to give serious thought to it before proceeding to dogmatise thereon. We have on a goodly number of occasions been asked whether this, that, or the other flower would be selected as the Coronation flower, and whatever the flower about which the enquiry has been made, we have unhesitatingly answered No. Our justification for giving a direct negative to these inquiries is, of course, the fact that there will be no such flower. As a matter of course flowers will be prominent in the functions associated with the Coronation of the King and Queen, and we know that Her Majesty has graciously consented to accept a bouquet from the Gardeners' Company for the ceremony. It may certainly be assumed also that large numbers of those who owe allegiance to King George V. will wear flowers on the day of the Coronation, and there can be no doubt that a considerable proportion will wear the flowers they can the most readily obtain. Hence we shall doubtless see the rose, the carnation, the sweet pea, and it may be the humble but fragrant mignonette with a number of other flowers used for personal adornment in all large assemblies. All the flowers suitable for the purpose may be worn without a violation of good taste; but those whose means place them in a position to exercise a choice in the selection of flowers should undoubtedly give preference to the rose. In selecting the flower which over a thousand years ago a great poet described as the "Rose, bravest of the flowers," they will have the sanction of tradition and good taste. There is no occasion to pass under review the flowers that have been suggested as the "Coronation Flower" for, with the exception of the rose, which has been mentioned by one of our correspondents, they have no claims for pre-eminence, excepting it be their charms of colour and form, and it may be fragrance. The rose possesses all these attributes of beauty in a marked degree; it has also a strong constitution, is profuse in blooming, and in its multiplicity of varieties the flowers evince a remarkable diversity of form and colour and contribute materially to the varied attractions of the garden and hedgerow. The claims of the rose are great if we did nothing more than take into consideration the charms of the cultivated forms in which gardens are now so rich, but the claims of the flower are greatly increased when we consider its close association with the history of the British Isles. For a period long anterior to "the brawl in the Temple Gardens," the rose has been closely associated with one of the most ancient names of England. In a consideration of the etymology of the word Albion, the elder Pliny expressed the opinion that the island may have derived its name from the great abundance of white roses. Whether Pliny was right in his conjecture need not now be discussed; but it is the opinion of the authorities that the White Rose of York was a double form of the field rose, Rosa arvensis, a native species with white flowers, that was then, as now, plentiful in various parts of the country. Long previous to the time of Gerard the double white form of this species was a great favourite in English gardens, and at the time of the Wars of the Roses, which began in 1445, it was undoubtedly as generally cultivated as the Red Damask or Rose of Lancaster, and fully equal to it in significance. This rose was not, however, confined to gardens, if we may trust this old author, for in his "Herbal" he writes: "The double white rose doth grow wilde in many hedges of Lancashire in great abundance, even as briers do with us in these southernly parts, especially in a place of the country called Leyland, and in a place called Roughford, not far from Lathom." The story of the Wars of the Roses as told by Shakespeare is well known, and all that concerns us now is the fact that the feud between the great Houses of York and Lancaster were brought to a close in 1485 by the marriage of Henry VII. with Elizabeth of York, and that the Tudor sovereigns adopted as their badge a red and white rose as a symbol of the union of the two rival Houses. From that distant period until the present time the rose has had a place in the Royal Arms of England, and it has also been fully acknowledged as the floral emblem of the country. Therefore, after a full consideration of the facts, it might with full justification be asked what more fitting flower could be named for close association with the Coronation and its festivities in June next? We might well write with reference to the special claim of the rose for prominence in this connection as did Gerard with regard to the place of the flower in the garden, for no words could be more appropriate in relation thereto than those of this old author: "The Rose doth deserve the cheefest and most principall place among all flowers whatsoever, being not only

MR. W. F. COOLING.

esteemed for his beautie, virtues, and his fragrant and odoriferous smell, but also because it is the honore and ornament of our English Sceptre."

Mr. W. F. Cooling, of the firm of Messrs. George Cooling and Son, Bath, occupies a high position in the world of horticulture, and is especially notable as a rosarian. Mr. Cooling is a strong advocate of garden roses, and especially favours the free-flowering hybrid tea varieties in this connection. He has also devoted considerable attention to climbing roses, and in rose circles he is regarded as one of the leading authorities on them. Mr. Cooling is a regular and successful exhibitor of roses, and as a raiser he is best known for his work among Bourbon varieties, his variety named Purity being one of his great successes, and cne that received the National Rose Society's gold medal as far back as 1898. He is an excellent companion, and his genial good humour has often served to smooth over difficulties such as sometimes arise over a heated discussion. Mr. Cooling takes an active interest in the affairs of the Gardeners' Association in his native town, and also in the management of the National Rose Society, being a member of the Council and of the Publication Committee of the last-named society. As a member of the Council of the National Rose Society over a long number of years, Mr. Cooling has served the rose world ably and consistently for a considerable period—a period that all who know him will hope may not be ended for long years to come.

The Origin of Varieties, like the origin of species, is a matter of immense interest, and any new information cannot fail to be of great value to horticulturists, especially when we remember how much we depend upon varieties, rather than on species, for farm and garden crops, and for the decoration of garden and greenhouse. Mr. G. F. Scott-Elliott, M.A., B.Sc., is to give the sixth Masters' Lecture at the Royal Horticultural Hall on March 14, at 3 p.m., and his subject will be "The Origin of Varieties."

February in the North.—February this year, writes our Aberdeen correspondent, has been finer than usual. We have had very little snow or frost. Whether this is a good sign for the rest of the year is more than doubtful, if we are to believe some popular sayings. For example, "If Candlemas day be clear and fair, the half o' the winter's to come and mair." Little importance, however, can be attached to such sayings, for they are about as often wrong as right. For example, in 1868 we had a mild and dry February, yet the following summer was one of the warmest and driest ever experienced. We had the crops all in the cornyard by August 7, a very early finish. Again, in 1878, February was very dry and mild, and July was also fine, warm, and dry. In many other years also somewhat similar weather has occurred. In 1899, for instance, February was quiet and dry, with little snow but much frost, and the grain crop of that year was about the most productive ever reaped. For quality, that of 1898 excelled it, and nearly came up to it in quantity, but February in 1898 was stormy at times, although there was no heavy snow. The amount of rain and melted snow this year in February was 2.13 inches, which is just about the average quantity for that month during the last 40 years—the largest being 4.39 in February, 1876, and the smallest 0.35 in February 1891. As regards temperature, the average of the 43 years from 1867 to 1909 inclusive for February, as recorded at Aberdeen, is 38.32 degrees, the highest being 43.2 degrees in February, 1882, and the lowest (decidedly) 29.4 degrees in February, 1895, in which year July was fine and mild. Owing to the absence of any severe frost, turnips have been scarcely at all injured, and as they are rather an extra fine crop, they are more plentiful than usual at this season of the year, so that sheep farmers are getting them on easier terms than they generally do.

Conference on Dahlias.—As briefly announced in our issue of the 4th inst., a conference on dahlias will be held by the National Dahlia Society, at Carr's Restaurant, Strand, London, on Friday next, the 17th inst. Mr. Edward Mawley, V.M.H., president of the society, will occupy the chair, and will open the proceedings with a short address on Pompon Dahlias. Mr. Joseph Cheal will read a paper on the Cultivation and Usefulness of Single Dahlias, to which he has devoted much attention for some years past, and Mr. George Gordon, V.M.H., chairman of committee, will contribute a paper on Decorative Dahlias, with special reference to an early and abundant production of flowers. The conference will commence at 6 p.m., and all who are interested in dahlias, whether members of the society or not, are invited. There will be no charge for admission.

Gardeners' Company's Visit to Holland.—The Master and Wardens of the Worshipful Company of Gardeners, together with some members of the Court of the Company, propose to inspect the leading bulb farms of Holland from April 27 to May 1 of the present year.

Lawn Rolling on a Sunday.—At Chertsey, an employer recently gave his head gardener, through the housekeeper, an order to roll the tennis court on a Sunday morning; it appears that the order included the due preparation of the court on the Saturday, the previous day. The lawn was made ready on the Saturday, but the gardener refused to roll it on the Sunday, urging that this part of the order was unreasonable. The employer gave the gardener a fortnight's notice to leave, but the latter required a month's notice, or wages in lieu thereof. This was refused, and so the action of Reeves v. McLaren was heard before Judge Harrington at Chertsey, recently. His Honour gave judgment in favour of the gardener, Mr. T. Reeves, and observed that refusal to perform unnecessary work on Sunday could not be taken as an excuse for instant dismissal, therefore plaintiff was entitled to a month's wages.

Horticultural Club.—The next house dinner of the club will take place on Tuesday next, the 14th inst., at 6 p.m., at the Hotel Windsor, Victoria Street, S.W. Mr. A. D. Cotton (of the Herbarium, Royal Gardens, Kew), will give a lecture on "Fungi," and his lecture will be illustrated by lantern slides.

Presentation to Mr. F. C. Lawrence. — At a recent meeting of the Winchester Gardeners' Association the lecturer for the evening was Mr. F. C. Lawrence, lecturer in horticulture for the Hants County Council. As Mr. Lawrence is leaving Hants for Northampton occasion was taken of his presence at the Winchester Association to show how greatly his services have been appreciated. At the close of the meeting, Mr. W. H. Roberts, on behalf of the members, presented Mr. Lawrence with a beautiful horn-handled, gold-mounted partridge cane walking stick, the inscription on the massive gold band reading, "To Mr. F. C. Lawrence, from the Winchester Gardeners' Association, Feb. 21, 1911."

A New Genus of Orchids.—So great are the advances made in the hybridisation of orchids that new generic titles have to be created occasionally for use in the case of bigeneric or multigeneric hybrids. Odontioda, for hybrids between odontoglossum and cochlioda, we are all quite familiar with, and miltonioda, for hybrids between miltonia and cochlioda has been referred to on several occasions in these columns; but oncidioda is more recent and embraces hybrids between oncidium and cochlioda, while Vuylstekeara is the new and commemorative title now given to hybrids between miltonia and odontioda, and it will embrace all hybrids in which miltonia, odontoglossum, and cochlioda are concerned.

Presentation to Mr. R. M. Worden.—On the occasion of a recent meeting of the Chelmsford Gardeners' Association, held at the County Laboratories, Mr. R. M. Worden, who has proved an extremely capable secretary to the association, was presented with two very sensible presents, i.e., a handsome umbrella and a fine fountain pen—the former to guard him against storms, the latter suggestive of further service. At this meeting, Mr. Andrew Ireland, of Marks Tey, gave a lecture on "Vegetables," and there was an excellent display of forced bulbs.

Edgeworthia chrysantha at Leonardslee.—This interesting and rare shrub, from China and Japan, is generally described as a greenhouse plant, but under favourable conditions it not only survives, but flowers freely out of doors. In Sir Edmund Loder's garden at Leonardslee, Horsham, a specimen planted against a south wall is about three feet high, and is at present carrying a terminal cluster of flowers on almost every shoot. The flowers are small, somewhat like those of the daphne, yellow, and deliciously scented, Mr. W. A. Cook has kindly sent us one of the fragrant clusters. Grown in a greenhouse Edgeworthia chrysantha is said to be evergreen, but out of doors at Leonardslee it is deciduous.

The Codlin Moth (Carpocapsa pomonella) is one of the most destructive of the injurious insects with which the Canadian fruit growers have to contend, and causes, it is estimated, an annual loss in Ontario of about 2,000,000 dollars (one dollar equals 4s. 2d.). Strenuous efforts are being made by the Ontario Department of Agriculture to assist fruit growers in combating the moth, and the bulletin that has been prepared by Professor L. Cæsar, of the Department of Biology, should be a substantial help. Full information is given as to the life history of the Codlin moth, the methods of spraying, spraying machines, and the preparation of spray fluids. The information is throughout remarkable for its fulness of detail, and as it is based on work in the fruit plantations it is trustworthy. We have no knowledge of an English publication containing similar information.

Honour to Mr. Jackson T. Dawson.—Mr. Jackson T. Dawson, who has been associated with the fortunes of the Arnold Arboretum from before the régime of Prof. Sargent, and who has had so much to do with the practical side of affairs, was awarded the George Robert White gold medal a short time since by the Massachusetts Horticultural Society. The society honoured itself by honouring such a splendid worker in horticulture as

Jackson Dawson. The latter is of English birth, but has been in America since his boyhood.

Starlings in Orchards.—In a letter which appeared in a recent issue of the "Times," Mr. T. G. Rogers, of Simkins, Heathfield, Essex, strongly condemns the starling for its destructiveness in orchards and gardens. He writes: "My experience in West Essex, where I have resided thirty years, demonstrates that the starling has a record as a depredator of orchards second to no bird I have observed. I have, in the neighbourhood of Loughton, an orchard of choice pear, apple, plum, and greengage trees. The damage done by starlings, had I not watched and seen, I should have disbelieved. No artificial methods, such as scarecrows, kept these birds away. . . . The damage was worse than the destruction—that is of fruit eaten." We can fully confirm Mr. Rogers with regard to the damage starlings are capable of doing in orchards, and agree with him that their numbers should be kept within reasonable limits. Not only will starlings do much damage in orchards, but they will crowd into gardens during the fruit season and do serious injury to the crop. Last summer we had our attention called to several apple trees bearing good crops that had the principal part of the fruit damaged by these birds. In some districts blackbirds are hardly less destructive to apples when nearly full grown, and they show a nice discrimination in the selection of varieties. They invariably select the best-flavoured varieties of apples first, and when supplies of these are cut off they take the next best, and so on. Appreciating the importance of birds in the economy of Nature, and also their manifold uses, we are strongly opposed to their wholesale destruction, but those kinds known to be capable of inflicting heavy losses to cultivators should have such limitation imposed upon their rate of increase as to prevent excessive multiplication.

The North of England Horticultural Society will hold its first meeting, exhibition, and lecture in the Emmanuel Hall, Leeds, near the University, on Wednesday, March 22. The several committees will meet at 11 a.m., and the Council at 12 o'clock; the show will open at 1 o'clock, and the lecture begin at 6.30 p.m. The lecturer on this occasion is Dr. Russell, of Rothamsted, and his subject is "Soil Sterilisation." The council has decided to grant medals according to merit to the exhibits; the gold-medal standard is to be equal to that of the Royal Horticultural Society. There are to be both large and small medals in gold, silver-gilt, silver and bronze, and for novelties there will be three grades of the Northern Diploma, i.e. Mark I., Mark II., and Mark III. The society will issue a monthly magazine, and hopes to send out the first number soon after the meeting of March 22; in addition to reports of the society's meetings, lectures, etc., the magazine will contain monthly reviews of all weekly horticultural papers.

A Garden for the B.G.A.—A brisk discussion has been carried on for some time in the "Journal" of the British Gardeners' Association concerning the advisability or otherwise of starting a large association garden. The suggestions for the conduct of such a garden have been many and various, but one of the best is that from Mr. Alex. Dean, V.M.H., who writes: Obviously there is no room whatever to create a nursery garden as that special part of horticultural work is far too crowded now. Still further, to enter into competition with the nursery and seed trade would be to kill much of the best support the B.G.A. now secures. Assuming the primary object of a garden to be to provide out of work members with employment, which of course is good, and still further to conduct it on the best practical market lines that it may be to all who work in it a great instructor, and that is good also; then the only course is to embark in purely market work, allied with intensive culture so far as that can be made profitable. But to start a garden of this kind with any prospect of success not less than £5,000 capital would be needed. That needs some getting. Even then how much success would have to depend on really capable management.

AMONG THE ROSES.

Looking at our roses at the end of February, I am agreeably surprised at the way they have come through the winter so far. The majority of buds upon both dwarf and standards look plump and promising. The varied way in which these come through the winter is often surprising. During a wet winter we find buds upon dwarf stocks do not escape so freely as those upon standard briars, while a very dry and cold winter seems to have more effect upon standards. It is the same in my experience whether they are budded stocks of the previous season or established plants, a dry and keen wind doing more harm to standards than dwarfs when accompanied by frost.

I was gratified to find the bulk of the rose wood that I tried the knife upon looking so sound, and the pith clear. Of course, there are, as usual, some varieties more affected than others, our worst being Enchantress and Mrs. Edward Mawley, two grand roses that have frequently disappointed me in their winter behaviour. Others more affected than the majority are Alfred K. Williams, Lady Moyra Beauclerc, Bridesmaid, Perle des Jardins, Ernest Metz, Innocente Pirola, Liberty (always dying back with us), and Comtesse de Nadaillac.

I am surprised to find the frost has cut Madame Abel Chatenay so much, especially upon the standards. On the other hand, George C. Waud is sound, which was far from the case last spring. Claire Jacquier and Climbing Perle des Jardins are rather hard hit, but these are always tender here; American Pillar still carries its foliage, and is, I think, the most nearly an evergreen rose we have at present, and almost worth growing as a hedge for that reason, especially as it gives a beautiful summer and autumn display, followed by deep scarlet hips.

Roses grafted as advised in the issue of the Gardeners' Magazine for November 5 of last year are looking very well, and the most forward have been put into larger pots. Of course, grafting has been more or less continuous up to quite recently, and although those worked early, and now taken out of the case to harden, will enjoy a little sun, much sun should not reach the younger plants for a time, especially towards midday. A gentle syringing helps them much, but should never be given until the plants are out of the case. We leave our last batch in the cases, removing the glass entirely, which is practically the same thing as taking them out. The bulk of the plants will want potting as opportunities occur and the plants progress. I do not like to have roses root bound in such a tiny space, and so shift them on sooner than most folks, believing in a much freer run for the young roots than can possibly be the case otherwise.

Rosarian.

R.H.S. EXAMINATION OF EMPLOYEES IN PUBLIC PARKS.

The following report of this examination has been issued:

The Royal Horticultural Society's sixth examination of employees in public parks was held on January 16, 1911.

As previously, the examination was partly vivâ voce and partly written, occupying three hours and twenty minutes. It was held at the society's hall in Vincent Square, Westminster.

Sixty-eight candidates entered, and of these 16 secured places in the first class, 31 in the second, and 15 in the third, leaving five candidates who failed to satisfy the minimum requirements of the examiners, and one who was absent. The majority of the London parks employees have now obtained passes in this examination, hence the smaller number of the entrances this year.

It is hoped to organise another examination in 1912, not only in Westminster, but in some of the most central towns of the provinces, and the secretary of the society would be glad to hear as early as possible from those public authorities who would like their gardeners to sit for it.

The written papers show this year a greater familiarity with trees and shrubs than formerly. The more general use of the botanical names and terms was most gratifying, indicating as true what has for so long been contended, viz., that it is equally easy to learn and remember the botanical name if its origin and meaning is understood.

Question 3 revealed a very great lack of knowledge of the more recently improved varieties of lilac, spiræa, deutzia, and philadelphus, and coupling this fact with the frequent excuse of candidates that, being stationed in one park only, they have no facility for extending their knowledge, public park gardeners are urged to take every possible opportunity of visiting other public and private gardens, and of studying closely the weekly gardening periodicals. It may even be possible—and it is certainly very desirable—for the local authorities to cause men, who are anxious to extend their knowledge and experience, to work for definite terms of, say, three months in different gardens, according to an arranged cycle. The stimulus of the sight of the new plants and shrubs, and conditions of environment of the varied gardens, added to the encouragement such a procedure would give, must have highly beneficial results.

The questions on manures were fairly well answered, but their nature, and the principles underlying the use of each, are insufficiently understood. Something more definite than the mere mention of a name is wanted. The different characteristics of different manures; their particular and specific uses; their origin and composition; the most practical methods and best times of applying them to the soil, and their relative cost, should be familiarised.

Question 12 was set to test candidates' powers of observation, and to enable them to describe the habits of tree life that come under their notice every day; but the answers were disappointing—even the term "habit of growth" being, in some cases, either not known or not understood. Gardeners must learn the art of seeing, that is of observing, if they would be something more than mere rule-of-thumb tillers of the ground. Again, some candidates confused evergreens, firs, and pines with decidous trees when they were asked to illustrate the latter by common examples.

Most of the examples in freehand drawing of sketches of flower-beds were very poor in execution, and greatly lacking in fertility of thought and ideas. The need for the sense of design has been frequently urged in the reports of previous examinations.

The arithmetic in Questions 13 and 14 was simply deplorable; indeed, in the latter, no two answers agreed!

Candidates are strongly recommended to take the list of questions set on January 16, and work them out at home with the aid of their text-books, committing well to memory facts unknown to them. The object of the examiners, remember, is not to find fault, but to help the candidates to discover their own deficiencies, and to suggest how they may best supply them.

In the vivâ voce questions the candidates on the whole acquitted themselves very well. The questions asked are entirely confined to those matters of which a knowledge is absolutely indispensable to the successful working and management of public parks and town gardens. They are mostly of a simple and practical character, so that any observant worker with a few years' experience behind him should have no difficulty in answering them quite satisfactorily. The candidates were particularly weak on the point of identifying trees and shrubs from specimen twigs—although each specimen represented widely divergent "habits of growth," and quite distinctive features assisting recognition.

So many gardeners having now successfully passed this parks examination, the secretary of the Royal Horticultural Society recommends to them the higher "general examination," which is held annually in April. Do any gardeners regret their successes in the parks employees examination? Has not the result to themselves, mentally, intellectually, and practically, proved fully, and more than fully, "worth the while"? worth the time and effort devoted to secure a pass—not so much as a step to promotion in wages, but rather for the pleasure and happiness resulting from a better understanding of the subjects of their daily care.

Surely the answer cannot be anything but "Yes"; and, therefore, they are asked not to be contented with the progress which they have thus far achieved, but to press on to higher ability and honours, and to that greater knowledge which success in the "General examination" implies.

At the same time it is hoped that all candidates low in the list will not be disheartened, but encouraged, by the greater success of their fellows to work on to higher places next year. With so encouraging a report as only five actual failures there is every hope for those who have only won a third class to work up to the second, and the seconds up to the first class. And with patient endeavour and careful observation, coupled with intelligent inquiry into the reasons and causes for what is done and observed during the coming season, much progress should be made and useful knowledge stored up in readiness not only for the next examination, in January, 1912, but to be put into practice during the whole life's work.

It should perhaps be put on record that there is absolutely no difference of merit whatsoever in being placed in Division A or in Division B. A first class in one is as good as a first class in the other. The two divisions are only kept up for the convenience of certain public authorities.

C. R. Fielder,
Owen Thomas,
John W. Odell,
W. Crump,
Edward White,
E. Beckett,
W. Wilks.
Examiners.

DIVISION A.—Class I.

1. W. H. Thomas, Wandsworth Common.
2. Stephen Watson, Lewisham.
3. J. Hurley, Deptford.

Class II.

1. G. Hodsdon, Brockley.
2. J. Chapman, Brockley.

DIVISION B.—Class I.

1. H. W. Hotten, South Hackney.
2. E. C. Moody, Kennington Park.
3. A. Chipperfield, Rotherhithe.
4. E. A. Duley, Cardiff.
5. R. A. Dummer, Kew.
6. J. Wigg, East Dulwich.
7. G. Baker, South Tottenham.
8. W. H. Radley, Mount Pleasant Lane, N.E.
9. H. Spashett, Battersea.
10. C. E. Lewis, Lewisham.
11. E. Saunders, Sunbury.
12. E. W. Vince, Hither Green, S.E.
13. Ernest Hickford, Highgate Hill.

Class II.

1. C. H. Harris, Kew, and W. G. Knight, East Ham.
3. W. M. Salway, Highgate.
4. R. F. Maythorn, South Hackney.
5. R. Smith, Stoke Newington.
6. F. Longmire, Clapham Common, and E. Staples, Charlton.
8. J. Jepps, Upper Holloway, N.
9. A. Morley, Hackney.
10. H. E. Mitchell, Brixton.
11. C. A. Turner, Enfield.
12. P. J. Thomas, South Hackney.
13. G. Hill, Dulwich; W. J. C. Kemp, East Dulwich; and F. Williams, Lambeth.
16. A. H. J. White, Richmond.
17. G. T. Joiner, South Tottenham, N.
18. W. Power, Victoria Park, N.E.
19. W. Atkey, Finsbury Park, N.
20. A. E. Baggs, Kew, and W. H. Ricketts, Forest Hill.
22. F. C. Love, Merton, and R. W. Boyle, Streatham.
24. R. T. Pike, Camberwell.
25. J. Crombie, Chelsea, and J. Pepper, Battersea.
27. G. T. Wiltshire, Homerton, and W. Good, St. Albans.
29. C. R. Y. Peck, Rotherhithe.

CHARD NURSERIES.

Frequenters of the leading flower shows in various parts of England are familiar with the extremely beautiful centaureas, or sweet sultans, so well grown and extensively shown by Messrs. Jarman and Co., The Nurseries, Chard, Somerset. Often, too, this firm also exhibits zonal pelargoniums, border and perpetual carnations, roses, and hardy perennials, whilst the daintily pretty sweet pea Mrs. Townsend has, during the past season or two, won its way to the hearts of lovers of sweet peas. It was, therefore, full of expectation of finding an establishment of general interest and great excellence that I travelled to the quiet but flourishing town of Chard, towards the end of last summer, on a visit to the nurseries from which so many fine exhibits had been sent to the shows, and it is pleasant to record that my expectations were fully realised.

It was a glorious day, one of the few that merited such adjective during the summer of 1910, and the thought continually recurred to my mind that the employees in these nurseries, situated in so beautiful and peaceful a spot, enjoyed a life far more pleasant than that of the London worker, or, for the matter of that, any City man. It must certainly be a pleasure to grow nursery stock at Chard, the soil, as well as the situation and climate, being most favourable to high development.

The home nursery had scarcely been entered when long rows of sweet pea Mrs. Townsend, some distance away, arrested attention. They were very conspicuous by reason of the fact that the plants had attained a height of nine feet or more, and stood head and shoulders above the other varieties. Before coming to the sweet peas, however, I was attracted by a great "break" of standard apple trees, that were four years old, and certainly one of the finest and most useful breadths of trees it has been my pleasure to see on any nursery. They included excellent trees of Cox's Orange, King of Pippins, Peasgood's Nonsuch, and many other of the finest dessert and culinary varieties. A plan adopted here, and with evident success, is to mulch the ground between the rows with loose branches of furze, etc., the result being that the top soil remains moist during summer, and the roots of the trees are kept quite close to the surface. Trained fruit trees are also a feature, plums, pears, and apples all being exceptionally well grown.

Conifers in variety, and ornamental shrubs of varying character, occupy a considerable area, and the different shades of green afford a pleasing contrast to the blaze of brilliant colours in the great collection of dahlias growing near by. No useful purpose would be served by enumerating the varieties of these and other popular florists' flowers that are grown at Chard; it is sufficient to say that the collections are representative of the best of both standard and new varieties in the several sections. On either side of the main entrance show borders were making a bold display at the time of my visit, with brilliant salvias, golden calceolarias, violas, and other suitable subjects, the valuable Wichuraiana rose Dorothy Perkins, growing vigorously and blooming profusely in the background, and producing a delightful display of colour.

Naturally, I was anxious to see the renowned sweet sultans growing "at home," and the long beds were wondrously attractive. The amount of bloom each plant produces in the course of the season must be prodigious, for, notwithstanding the fact that immense quantities of flowers used at the shows at which Messrs. Jarman and Co. had exhibited had been cut from the same beds, there were, at the time of my visit, shoals of the lovely blossoms in each of the varieties, and any amount of buds still to open.

In the range of glass-houses zonal pelargoniums were the leading feature, but there were also fine batches of Marechal Niel, W. A. Richardson, and other roses in pots, perpetual carnations, and double white primulas also being largely grown. Messrs. Jarman and Co. do a large trade in floral designs, and such useful subjects as stephanotis, Niphetos rose, chrysanthemums, and other subjects of value for the supply of cut flowers are largely grown. In an ingeniously constructed orchard house were heavily laden trees of Coronation and Lady Sudeley apples, with trained peaches at the back.

At the Devonia Nursery, situated some distance from the town, on a hill 600 feet above sea level, the bulk of the roses are grown, and healthy vigorous plants they were; Lyon Rose, Dean Hole, Frau Karl Druschki, and, in fact, the best varieties of all classes, are grown, those which have attained foremost positions, either as exhibition or garden roses, being most in evidence. Rhea Reid has done exceptionally well at Chard, and Betty is also very free.

Gooseberries and currants, especially the black variety Boskoop Giant, are largely and well grown, and of privet tremendous quantities are annually propagated to keep pace with the constantly increasing demand for this useful hedging plant.

Rest and refreshment at the residence of Mr. Townsend, the genial head of the firm, were very welcome after the tour of the two nurseries, and time sped rapidly as we chatted over the many successes of the firm, and the writer learned of the extent of the great seed business that is an important branch of this very comprehensive establishment. The vegetable seed department is, it need hardly be said, thoroughly up-to-date, and the operations of the farm seed department are of an extensive character.

Visitor.

Pink-flowered Freesias.—Since the advent of Freesia Armstrongi, with blossoms of a rosy-lavender tint, we have had several hybrids raised between this and some of the other kinds. In some the flowers are more or less pink, while rose-lilac and lavender tints also occur amongst them. None of these are the equal of F. refracta in fragrance, but they are not quite scentless. They are very pretty, in some cases quite delicately tinted, and afford a pleasing variety from the whites and yellows which go to make up the better-known forms of freesia. Varieties showing the influence of F. Arsmtrongi are Dainty Maid, silvery-pink with a golden centre; Rose Queen, carmine rose; Tubergeni, rose-lilac, light throat; and Amethyst, soft mauve, marked in the throat with yellow.—W. T.

ROCK GARDEN PLANTS FROM SEED.

To maintain a rockery in a well-furnished condition it is always necessary to have a good stock of plants at hand to replace failures and fill up blank spaces, which are bound to occur. Our climate, although very conducive to the growth of the majority of plants suitable for the rock garden during spring, summer, and early autumn, is too damp through the winter and late autumn, consequently many choice subjects succumb to the unnatural conditions.

There are two ways of raising and maintaining a supply, one from seed, the other from cuttings. Of course, when one wants a true stock of any particular variety in most cases it is necessary to propagate by cuttings, which, with many plants, is a very difficult matter. There are, however, large numbers easily grown from seeds, and if sown in April, and carefully attended to, will make good flowering plants for putting out the following spring. All the dianthus family are easy to cultivate, and some beautiful varieties are often obtained, especially of the superbus and sylvestris types. Campanulas, again, lend themselves wonderfully well to this method of propagation, notably C. carpatica, C. fragilis, C. barbata, C. rhomboidalis, C. pusilla, C. muralis, C. pulla, and C. turbinata.

Leontopodium alpinum, the much-sought-after edelweiss, will need two seasons in which to make a good-sized flowering plant, yet it is easily grown from seeds. Aubrietia, erinus, alyssum, arabis, various saxifragas, iberis, cheiranthus, draba, linaria, arenaria, æthionema, œnothera, alpine and Iceland poppies, and many others, can all be easily raised. Some are slower growing than others, and take longer to make suitable material for planting out, but all are of fairly quick germination.

Seeds should be sown in April, in pots, placing them in a cold frame, and covering the pots with paper to prevent too rapid evaporation. When the seedlings are large enough to handle they should be transplanted into boxes, and after they have attained a suitable size be potted. It is much safer to winter them in cold frames, not so much for protection against the frosts, as against wet. Full exposure should be afforded during dry weather, and no coddling must be permitted.

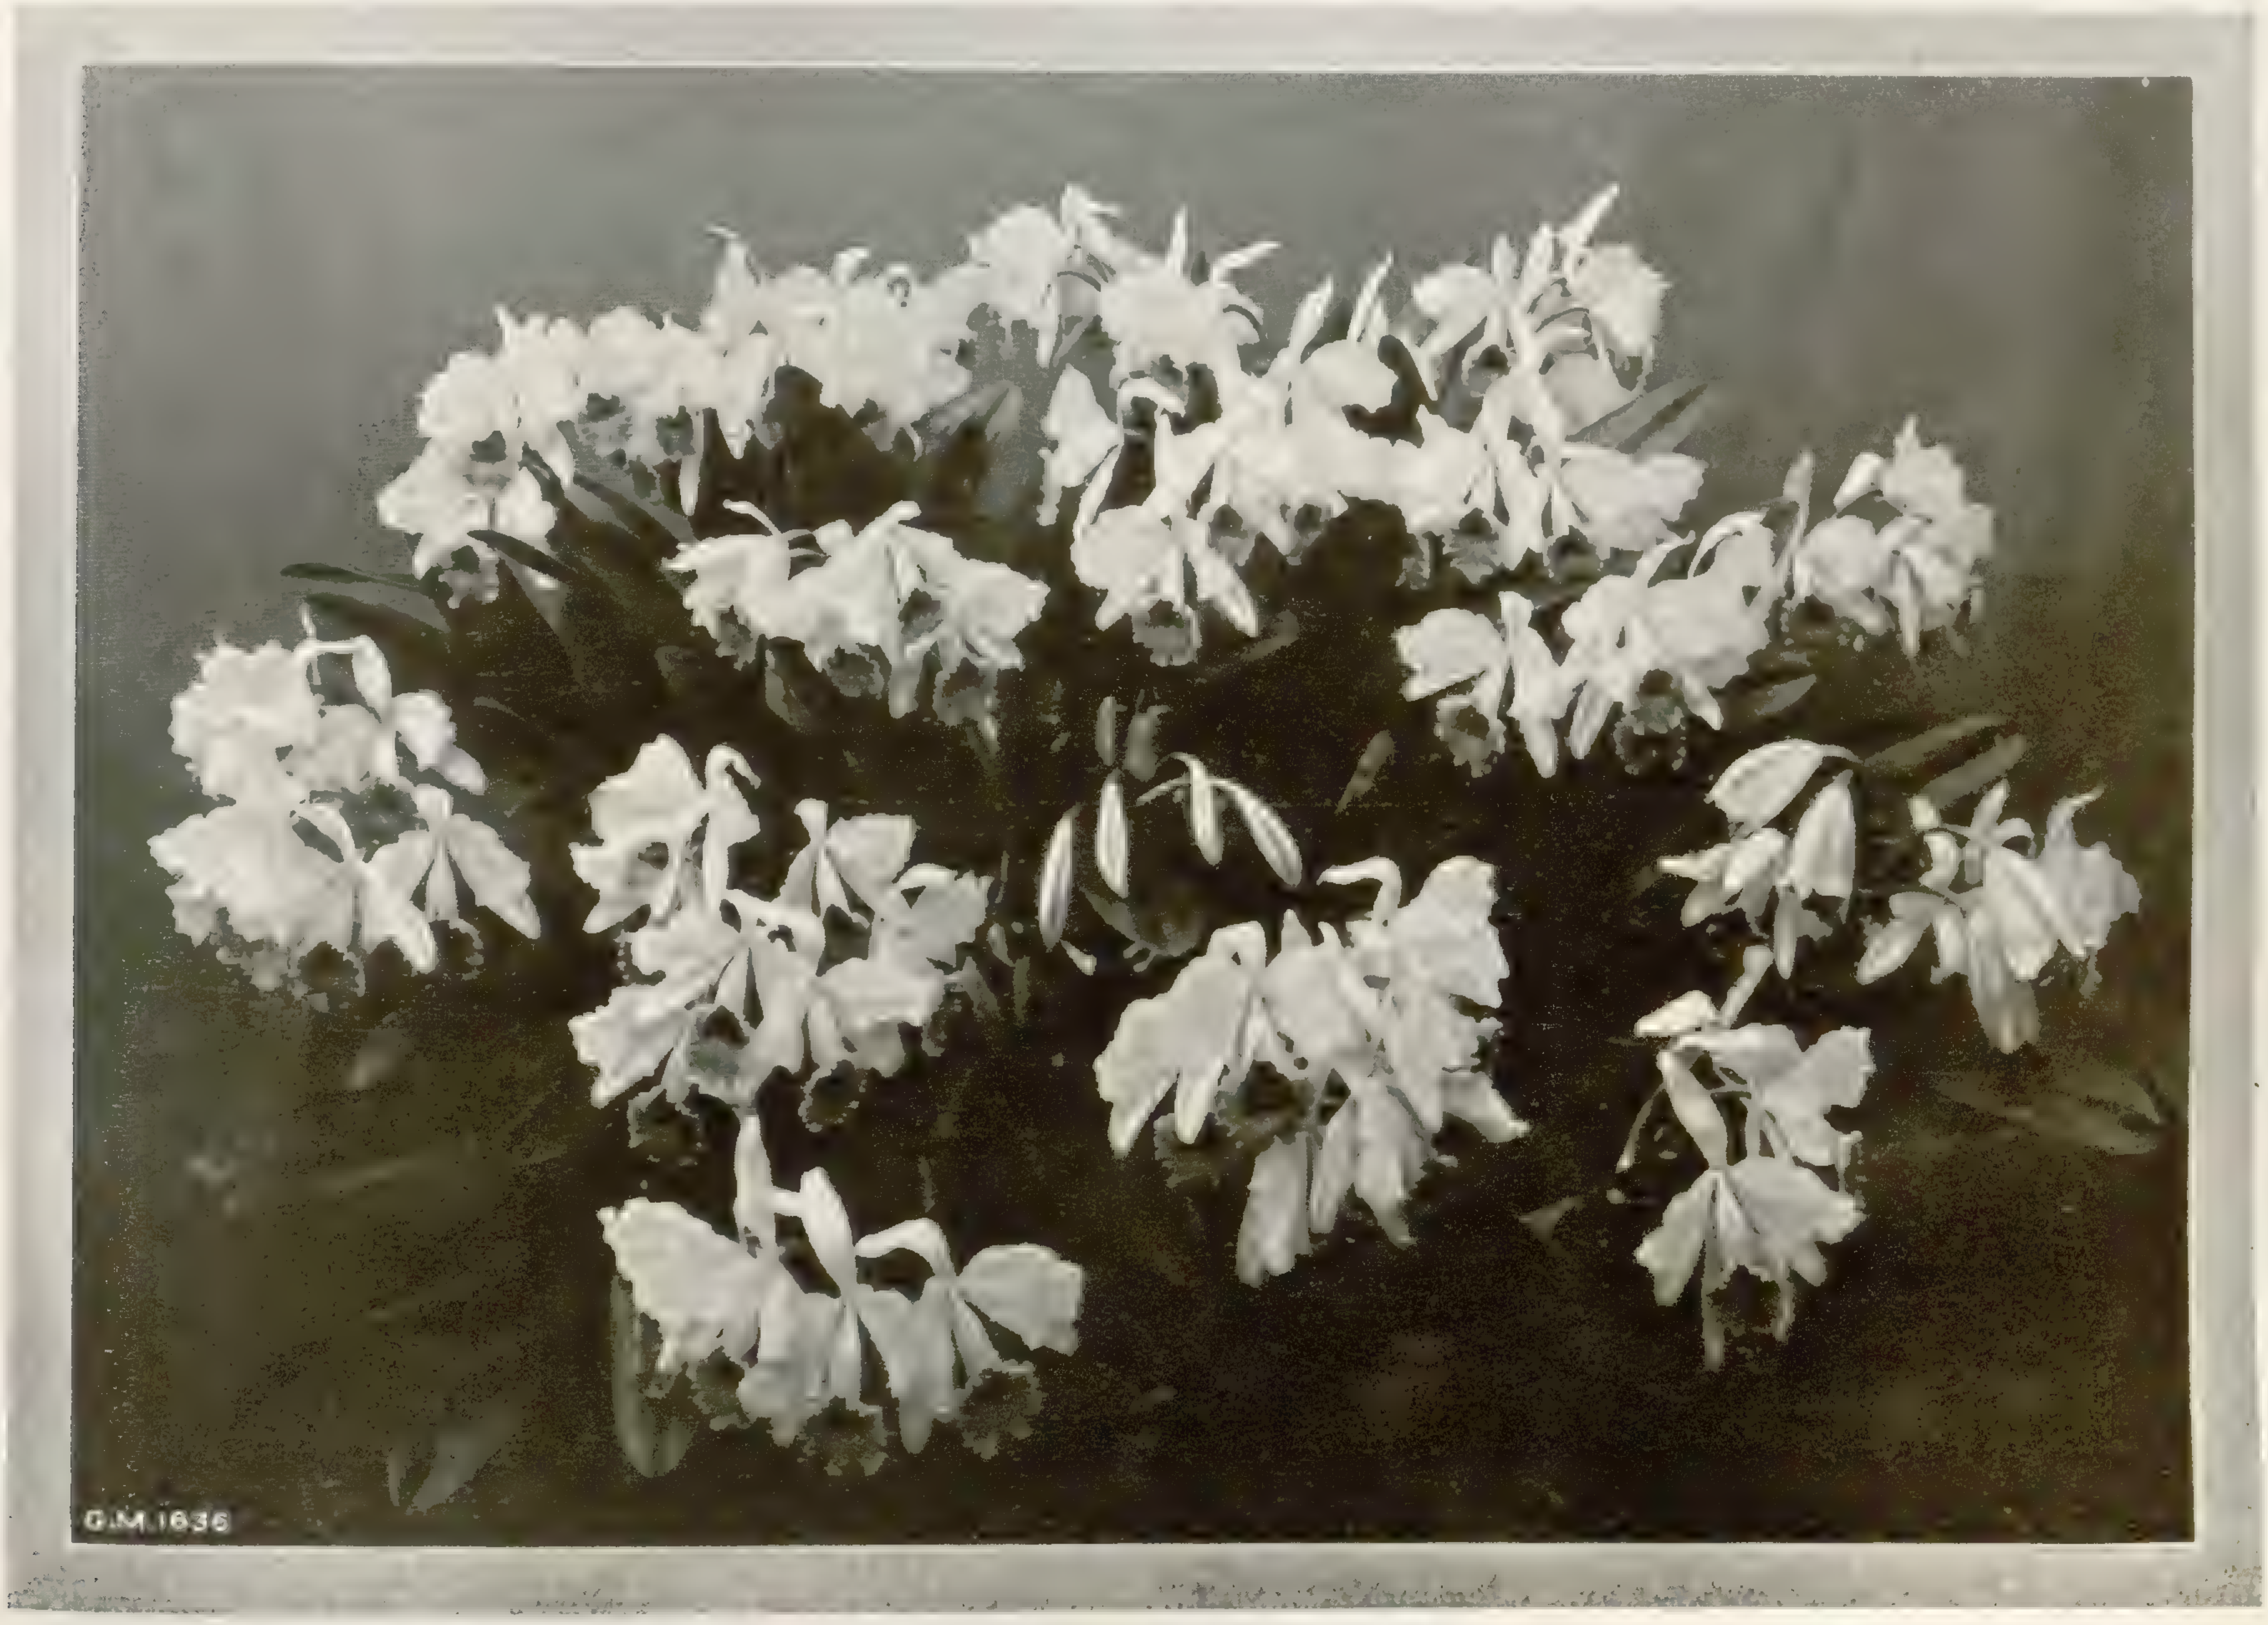
Hardy primulas will require a little more care than the plants already mentioned, as the seeds of many kinds will sometimes remain dormant in the seed pots for a year. When seeds can be saved from one's own plants it should be sown immediately it is ripe, for, as a rule, the newer the seed the quicker the germination. A cold frame in a shady corner is the most suitable place to raise the seedlings in, and the soil must not be allowed to dry. Such species as P. japonica, P. pulverulenta, P. Cockburniana, and P. rosea will reproduce themselves naturally from self-sown seeds, yet it is not wise to leave their perpetuation entirely to chance. Ramondia, androsace, soldanella, and the gentians are all readily grown from seeds, but a longer period of growth is necessary before flowering size is attained.

This work is extremely interesting, and also profitable, when one has a large rock garden to keep in order. A few hundreds of plants go a very little way when planting.

E. C. Pooley.

A FINE SPECIMEN CATTLEYA

It is a fortunate matter that in a few, though very few, collections of orchids, some attempt is made to show what wonderful specimens can be produced if skill and accommodation go hand in hand. Nearly everyone who grows orchids nowadays seems bent on cutting up their plants into the smallest examples, whereas years ago—when Mr. Wm. Marshall, V.M.H., was growing and showing orchids, for instance—the aim was to grow and exhibit specimen plants as large and as freely flowered as possible. There is no lack of cultural skill nowadays, but there does seem to be a lack of pluck on the part of owners and growers. However, for the few who can and do grow fine specimens there is the more praise and glory to-day Lieut.-Colonel Sir George Holford and his able grower, Mr. H. Alexander, have shown time and again that the Westonbirt collection is not only rich in species, varieties, and hybrids, but is rich in grandly grown specimen plants. One superb example is figured in the present issue, and the illustration represents Cattleya Trianæ Hydra, a charming variety with a very rich purple apex to the lip. In 1904 the plant had only three "leads" or growing points, but so skilfully was it managed that on February 14 last, when exhibited at the meeting of the Royal Horticultural Society, it carried no fewer than twenty-two spikes, and a total of ninety-six flowers. It need hardly be added that the Orchid Committee granted a Cultural Commendation as a testimony to Mr. Alexander's skill.



CATTLEYA TRIANÆ HYDRA.
A magnificent specimen orchid, with twenty-two spikes and ninety-six flowers; exhibited by Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury, Gloucester.

RAISING TOMATO PLANTS FOR OUTDOOR CULTURE.

It is generally held that plants which are eventually intended to be grown outside should not be raised in too much heat, and most of us have had experience of putting out plants in the open that have been brought on rapidly in a brisk temperature, of being disappointed by their subsequent lack of vigour. Though the tomato is of such a rampant habit that it will generally grow well eventually, no matter how much heat may have been used in the early stages of growth, such plants rarely set much fruit from the first couple of trusses of blossom, a loss for which no later fruitfulness can make up.

The tomato is a tropical plant, and in its earlier stages of growth has its constitution ruined for life by being subjected to a temperature as low as 34 or 35 degrees, though in the autumn it will often stand a degree or two of frost. Hence, unless one has some artificial heat for raising the seedlings there is great risk in a normal season of some one cold night reducing the temperature of the house or frame even below this point, to say nothing of that series of cold days and nights we often get as late as May. Failing a house where the temperature does not fall below 40 degrees, a hotbed is as good a place as can be wished for. Supposing this to be made up in the latter part of February, the seed should be sown in early March, in a pan, and a careful watch kept to avoid the risk of loss of seed or seedlings through overheating during the first two or three weeks. Set the seed pan upon an inverted pan or pot, and give air if there seems any danger. Afterwards, by covering up the frame at night, the temperature will rarely fall below 40 degrees in a normal season.

When the seedlings have their third leaf well developed they should be pricked out into thumb pots, inserting them more deeply than they were in the seed pan. If they show any sign of damping off before this stage they should be pricked out at once into light, sandy soil. When they have become moderately well rooted in these little pots, as they should be in ten days or a fortnight, they will be ready for shifting into 60-sized pots, the potting compost consisting of maiden loam to which has been added some bonemeal or basic slag. It is important that the soil in which the plants are grown, even at this early stage, should be rich in phosphates, as this promotes the development of a sturdy, short-jointed growth, which is favourable to fruitfulness rather than leaf and stem. Though we do not want to encourage unduly vigorous growth, we want to have well-rooted plants. If the plant before being turned out of the thumb pot is examined carefully, there will probably be noticed just below the seed leaves small white spots resembling minute pimples; these are the beginning, or growing points, of new roots, and when the plant is put into a larger pot it should be buried right up to the seed leaves, and then these embryo roots will push out into the surface soil like cucumber roots, and add strength to the plants. When the young tomatoes are shifted into 48 or 32-sized pots they should be potted firmly, using a rammer, firmness being scarcely second to an abundance of phosphates in conducing to fruitfulness. They should not be set so closely together in the frame, or house, that the lower leaves suffer from want of light and air, or even so that the plants are in the least degree drawn up.

Soon after being shifted into 32-sized pots the tomatoes will probably be too tall for the frame, and it is not easy to sink the pots to any extent in a hotbed, even if it were advisable. They must then be put in a cold frame, where the pots can be sunk in the ashes, or in a house to harden off, choosing genial weather for the change if possible, and this is rather an important point. When they have to be taken out of this frame they should have three or four days' shelter from both sun and wind, in order to harden their tissues, placing them under cover on a cold night. At this stage the plants should be stout in stem, with dark foliage, the roots showing both at the top and the bottom of the pot, and after they are planted out even a degree of frost will not seriously harm them.

Alger Petts.

ROMNEYA TRICHOCALYX.
Flowers pure white, with a cluster of rich yellow stamens in the centre.

ROMNEYA TRICHOCALYX.

A native of California, this species delights in all the sun it is possible to obtain in this country. It is a near ally of the well-known Californian Tree Poppy (Romneya Coulteri), and on account of a general similarity to that plant has been confused with it. It differs, however, in a marked degree in the calyx, which is oval in shape and covered with a mass of hairs, while in R. Coulteri the calyx is glaucous, devoid of hairs, and each lobe is tipped with a short, spreading awl. The habit of R. trichocalyx is more slender, and the flowers are produced more freely. These latter are usually four to five inches in diameter, occasionally as much as six inches, and are pure white, with delicate crimped edges and with a large cluster of rich yellow stamens in the centre. The foliage is decidedly handsome, and is of a lovely silvery grey colour, in fact, it is well worth growing in any garden as a foliage plant. Whilst in many gardens there is room for both species, if space is limited the new comer is to be preferred on account of its greater display of flowers. The romneyas are notoriously difficult plants to propagate from cuttings, but I have succeeded in doing so with pieces of the short jointed thin stems taken off in autumn and placed in sand under a bell-glass in mild heat. The usual method adopted for increasing them is by cutting up the thicker roots into pieces about three inches long and treating them exactly as cuttings. Adventitious buds are soon formed and they quickly make serviceable plants. Seeds are occasionally produced, but the seedlings are slow of growth in the early stages, and require careful handling, as they damp off very quickly with the least excess of moisture.

Orders to the **NATIVE GUANO CO., LIMITED,** 29, New Bridge Street, London, E.C., where 35th year's testimonials, etc., may be obtained. Agents Wanted

PREPARING GROUND FOR LAWNS AND GREENS.

Although either autumn or early winter is the best time to prepare ground for lawns and greens, yet, owing to building operations and other circumstances, this work has sometimes to stand over until spring. At this time of the year the same fine division of soil cannot be expected as would have been the case where the staple had been exposed for a considerable period to sharp frost. Still, there is no reason why excellent results should not be obtained, even at this late date.

Much as autumn operations may contribute to the success of making lawns and greens, this, in itself, is not sufficient to be taken as a guarantee that they will be satisfactory, as soils vary in their physical and chemical fitness, and lawns and greens may have level or sloping surfaces. In all cases they should be well drained in order that superfluous water may be able to escape and the air between the particles of soil become changed in the process, so that a sweet and lasting medium for the roots of grasses is secured. Sandy soils, of course, are apt to suffer from a lack of moisture in dry weather, and instead of providing artificial channels for the water to get away it will be decidedly advantageous to increase the cohesion of the particles by adding soil of a more tenacious nature.

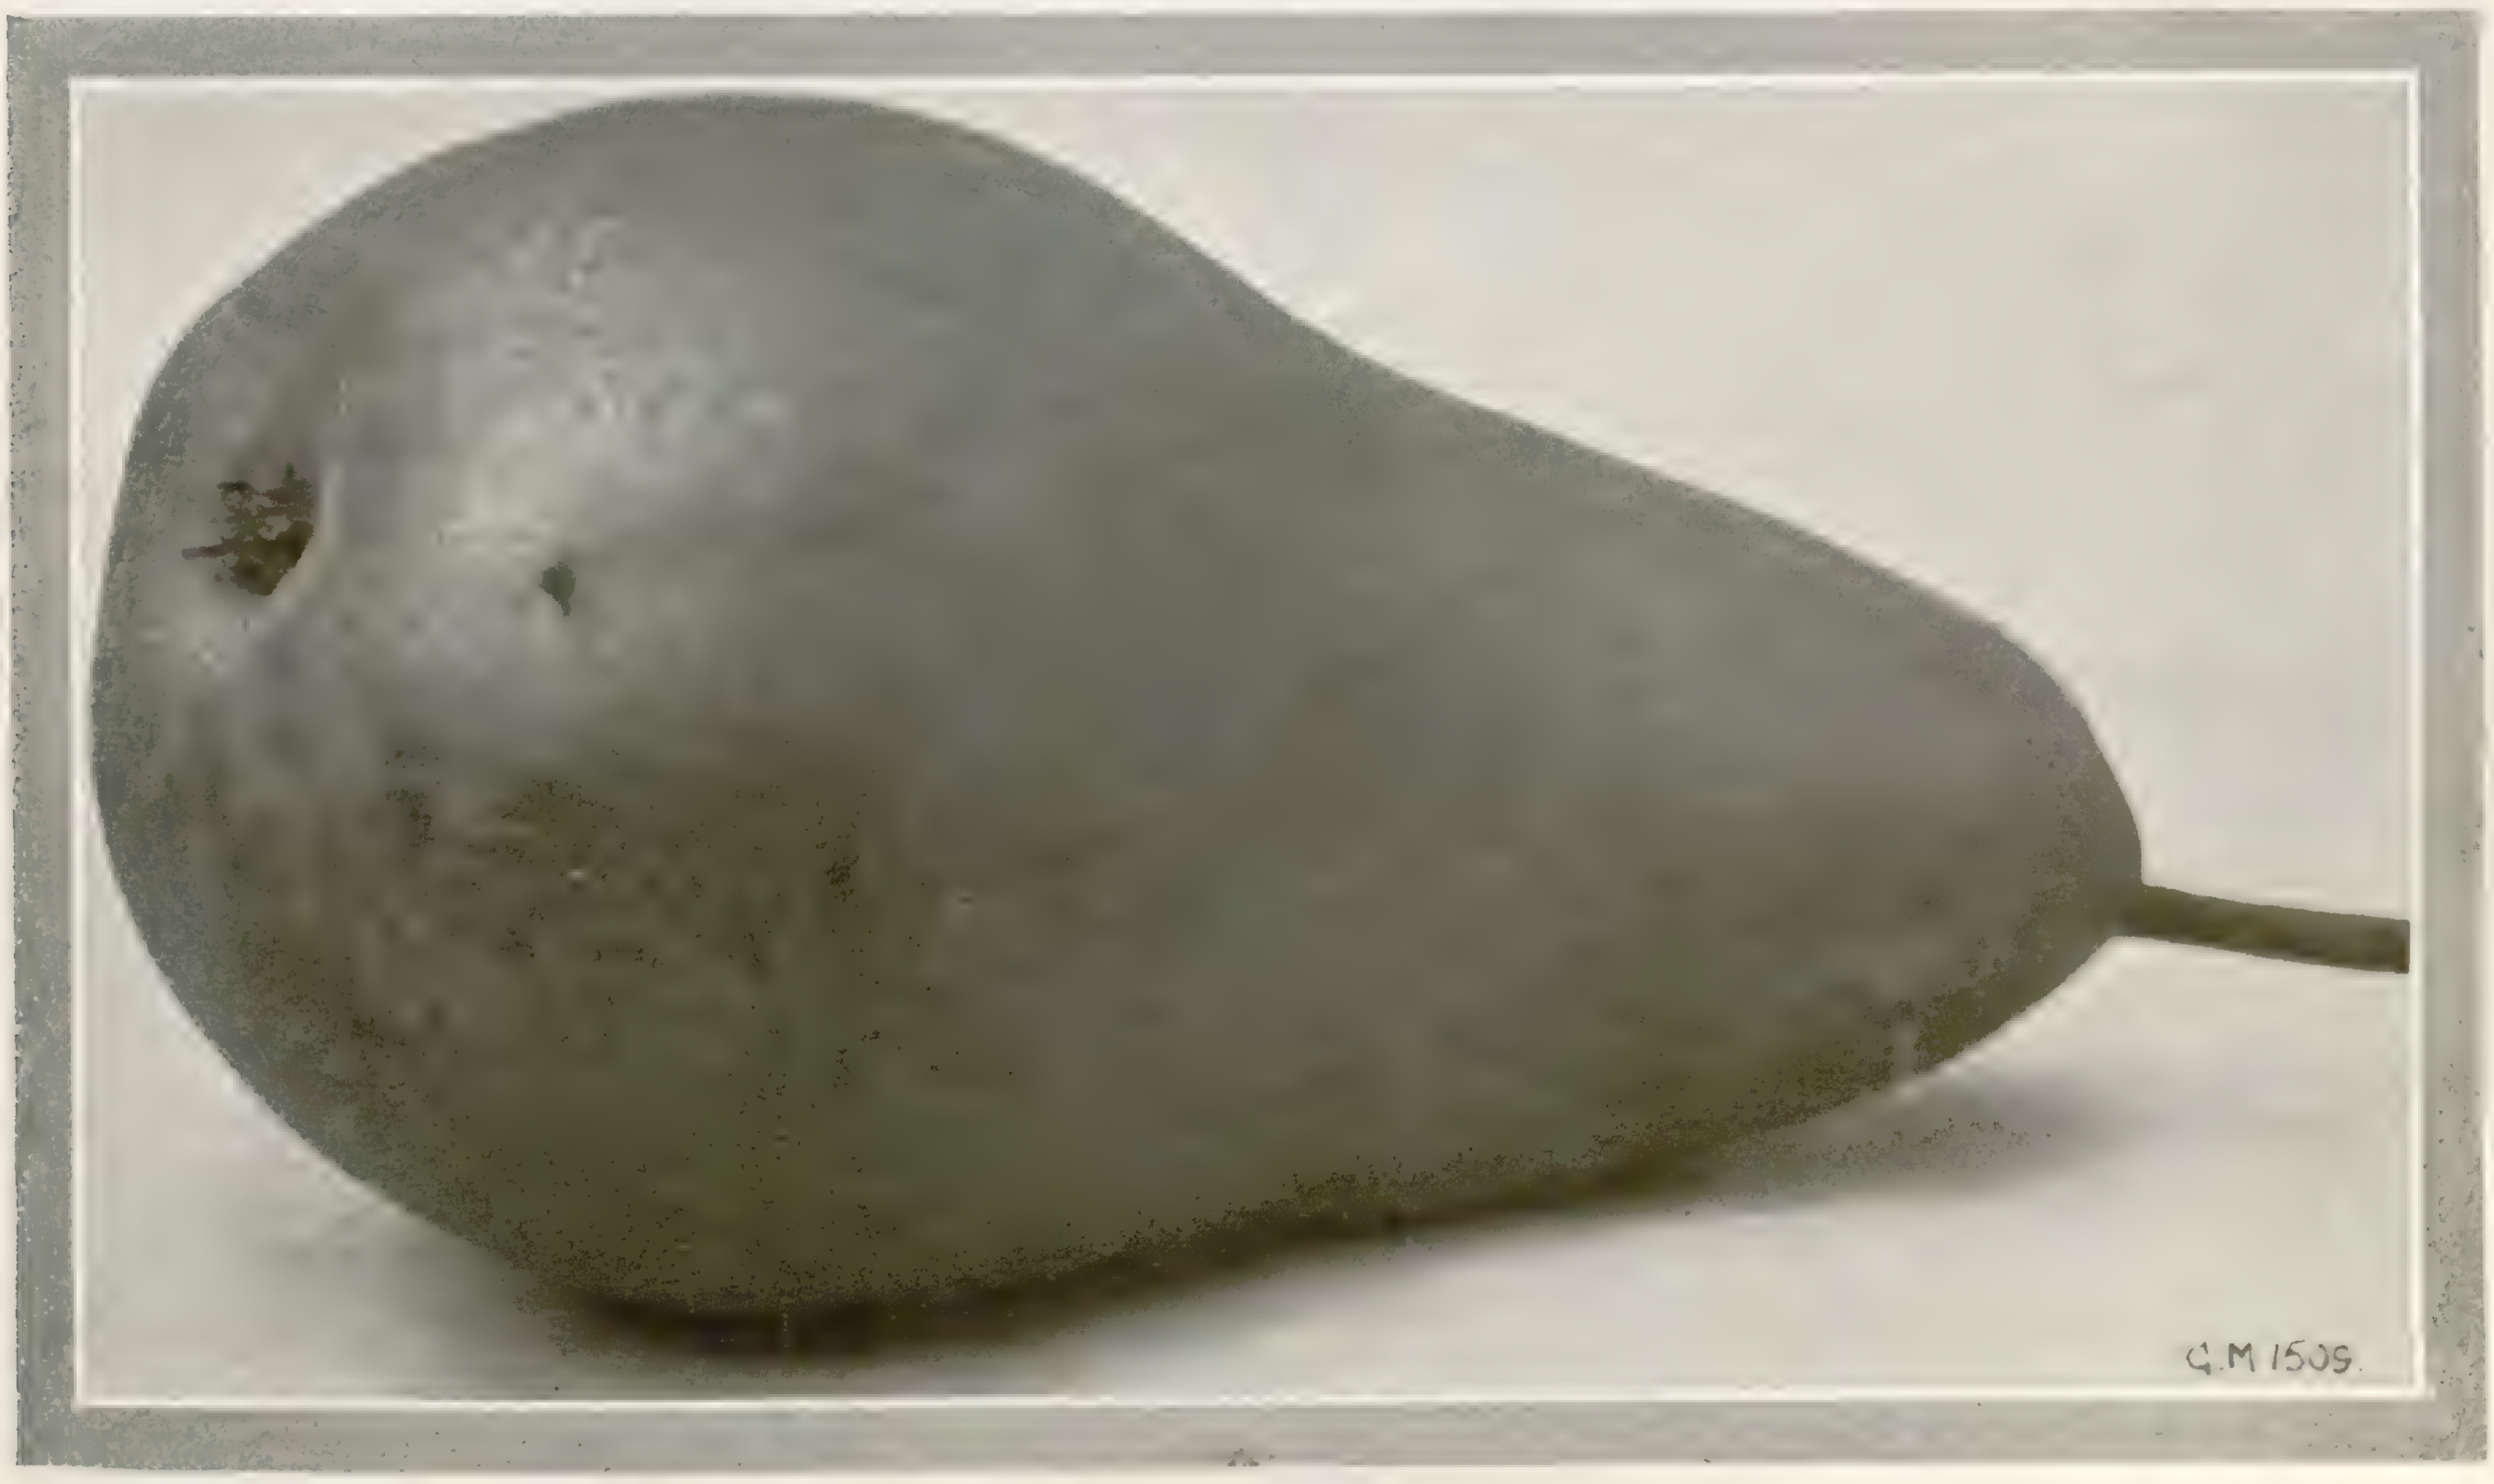
Loams and clays are so retentive of moisture that, with the exception of those resting on a gravel subsoil, within eighteen inches or two feet of the surface, a thorough system of drainage is indispensable to success. The kind of soil, and its situation, should determine the number of drains, but for ordinary purposes I have found ten feet apart a desirable distance to place them. Under normal conditions 2½inch field drain pipes, with a three-inch main, are quite equal to the work. The arterial drains should be from eighteen inches to two feet below the surface, and have about eight inches of cinders, clinkers, stones, or any other porous durable material on the top of them. In dealing with sloping ground the herring-bone system of drainage should be carried out, with the arterial pipes joining the mains at an angle of about 45 degrees. This is the system, too, to employ on bowling greens with a "crown." On level lawns, when there is only the surface water to be provided for, straight drains about fifteen feet apart, and joining a main at a right angle, will be ample for the purpose.

After the drainage operations are completed the next important step to take is to level the ground in accordance with the object aimed at. There are various ways of doing this, all of which have their advantages and disadvantages, but I have always found the most economical has been to take out an opening eight feet wide in the surface soil along two sides, level the subsoil to about the depth of the surface soil, and then finish with the surface soil of the adjoining eight feet. When the ground slopes the openings should be along the highest side, and the work proceed from this to the lowest side. Material from the substratum can then be found along the higher level to make good the lower side, and enable the work to be finished straight away.

Where there is much filling up to be done the soil should be solidified by treading every layer of about six inches in depth till the surface level is reached. This will prevent all shrinkage afterwards, and relieve those responsible for the maintenance of the lawn in good playing order from the trouble of making up deficiencies. Should the soil be deficient in plant food it is advisable to employ about one ton of well decomposed manure to every 100 square yards, and place this six inches below the surface. To distribute this evenly an opening should be taken out at one side, two feet wide and six inches deep, and the manure spread along the bottom. This done, the adjoining two feet by six inches should be placed on the top of the manure, then this trench treated similar to the first, and the whole ground dealt with in this way, and afterwards made solid.

If the ground is intended for seeds, and a grass turf free from weeds is desired, it is often advisable to fallow it all the summer, and sow down in the end of August or beginning of September. During the summer months the surface of the ground should be stirred only about half an inch deep fortnightly, to kill all the weeds which make their appearance, and to get all the seeds in that thin layer to germinate before seed sowing time arrives. In employing this method of lawn and green making it cannot be too strongly emphasised that the most important factor in securing a really good lasting turf lies in keeping the present surface soil on the top. This has taken centuries to attain its fertility, and before the subsoil could be brought up to such a fine state of division and stored with such a quantity of plant food years must elapse.

Hibernia.



PEAR TRIOMPHE DE VIENNE.

PEAR TRIOMPHE DE VIENNE

Triomphe de Vienne is a large and very handsome pear, and one that is good alike for exhibition and dessert. It is of elongated and shapely form, and a tree carrying a good crop, whether in the open or against a wall, is a fine sight. The variety crops freely, and its russety skinned fruits are of excellent flavour. An early pear, coming into use in September and October, it must not be allowed to hang too long or some of the fruits will rot at the core. Owing to its regular and free-cropping habit Triomphe de Vienne is a good pear for a small garden, but as the fruits do not keep well for any great length of time, as a rule, not many trees are needed in a private garden.

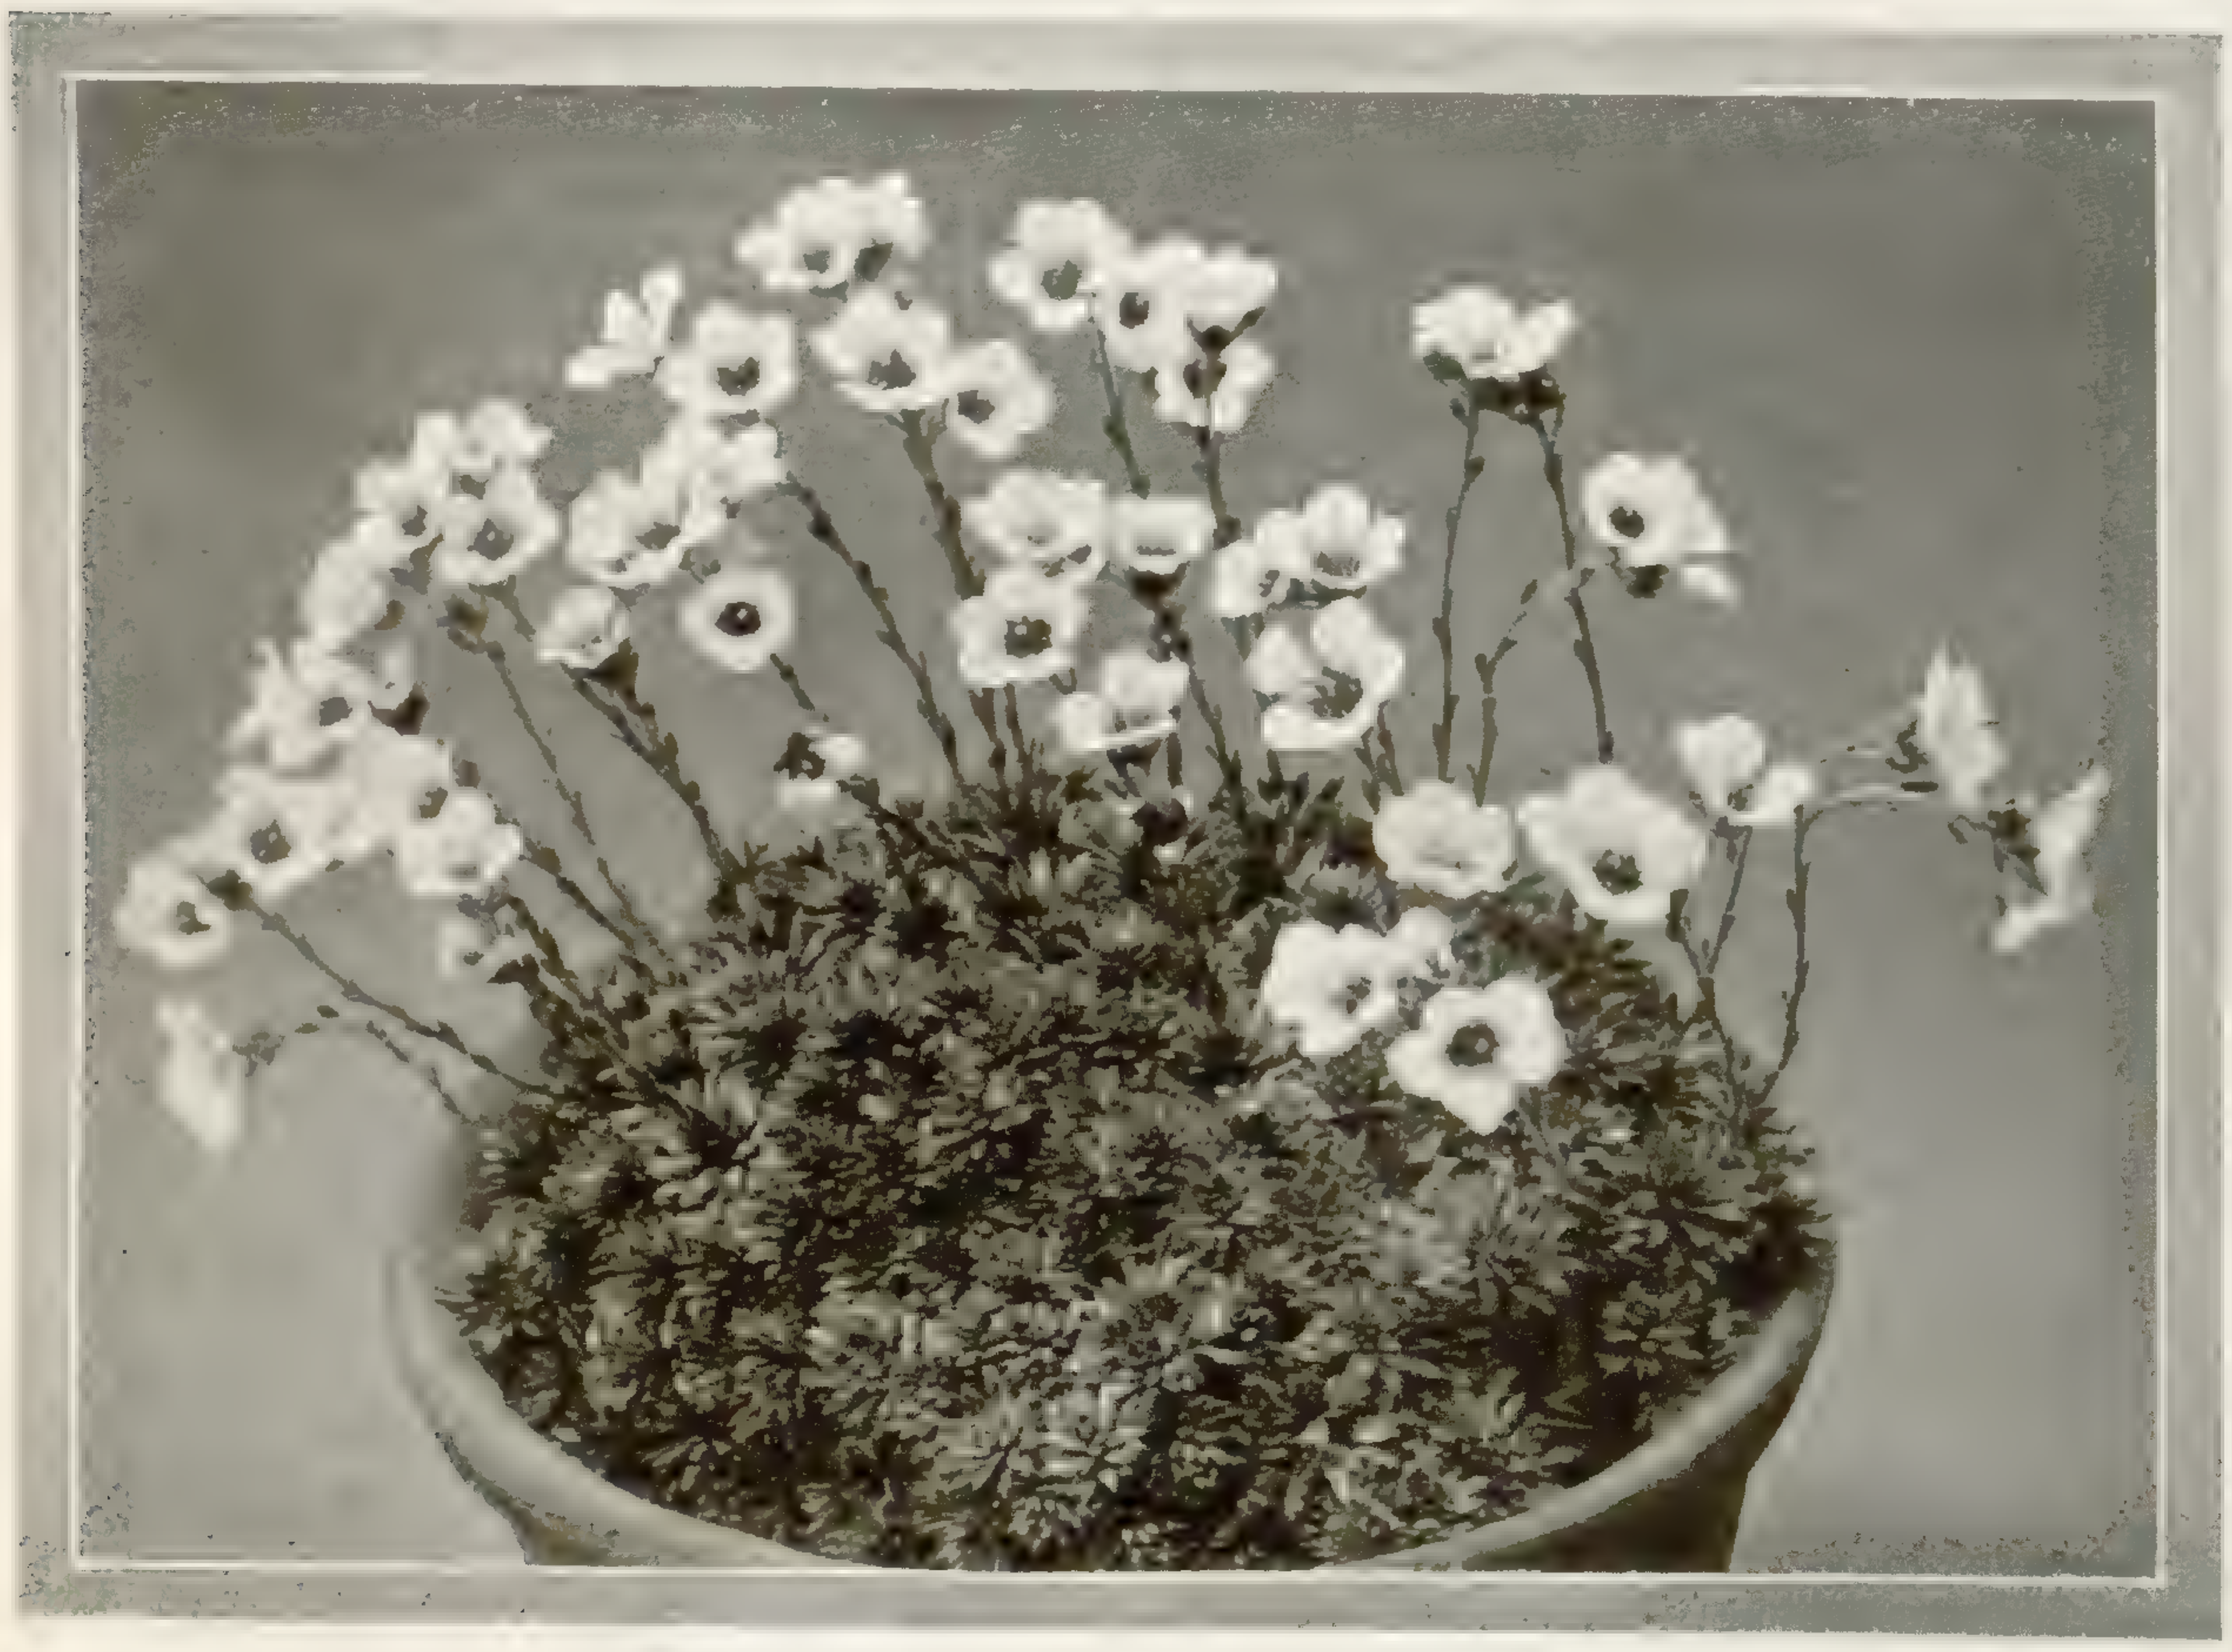
NEW PLANTS, ETC.

CYMBIDIUM VEITCHI.

This striking and interesting orchid is a hybrid obtained by crossing Cymbidium Lowianum with the distinct C. Devonianum. The flowers are of medium size, and shaped very like those of C. Lowianum, but the spike is more lax and pendulous than in the latter species. Sepals and petals are alike pale green, with brownish shading, while the lip has its apical portion coloured very deep and dark brownish-crimson. A.M., R.H.S., February 28. Messrs. James Veitch and Sons, Lim., Chelsea.

PRIMULA WINTERI.

In this new primrose we have another fine addition to a very useful and extensive family. The newcomer is hardy, having been found at an elevation of 12,000 feet on the Himalayas. It is a lowly-growing species, and one that will appeal to lovers of alpines. The growth is somewhat like that of our common primrose, except that the deep green leaves are freely dusted with a white mealy powder. The flowers are on long pedicels, and borne in clusters at the end of a very short spike, so that the blooms do not extend much beyond the leaves. Individually the blooms are like those of an alpine auricula, pale lilac or rose-pink in colour, with a white area round the greenish eye. The species promises to show some amount of variation in colour, and in the size of the flowers, but in any case it will surely become popular if it takes kindly to the conditions in this country. F.C.C., R.H.S., February 28. Messrs. R. Gill and Sons, Penryn, Cornwall.



SAXIFRAGA BURSICULATA.

A pretty, low-growing, dense plant; a hybrid between two popular species. Flowers white. A.M., R.H.S., February 28. Mr. E. H. Jenkins, Hampton Hill.

SAXIFRAGA BURSICULATA.

A dense low-growing hybrid between S. Burseriana and S. apiculata; it is very free-flowering, and the effective blooms are pure white. A.M., R.H.S., February 28. Mr. E. H. Jenkins, Hampton Hill.

BETULA MAXIMOWICZI.

A beautiful birch from Japan and Manchuria, with broad, light green leaves, that have a distinctly serrated margin. The tree is said to attain a height of 100ft. The species was first found by Maximowicz, but seeds were first sent to this country by the late Mr. James H. Veitch. Later, seeds reached Kew from the Arnold Arboretum, in 1893, and young plants raised therefrom. "Bot. Mag.," t. 8,337.

ROSA MOYESI.

This interesting and beautiful rose was figured in our issue of June 20, 1908, p. 478. It was sent home by Mr. E. H. Wilson, and has been found to grow in a position where the majority of garden roses succeed. It can be raised from seeds or increased by cuttings inserted in heat in August. Rosa Moyesi is from Western China, and we owe its introduction chiefly to the efforts of Mr. E. H. Wilson when collecting for the Messrs. J. Veitch and Sons. It makes a shrub about 6ft. or 10ft. high, and not very prickly. The blood-red flowers are two to two and a-half inches broad, the calyx and the outer side of the petals being purplish. "Bot. Mag.," t. 8,338.

STYRAX HEMSLEYANUS.

This flowering shrub, or small tree, from Central China, promises to be quite hardy, and to provide a welcome addition to other good things sent home by Mr. Wilson. It was discovered, however, by Dr. Henry, in 1888. The light green leaves are broadly ovate, with serrate margins. The flowers are about an inch across, white, and borne in short racemes. "Bot. Mag.," t. 8,339.

IRIS WILSONI.

A beautiful iris that resembles I. siberica in habit, and, at Kew, has been found to succeed under conditions suitable to that species. Found in Western China, and also in Central China, by Mr. E. H. Wilson, I. Wilsoni has yellow flowers; the falls are marked with red-purple over the central portion, while the narrower "claw" is veined with purple along the edge. The inner segments are clear yellow. "Bot. Mag.," t. 8,340.

PRIMULA LITTONIANA.

This interesting and curious primula was found by Mr. Forrest in Western China when collecting for the Messrs. Bees. It has so far proved quite hardy. The style of the spike and the way the flowers open suggest a glorified and beautiful plantain. It grows from one to two feet high, and the radical leaves are about seven inches long, and hairy. The erect flower stem rises about eighteen inches high, carrying at its apex a dense spike of small blue flowers, these being set closely together for a distance of from three to five inches; the calyx is pink, and the unopened flower buds show a deeper blue colour than the expanded flowers. The species was figured in the Gardeners' Magazine of July 10, 1909, p. 528. "Bot. Mag.," t. 8,341.

CARROTS ALL THE YEAR ROUND.

(Concluded from page 152.)

The autumn and winter supply is as important as the earlier crops, and provided there is a suitable soil, anyone may have young carrots all through autumn and winter. But there must be genial soil to sow in, for a winter crop in a cold, badly drained soil would be certain to fail. The soil must have been well worked and free from pests of all kinds. It is often thought that carrots are not hardy, but such is not the case. For many years I have allowed the roots to winter in the ground, and though severe weather will often spoil full-grown roots, making them split, the smaller roots, especially in a sandy or light soil, will keep well, if not sown too early. On the other hand, in badly-drained soil it might be well to lift and store the largest-sized roots and leave the smaller ones. Sowings should be made in July; in the south I always sowed early in August, and used such varieties as Sutton's Early Gem, Scarlet Model, Early Nantes, or any of the Short Horn type, and selected an open quarter, and allowed ample room between the rows, so that in severe weather it was an easy matter to draw earth up to the roots. Should protracted frost follow, it is an easy matter to cover a portion of the quarter with litter to allow the roots to be lifted for use. Grown thus there is a supply from the late autumn until the first sowings are ready.

It will thus be seen that a full year's supply may be secured, but those who do not wish to go to this trouble may with advantage sow early as advised. Sow again in March (these are small sowings), and make a larger sowing early in May. This will give roots plenty large enough to store in November, but cool storage is essential, just free from frost, with plenty of soil or sand between the roots to keep them from shrivelling.

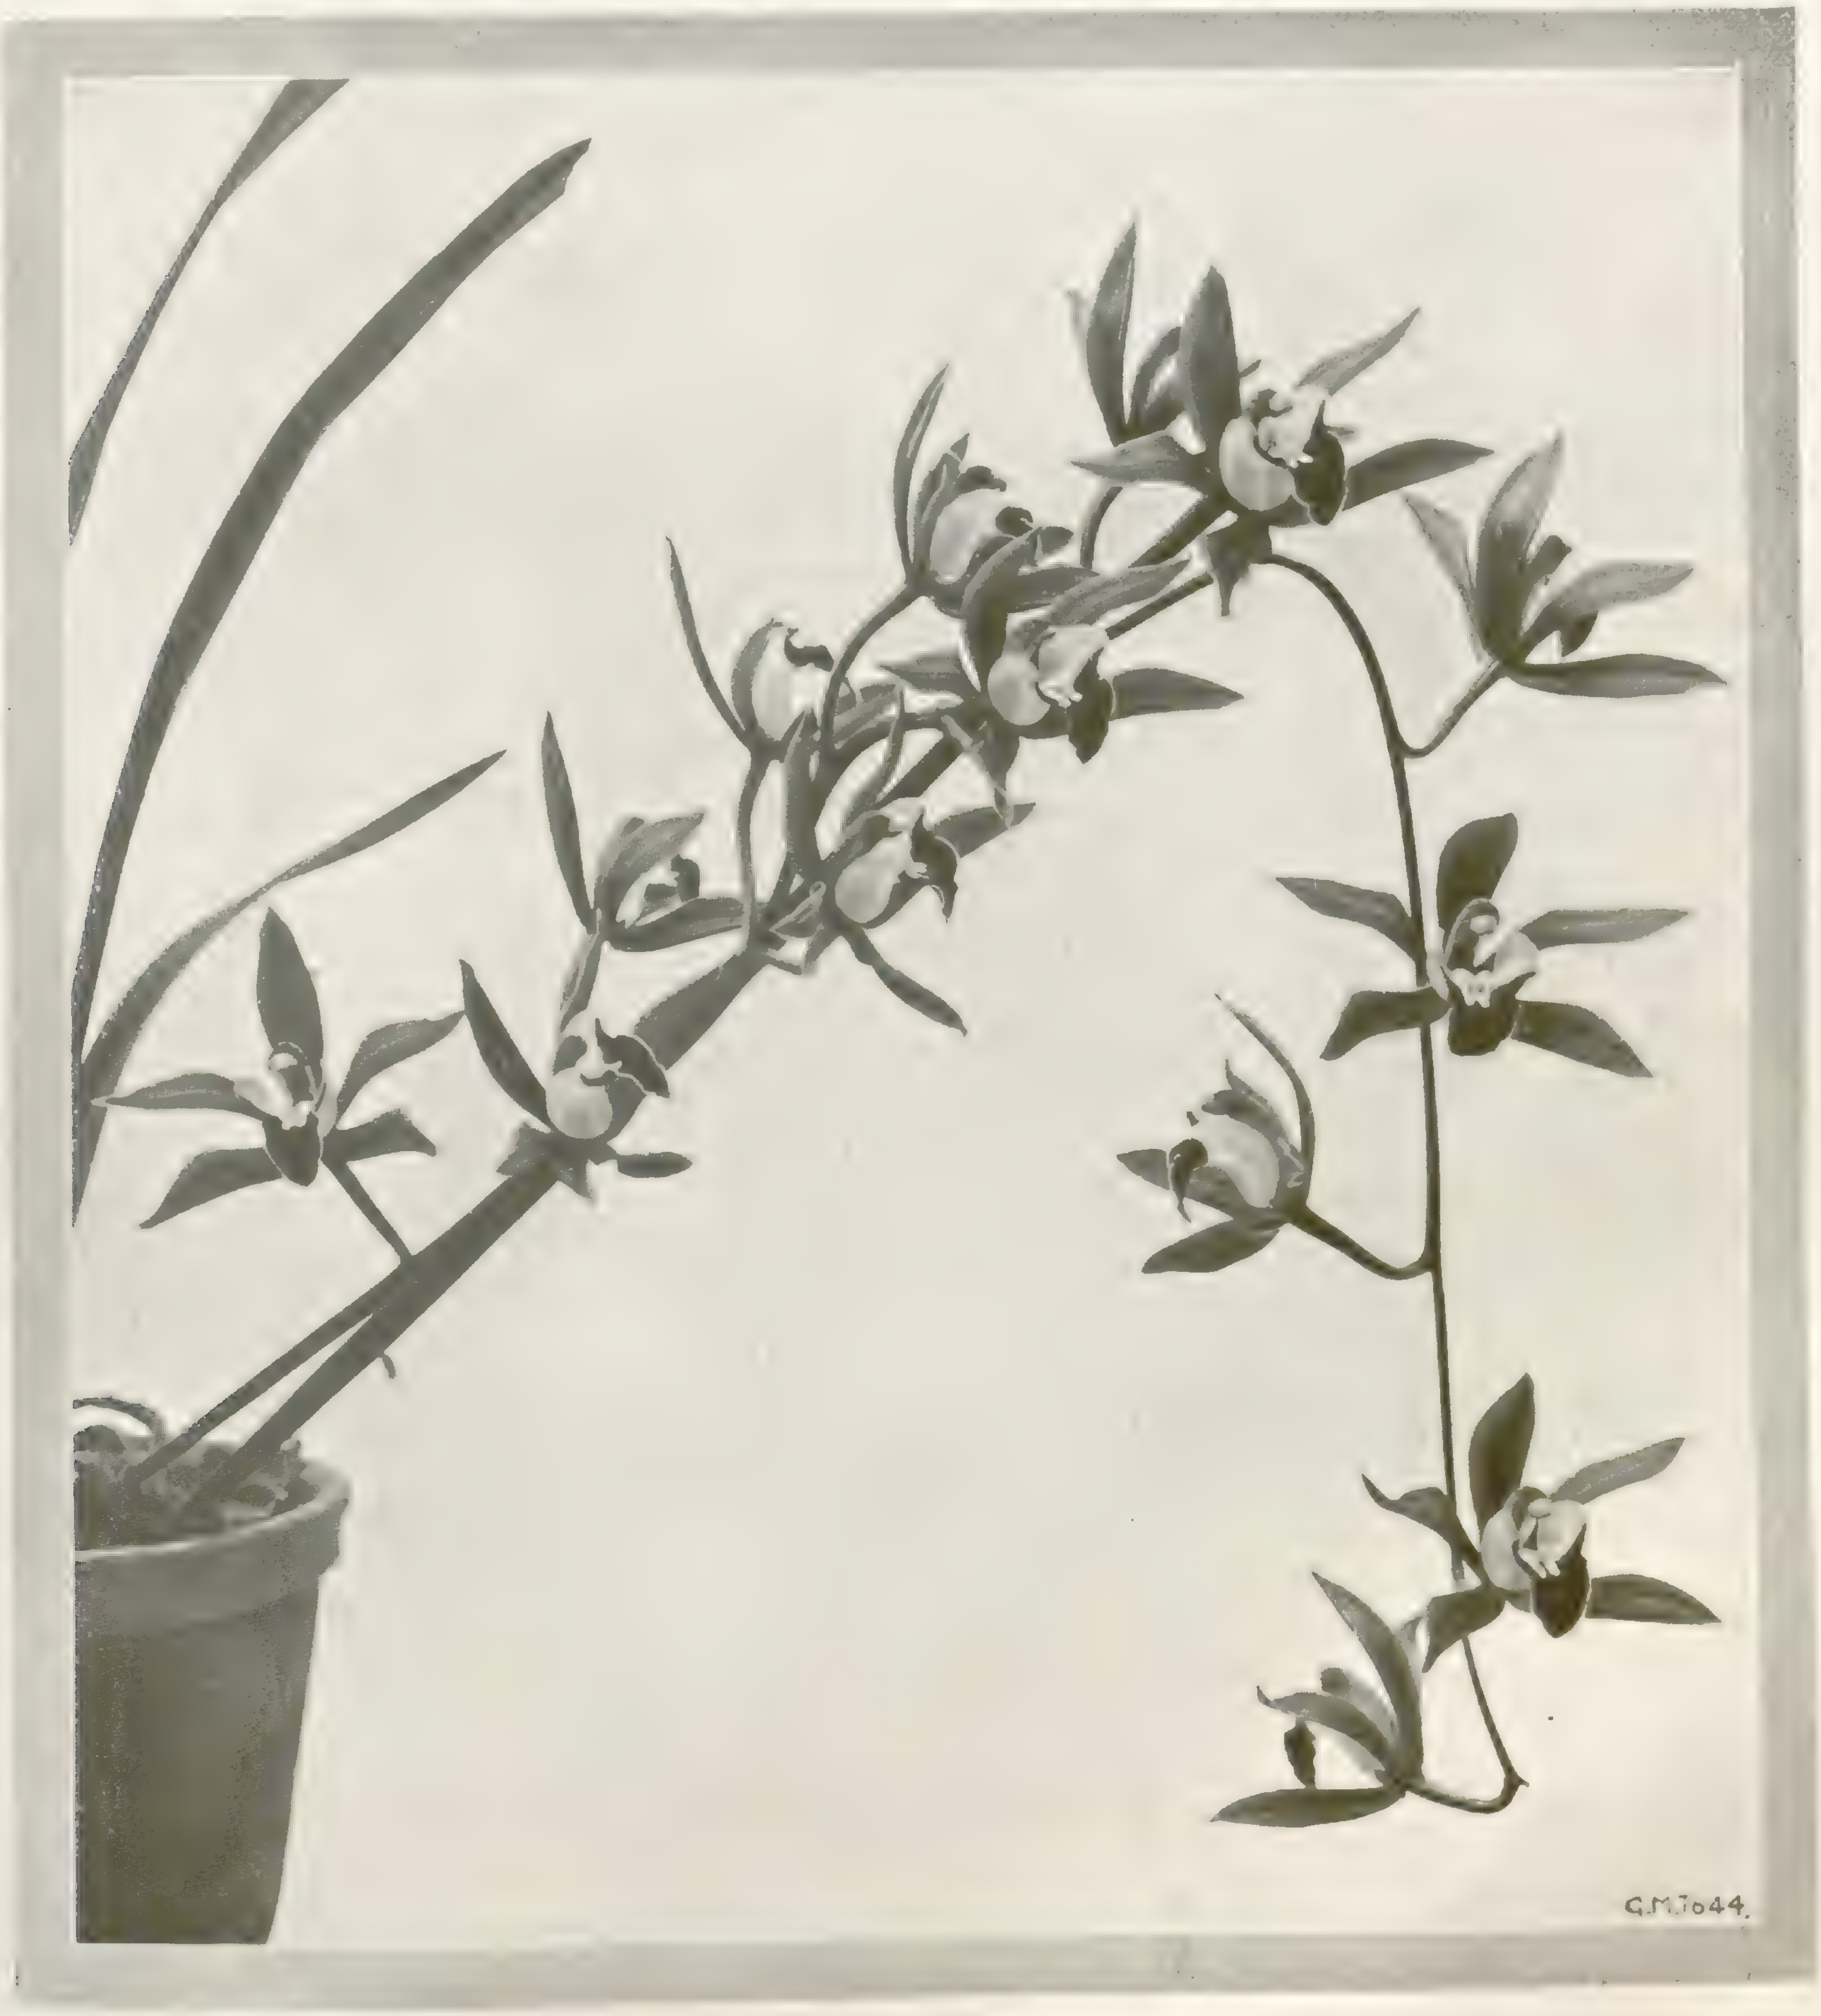
Carrots are frequently attacked by wireworm and carrot maggot, and often the early crop that forms large roots suffers most. Crops sown as advised often escape. In land badly infested with these pests I have found gas lime a splendid help, but the lime should lay on the land early in the autumn for a few weeks, be broken up very finely, then double dug in, and the surface left as roughly as possible until sowing time. Fresh lime and soot used freely are also splendid aids, and can be used almost at any time, and in old garden soils I have often found it advantageous to omit animal manures and give artificials. Fresh animal manure should not be used for carrot crops.

G. Wythes.

Cauliflowers.—Gradually harden off the plants that were pricked out in boxes and frames from the January-sown seeds, for planting out later. Another sowing will be required either in boxes or in a sheltered warm position outside to give a succession to the earlier plants. For this sowing I like Early London, as it has not the same tendency so many varieties have to turn in all together, and often gives a yield over a long time if a cool open position is given the plants.—C. Flack.

REPOTTING HIPPEASTRUMS.

Very diverse opinions are held as to the most suitable season for repotting hippeastrums, and, having tried various experiments in that way, I was pleased to see that the opinion of your correspondent, Mr. W. J. Jennings (page 86) entirely coincided with my own. The generally accepted idea is to shake out and repot early in the year, but I feel confident that the blossoms do not develop so well, nor retain their freshness so long, as in the case of thoroughly established plants. If repotting, when necessary, is carried out directly the flowers have lost their beauty the roots start away freely into the new compost, which serves to build up the bulb for another flowering season. With the assertion made by your correspondent that hippeastrums are often given too much heat I entirely agree, and look upon a cold frame facing due south as a good place for them during the latter part of the summer, until the nights grow cold and damp in autumn.



CYMBIDIUM VEITCHI.

A distinct hybrid, with green, brown-shaded flowers, and a crimson apex to the lip. A.M., R.H.S., February 28.
Messrs. James Veitch and Sons, Chelsea.

One great advantage in dispensing with fire heat during the summer months is that the plants keep much more free from insect pests, as thrips and mealy bug increase rapidly under warmer conditions. What is more, the leaves are of a far sturdier nature, and the bulbs much firmer. When developed under these conditions the hippeastrums may be kept safe and sound during the winter in a minimum night temperature of 45 degrees, rising somewhat during the daytime, that is to say, just such a temperature as is maintained in an ordinary greenhouse. Even where no warmer structure than this is available hippeastrums may be well flowered, though, of course, the blossoms will be a good deal later than if they are brought on in greater heat. In a cool house such as referred to the soil should be kept pretty dry till the end of February, or thereabouts, for if the plants are induced to start earlier a spell of exceptionally cold weather may give a decided check.

This brings one to the question whether the annual repotting of hippeastrums so generally followed is really necessary, my opinion being that it is not so, providing, of course, that the roots are in a good condition. Instead of fresh soil they may be assisted with liquid manure, or some other stimulant, during the growing season. On this point my preference for hippeastrums, and, indeed, for all fleshy rooted plants, is, when a stimulant is necessary, to use a mixture of liquid manure made from sheep or cow droppings and soot water, in preference to any of the chemical manures now so popular. With regard to annual repotting, I know of one successful cultivator who repots half his stock each year, and another who divides his stock into three portions, so that each plant is repotted every third year. Of course, a compost of a lasting nature is very necessary.

W. T.

PROTECTION OF WALL FRUIT TREES.

In most gardens various schemes are devised for the protection from frost of fruit trees growing against walls by the use of nets, tiffany, light canvas, hessian, etc.

Usually the south walls not monopolised by ranges of lean-to glasshouses are used for supporting trees of some of the choicest hardy fruits, and, in many instances, ample arrangements are made to safeguard them during March, April, and May.

The method adopted here in Sussex for protecting peaches, apricots, and pears against south walls is by no means an uncommon one. It consists of a coping made of weather boards, in sections sixteen feet in length; these are temporarily fixed to iron brackets by thumb screws and nuts in a sloping position, and they project out from the top of the wall eighteen inches. The blinds correspond in length to the sections of the coping, and are deep enough to reach within one foot of the ground; the upper edge is tacked to a lath attached beneath the front edge of the coping by screws. The blinds, which are made of thick tiffany, are drawn up and let down by means of pulleys and cords; five pulleys are alloted to each blind, and these are fixed to the underside of the coping. Light poles are placed eight feet apart, with their bases let into the border a few inches, and four feet away from the foot of the wall. These are long enough to reach the coping, and are fixed to the brackets supporting it, so helping to relieve some of the weight of the blinds. The blinds, when let down, are kept taut by tying them to the foot of the supporting poles.

The trees against the walls are planted sixteen feet apart; between them are constructed temporary shallow frames ten feet long, two feet wide, and six inches deep, made with rough boards, which are kept in position by being nailed to short piles driven into the border a few inches. These frames are filled with light soil, usually old potting soil, and when it becomes necessary to protect the expanding flowers on the fruit trees, which, with us, is generally about the second week in March, we commence planting out calceolarias, early-flowering chrysanthemums, etc., in the shallow frames; in others, about the first week in April, such things as dianthus, asters, stocks, Phlox Drummondi, and ageratum, etc., are pricked out thinly, and by the time their summer quarters become vacant in the flower beds and borders they make nice sturdy plants, and lift with good balls of soil attached to the roots.

Here, too, we have an admirable site for bringing on celery plants and early lettuces. If a batch of dwarf beans is raised, by sowing the seed thinly in four-inch pots during the second week in April, and given a gentle heat in which to germinate, they can be planted out early in May in the frames, which will by that time have become vacant, as the chrysanthemums will have been removed to their flowering quarters. These beans will come into bearing quite a fortnight earlier than the most forward sown in a sheltered border. We also find the frames a convenient place for hardening off many varieties of bedding plants grown in pots and boxes.

It will be seen from this that by utilising such a position for the various plants mentioned, much can be done to relieve the limited accommodation of pits and frames at a time when these are so much needed. When the frames become vacant the boards are removed and stored away until required another season. The coping and blinds are taken down when all danger from frost and cold wind is past, which with us is usually the last week in May.

T. B. Field.

THE SPRING PRUNING OF SHRUBS.

The question sometimes arises as to which shrubs ought to be pruned in spring and which not, for it sometimes happens that people with little knowledge of shrubs have pruned away wood in spring which, a month or two later, would have borne flowers had it been left untouched; on the other hand, shrubs may have been left unpruned, which, had the pruning knife been used, would have given a great deal better results. Therefore, in the succeeding notes attention is directed to certain shrubs which may be benefited by pruning during February or March

As a rule, those plants which bloom after the end of June produce their flowers from young wood, consequently any which require pruning may be pruned during early spring, in order that advantage may be taken of a long growing season. Then, with shrubs which blossom early, all necessary pruning must be done as soon as the flowers fade. No better time can be found for evergreen pruning than spring, April being a good month, as new growth commences almost at once and soon obscures unsightly branches.

Taking late-flowering shrubs, we find that the autumn and late summer-flowering spiræas require attention. These must have their branches well thinned out, and those which are left cut back at least half-way. During the thinning care must be taken to remove the older branches, for from these the inflorescences are never so fine as from younger wood. Such kinds as japonica and varieties, salicifolia, Douglasi, Menziesi, Aitchisoni, and Lindleyana may all be pruned. Most species of cytisus and genista do not require pruning until after the flowers have fallen, but there are a couple of kinds, one Cytisus nigricans, and the other Genista elatior, which may be pruned in spring. They may be cut back to within a few buds of the base of the last year's wood, but not into two-year-old wood.

Hypericums require cutting back and thinning out as recommended for the spiræas, while the autumn-flowering ceanothuses must be pruned at this time. Last year's shoots may be cut well back, the weaker ones to within two or three buds of the base, and the stronger ones to within six or nine inches of the bottom. Care must be taken to leave well placed young wood to take the place of older branches which are becoming weak. Buddleia variabilis and its several varieties are all improved by severe pruning, the finest inflorescences usually being obtained from plants which have been cut down to within a few inches of the ground. Vines should be pruned over if they have not been already done, that is the various ornamental kinds of vitis.

Autumn-flowering heaths should have their old flower heads removed, and the same thing may be done with the various forms of Calluna vulgaris. Clematis will probably have been pruned ere this; if not, the various Jackmanni forms may be cut back to within a few eyes of the base of last year's wood. The same may be said of the viticella forms, whilst the varieties of C. lanuginosa need not be cut quite so hard. C. florida and patens must not be pruned at this time. C. heracleæfolia and its many varieties may all be pruned to within a few buds of the base of last year's wood. Where such plants as Paulownia imperialis, Ailanthus glandulosa, and Rhus typhina are grown for the sake of the ornamental effect of their large foliage, the stems should be cut down to within a few inches of the ground without delay. In all cases where severe pruning is practised, it must be remembered that it is an exhaustive method of culture for the plant, hence the necessity of giving a good top dressing of manure occasionally. Coloured stemmed shrubs, such as willows and cornus, may have their branches cut back about the middle of March, whilst coloured foliaged elders are more effective if cut down well in spring.

Turning to subjects which require pruning as soon as the flowers fade, one which requires early attention is Jasminum nudiflorum. By cutting this in well each spring better results are obtained than when it is allowed to grow on year after year unchecked. Forsythia suspensa, when grown as a bush in the open, may be pruned back well as soon as the flowers fade. When grown against a trellis, however, less pruning is desirable, for in such cases slender pendant shoots are more appropriate than the strong upright ones which are encouraged by much pruning. The various brooms may be cut back when the flowers fade, below the flower heads.

Spring-flowering spiræas require very little pruning unless they are outgrowing their positions, when they may be thinned out well, and reduced in size. Lilacs may have the weak wood and suckers cut away, whilst it is a good plan to remove the flower heads as soon as the flowers fade, in order that energy is not wasted on the production of seeds which are not required. Any shrubs which have out-grown their positions may be pruned as the flowers fade. It must, however, be borne in mind that they must be well thinned out as well as cut back.

Evergreens not grown for the sake of their flowers may be pruned in April, as already stated. At that period it is possible to prune severely, and have the shrubs presentable again at an early date, whereas if the pruning were done in autumn they would be unsightly for many months. When rhododendrons have to be cut back, which is not often necessary, the work may be done as soon as the flowers fade, but if severe pruning is necessary it sometimes pays to sacrifice the flowers in order that as long a growing season as possible can be obtained. An item in connection with rhododendron culture which it is as well to note is that the removal of the old flower heads before seeds have time to form is attended with beneficial results.

Bamboos require pruning each spring, and pruning, in their case, takes the form of removing a proportion of the older growths in order that plenty of room for young shoots is found. This thinning out has the effect of keeping the plants open and graceful in outline. It must, however, be observed that it is necessary to remove old shoots right to the base, not leave them six or eight inches long, for such snags seriously interfere with the proper development of the young culms.

W. Dallimore.

Spinach.—Select a warm and sheltered border and make a sowing of the summer variety of spinach, to follow the winter kind. Draw the drills from fifteen to eighteen inches asunder, and sprinkle a quantity of soot on the ground. Thin out the young plants to a foot apart before they become drawn to obtain thick succulent leaves.—C. F.

EARLY-FLOWERING CHRYSANTHEMUMS.

In spite of the fact that the early-flowering chrysanthemums yield their flowers at a time when there is a galaxy of beauty in the garden, and also serve to remind us that the summer is far advanced, they are very welcome, and are of immense value to replace subjects that may have "Ichabod" written upon them.

The accompanying illustration depicts a large bed planted with Goacher's Crimson and Horace Martin, and when it is explained that they were growing in congested Bermondsey (Southwark Park), nothing further need be said as to their value for town gardens.

A GROUP OF EARLY-FLOWERING CHRYSANTHEMUMS, SOUTHWARK PARK.

Few classes of plants are at once more floriferous and accommodating, and the elaborate details, composts, etc., we sometimes read about in connection with their culture is all so much moonshine. Experience shows that to plant in very rich and heavily manured soil is to court comparative failure, and to promote over exuberant growth and consequent paucity of flowers, while on the other hand, if the ground be lightly dressed with short and well-decayed stable manure or leaf-soil, and solidified, a full measure of success is certain.

With respect to propagation, nothing is gained by inserting the cuttings earlier than the end of March, and this season at any rate, thanks to the mild character of the winter, abundance of sturdy rooted plants may be detached from the outer parts of old stools in the garden. These should be put into small pots, and arranged fairly close to the glass in cold frames, preparatory to being planted in permanent quarters about the end of April. An open and sunny position is essential to success, and in the event of long-continued drought the ground should be saturated from time to time. Further, if stopped or pinched twice, we get bushy and symmetrical specimens, and if it is intended to press a number of these plants into service for late summer display in flower beds a colony should be established in the reserve garden. If due care be exercised in lifting and planting, and the plants are watered overhead morning and evening for a few days, no check will be received, and no appreciable difference can be detected as regards their season of beauty from that of pot plants.

Need it be said that these chrysanthemums form delightful pot plants? And in view of the fact that so used we have them under control, a fairly liberal compost may be employed, while the labour involved in artificial watering may be reduced to a minimum by plunging the pots in coal ashes after the final shift. It is superfluous to add that stimulants may be applied with advantage, dating from the time the buds are formed, and, failing animal manure in solution, any approved artificial manure will answer the purpose admirably.

There are a large number of varieties in commerce, and a few reliable sorts for either pots or border are Goacher's Crimson, Vesuve, chestnut-crimson with golden reverse; Harvest Home, Market White, and Mychett White, Doris Peto, and Feu Japonais; Horace Martin, Ethel, Leslie, Elstob Yellow, and Clara are good yellows; Normandie and Provence in pink; Freedom in rosy-purple; Claret, bright claret, with Diana and Ethel Blades, chestnut. The early-flowering single kinds are worth attention.

Walter H. Aggett.

CHRYSANTHEMUMS.—For full instructions on the Culture of Early-flowering Chrysanthemums in beds or borders for garden or greenhouse decoration, read the Second Edition of Chrysanthemums for Garden and Greenhouse, by D. B. Crane, price 2s. 6d. net; or by post, 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

RHODODENDRON PRÆCOX.

This very early-flowering rhododendron brightens up our shrubberies and the rhododendron dell very much thus early in the season. It is an extremely free-flowering shrub, with lilac-purple flowers, and when fully developed a mass of it is very effective. At the end of February we have a great many plants in bloom, and, although we had 8 degrees of frost recently, this does not appear to have damaged them at all. The bushes are very shapely, and flower while in a small state, but when from 3ft. to 6ft. high, they excel, and there is no other shrub so brilliant at this season.

Stock is raised quite easily by layering, and when a plant becomes too tall from age or any other cause, it is quite an easy matter to take it up, plant it obliquely, and layer all the branches. One is thus treated occasionally, and small plants are always available. Rhododendron præcox is the result of a cross between R. dahuricum and R. ciliatum, and most resembles the former. If a little shelter can be afforded it, so much the better; a warm recess, near buildings, or the shelter of larger plants can generally be chosen for such a choice shrub.

W. A. Cook.

Standard Clerodendrons are most effective, but are only produced after two or three years' training. For this purpose cuttings must be put singly in small pots and given every encouragement to grow, by providing ample rooting room, in due course these will produce a stem four to six feet high. The head of the standard, after due stopping, is most easily secured by training the shoots over an umbrella-shaped trellis. For a potting compost use loam and peat in equal parts, with lime rubble and broken charcoal added in sufficient quantities to render the material open and porous.—J. D.

SWEET PEA JOTTINGS.

Sweet peas—purely considered from the seedsman's point of view, are booming this year as they never have boomed before. Stocks of many choice new varieties are already sold out, and still the orders come in. Given good weather from the end of March onward, and a summer that is more like the summer we used to have, sweet peas will achieve a popularity never experienced by any other flower raiser annually from seeds. From my own experience the germination of seeds is particularly good this season, so that the promise is excellent.

In some measure it is unfortunate that we have all gone in so strongly for extremely high culture, because when we talk of trenching the plots three feet deep, and adding cartloads of manure, we rather frighten the man in the street. To obtain the very finest results on the exhibition table great pains must be taken in cultivation, and in raising the seedlings, and, of course, thorough cultivation pays handsomely, even when we consider sweet peas solely for their value in garden decoration and in the home. There is plenty of time yet to sow sweet peas. Sown in pots placed in a cold frame and kept close until the seedlings push through the soil, and then given abundance of air on all favourable occasions, sweet peas come along rapidly, and yet sturdily, at this season of the year, and make capital plants for setting out in early April on the plot where they are to flower.

So much has been said and written about sowing sweet peas in pots to secure strong plants for early planting, that the sowing of seeds out of doors where the flowers are to be produced is being greatly overlooked. We do not care to risk choice and costly varieties by sowing them out of doors, but there are crowds of people whose names are unknown to the enthusiasts, who have no conveniences for raising an early stock, who have an intense love for sweet peas, and who are not desperately anxious to secure the very latest novelties. To these one may suggest that the cheaper varieties may very well be sown, and treated in the same way as culinary peas, except that the seeds should not be so deeply buried, and, to guard against depredations by birds and mice, they should be coated with red lead.

Red-leading is easily managed. Put the seeds in a small tin lid, pour in a little water, and, when the seeds are all moistened, pour off the surplus water. Then dust the seed with a little dry powdered red lead, taking care not to inhale it, and also taking care to use gloves if there are any wounds on one's hands. With a circular motion induce the seeds to roll round and round until each one has a thin coating of red lead; this achieved, let the seeds dry, and when dry sow them about twice as thickly as the plants will be allowed to remain. From now onward right through the month of March, weather permitting, sweet peas may be sown out of doors, and if the ground has been prepared with reasonable care there should be a fine crop of good flowers in due course.

From Helen Lewis, Mrs. Hardcastle Sykes, Clara Curtis, Countess Spencer, Etta Dyke or Nora Unwin, John Ingman, Mrs. C. W. Breadmore or Evelyn Hemus, Constance Oliver, and Asta Ohn or Masterpiece, with one of the crimson varieties, a really excellent selection of six or more sweet peas may be made with the assurance that all are fixed, and that flowers of fine type, giving a good range of colour, will be forthcoming.

Lovers of sweet peas, and those who sell sweet peas, should do all that lies in their power to secure new members of the National Sweet Pea Society. From a business point of view this would be a good move, because the influence and usefulness of the society are great, and increased membership and a strong society are bound to react upon the seed trade by increasing the demand in the immediate future, and by ensuring the popularity of sweet peas for many years to come.

The "Sweet Pea Annual" and schedule, now in the hands of all members of the N.S.P.S., contain rather formidable lists of too-much-alike varieties. No fewer than nine crimson varieties are bracketed together; there are two groups of blush varieties, five in each; there are nine mauve sweet peas, not more than one of which may be shown in a stand at the London show on July 11 and 12 next; of cream-pink varieties there are also nine grouped together as being very like each other; while in the maroon class ten varieties are lumped together as possessing a close resemblance one to the other. Nine seems to be a favourite number in this connection, and we find that number of white varieties, and a similar number of yellow and buff varieties classed as too-much-alike. One turns to the Classification List for help, there to find "an up-to-date selection of varieties in commerce," but one that "does not include novelties first distributed in the autumn of 1910 or spring of 1911." The Classification List is, therefore, an excellent guide for the great body of sweet pea lovers, and they appreciate it.

Chas. H. Curtis.

THE FUTURE OF THE SCOTTISH HORTICULTURAL ASSOCIATION.

(Continued from page 172.)

LOOKING FORWARD.

This concludes my historical references to this subject, which have necessarily been full in order to show those of you whose connection with the association is of somewhat recent date that this question has from the very first been kept in the forefront among the aims and objects of the association, and to show you that what I am about to propose is no innovation, but would merely be the logical outcome of this persistent advocacy. I propose nothing new to you, except that you should exchange a philosophy of words for one of deeds and actions.

It is now nineteen years since Mr. Welsh referred to the formation of a gardeners' institute as being almost within our reach. Three years before that, in 1889, the association had commenced to hold its chrysanthemum shows in the Waverley Market, and, owing to the great success with which these were attended, it may be that the office-bearers and members alike became so obsessed with them that the greater question was completely lost sight of; at any rate, with the exception of the allusion to it by Mr. Todd in his address fourteen years ago, no further reference to it is to be found until four years ago, when it was resuscitated by one of my immediate predecessors in this chair, Mr. D. W. Thomson, who in his presidential address strongly urged the formation of a great horticultural centre for Scotland in this city, and at the present moment an undischarged motion by our friend, Mr. King, to make a commencement by raising a fund for the purpose, stands in our Council minutes.

Well, "Ex nihilo nihil fit" is a classical phrase as trite as it is true. Out of nothing nothing can come, and unless we cease our talk and begin to act we will be no further forward in the next decade than we were in the last, or than we are to-day; if, indeed, we have not retrogressed. Times have changed. There is no reasonable prospect at present of a return to the palmy days of chrysanthemum shows of five to twenty years ago. There is small prospect at present, even with the greatest attractions we can legitimately offer, of drawing £1,200 at the gates, nor of any sum approaching it. In 1908 and 1909 we had a heavy loss. Last year, with a somewhat novel departure in our show procedure, we scraped through with a small surplus, but it was only accomplished by exercising the most rigid economy. The unpleasant fact has to be faced that there is at present a steady decline in the attendances at our shows, and we have no assurance that the decline will not go on. The question, then, comes to be, how far can we go in this direction? There must be a limit to our economy, if there is none to the smallness of our attendances, and if the decline in the latter goes on, what then? I sincerely hope we have reached bed-rock in our attendances, but who can tell? Counter-attractions which ten years ago had no existence, have sprung up—and are still springing up—in all directions. The best military bands can be heard elsewhere in the city almost any season. The Waverley Market, when compared with other up-to-date halls for entertainments, has earned an unenviable notoriety as a kind of refrigerator in the month of November, a fact which cannot be too strongly impressed on the Corporation, to whom the building is a source of very large revenue, most of which is derived from rents for shows and other entertainments.

Flower shows have ceased to attract as they used to do, and as the holding of them was not part of the original work of this association, I think we should pause and reconsider the whole question afresh. As I have said, we cannot hope for an immediate return at present of the palmy days of our chrysanthemum shows of twenty or even five years ago. Our funds are not increasing, but our association is growing, and its work is increasing. But restricted revenue will strangle its efforts to expand. How, then, are we to exist? For years the revenue of the association has not met its expenditure, and the deficit has had to be made up out of show surpluses. But if these, too, are to cease, how is the work to be carried on? It seems to me that we must move, and move at once.

A HORTICULTURAL LIBRARY.

I have already given you a résumé of what has been done since the starting of the association with regard to a library, museum, and reading room, the acquirement of which, according to its original constitution, was one of its principal objects. In the matter of libraries there has been a great change since the association was formed, and we have now in Edinburgh, and many of our other towns, thanks to the munificence of our honoured countryman, Mr. Carnegie, excellent public libraries. In this city, too, we have a museum in connection with the Royal Botanic Garden, and a very excellent botanical collection is now housed in the Royal Scottish Museum; and as the latter institution is open on certain evenings, this collection, being more accessible, is, perhaps, of even greater value to the working gardener than that of the former institution. So far as we are concerned, the formation of a museum seems now not to be so necessary as it formerly was—if it is necessary at all—but it is otherwise with a library. The public libraries are intended chiefly to supply the wants of the great general reading public, and for purposes of reference; but sectional libraries, it seems to me, in these days of technical training, are more urgently required than ever, for the literature on specific subjects is vast, compared with what it used to be. One could not expect to find in, say, the Edinburgh Public Library all the weekly and monthly and other horticultural papers and magazines, but that is what our young men require, and it goes without saying that a reading room is necessary where such literature is provided. This, then, was what was aimed at in the original constitution. In the revised constitution of 1908 the words "Horticultural Institution" are used, and this embraces all that was stipulated for in the original constitution, and more, if necessary. As for the starting of a journal, this, I think, however much the want might be felt at the time the demand was made for it, is in these days unnecessary. But there is no reason why our "Transactions" should not be improved, more especially as they are the only medium by which members living in distant parts of the country are kept in touch with the centre. Not only should they contain the papers read at the meetings, and the proceedings thereat, but they should be made a medium of reference to papers, etc., of outstanding importance published elsewhere, so that the members may know where to lay their hands on what they want.

FINANCES OF THE ASSOCIATION.

Having said so much about the attainment of one of its objects, I now wish to glance at the financial working of the association. As I have already mentioned, the ordinary revenue of the association does not meet its expenditure, and any deficit there is has to be made up out of flower show surpluses. But if there is a loss on the show, as there was in 1908 and 1909, it means that this, plus the deficit on the association account, has to be taken out of the funds. Now this, I think you will admit, is not only unsatisfactory—it is very bad finance. The association ought to, and must, be self-supporting if it is to go on progressing, and should be quite independent of show surpluses, and, of course, it follows that it should not be involved in losses on the show. How is this to be done? Well, I think that show surpluses should be carried to a reserve fund to provide against losses on the show when these occur, and the revenue of the association from members' subscriptions and interest on its investments should be so adjusted as to cover its expenditure. But it is quite apparent to me that it is impossible to make ends meet in the association account on the present basis of a £2 2s. life membership subscription, and an ordinary annual subscription of 2s. 6d. At the rate of interest we at present receive on our invested funds (and it is likely to decrease when we realise the major portion of our stocks and invest them in trust securities), we are getting about 1s. 6d. yearly out of every life member's subscription, and out of this we are paying 1s. in actual cash for the publications they receive, and the postage of them, leaving 6d. as the price of the season ticket which they get for the show, and to help to cover the working expenses of the association. We are in a little better position as regards the ordinary members, for, allowing the same out of pocket expenses in their case (it is a little more), there remains 1s. 6d. as the price of the show ticket, and the covering of the working expenses of the association, but this is too favourable a statement of their case, for it takes no account of expense connected with members who fall into arrear, which has to be met. According to our method of accounting, the show is not credited with any portion of the interest on the life members' subscriptions, or of the ordinary members' annual subscriptions as the price of admission; if it were, how long would it take to exhaust the life members' subscriptions? And where would the revenue from ordinary subscriptions in the association account be? I put the question to any business man present, Is this good finance?

Now, my proposal—there is nothing alarming about it—is that there should be a graduated scale from, say, £2 2s. downwards to 2s. 6d. in the annual subscriptions, but that none but under-gardeners or other horticultural employees, should be admitted at the lowest figure. I recognise, however, that it might be somewhat unfair to compulsorily raise the subscription in the case of the present members, and I would suggest that they should have the option to continue on the present basis, but that anyone resigning or lapsing would be required to pay on the new scale on rejoining. Only in this way do I think it possible to put the finances of the association on a sound basis, and I appeal to you to give the matter your earnest consideration in the best interests of the association, the welfare of which I am sure you all have at heart.

(To be continued.)

Pear Marie Louise d'Uccle.—I planted a number of cordons of this variety some years ago, and trained them to the front portion of huge buttresses which supported garden walls twelve and fifteen feet high. In front of some of the walls herbaceous plants were grown, other borders being devoted to vegetables of dwarf growth, salads, and herbs. The pear trees made strong growth from the first, and their roots were equally healthy. Some root pruning was done, but when the borders in front were trenched every autumn I had all roots found beyond a certain line cut off; and in a few years' time we found a mass of fibrous roots growing at the edge of the trench portion of the border, and they received much nourishment from the manure put in for the benefit of other crops. The trees proved very remunerative, bearing heavy crops of extra-large pears, which coloured well in these favoured positions. The variety is a free bearer in ordinary circumstances, but when grown as cordons, duly root-pruned, and well fed, the trees respond handsomely.—Geo. Garner.

AILSA CRAIG ONION.

A DOZEN FINE SPECIMENS OF AILSA CRAIG ONION.

When a true and reliable stock of the well known and popular Ailsa Craig onion is cultivated it is highly esteemed, not only for its value as an exhibition variety, but also for general purposes. When cooked whole it stands unrivalled, and, in my opinion, is in every way superior to imported onions. It is of the utmost importance that the best possible strain be secured, and there is yet much to learn in the selection and re-selection of the bulbs.

To obtain specimens of large size and good quality it is necessary to allow a long season of growth, and the seeds should be raised in a gentle heat during the month of January in shallow boxes, and the seedlings pricked off when large enough, allowing sufficient room for the young plants to develop, and to ensure sufficient space for lifting when the planting season comes round. The young onions should be grown in a gentle heat in the lightest place available to ensure a sturdy growth. Gradually harden them off in cold frames before planting out in the permanent quarters.

No crop pays for good cultivation more than this. The ground should be deeply trenched and heavily manured during the winter months, and forked over and made fine just prior to planting, which should be accomplished during good weather in April. Nothing is gained by overcrowding; allow at least fifteen inches between the rows and a foot from plant to plant. Make the soil very fine, and apply plenty of water during drought, and also occasional drenchings of well-diluted farmyard sewage. The surface soil should be frequently stirred with the Dutch hoe, and during showery weather light applications, at frequent intervals, of a patent vegetable manure and soot should be given.

To ensure their keeping satisfactorily the bulbs should be lifted immediately they have matured, removing all loose skins, and using the utmost care to prevent bruises. Onions may be cultivated on the same site for many years.

E. Beckett, V.M.H.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

EAST INDIAN ORCHIDS. — Vandas, ærides, saccolabiums, and allied genera, will now be showing signs of renewed vitality: the points of the roots are becoming green, and the new growth and flower scapes will also soon be prominent. In the case of vandas of the V. tricolor section, the plants often lose some of their basal leaves during the autumn and winter months, and where they have become leggy they should be turned carefully out of their pots, the old compost removed, and the bare basal stems be cut asunder with a sharp knife at the most convenient point, which will have to be governed by the situation of the roots on the stem. This shortening will serve to bring the lower leaves nearer the pot, and will ensure a better appearance when the plants are repotted. The size of the pots used must also be governed by the number of stems or plants placed in them, but before repotting each stem should be secured to a stake or cane sufficiently strong to hold it in position.

POTTING.—Place a suitable crock over the hole at the bottom of the pot. The plant should then be placed in position, and the crocks and potting compost worked in, placing as many roots as may be desirable inside the pot as potting proceeds. Chopped sphagnum moss is all the compost required, working it in with plenty of broken crocks to afford free drainage. It is not so much the potting compost used, but the holding of the plants firmly in position that is desirable. After potting, more will depend on the atmospheric conditions provided for the plants than anything else. If a warm, close, humid atmosphere is provided there is little difficulty found in the successful cultivation of vandas, etc. Being purely epiphytal they derive most of their sustenance from the atmosphere, and unless the conditions are suitable it is only a waste of time to attempt to grow them. The temperature of the East Indian house from the present time should not be allowed to fall below 70 degrees at night, with a rise of five to ten degrees according to the outside conditions during the daytime. Shade carefully for a time after potting, but as soon as the plants have become established in their new material more light may be afforded, and the blinds should be drawn from the roof early in the afternoon, so that the sun may assist in raising the temperature and reducing the atmospheric moisture before the cooler evening temperatures are reached.

VANDAS.—It is a great pity that vandas have not been so extensively grown during late years, and it should not be overlooked by those who grow orchids for exhibition purposes that a finely-grown and flowered plant of the V. tricolor section is a most attractive subject in a group of orchids. The smaller-growing vandas, such as V. Kimballiana and V. Amesiana, are best grown in shallow pans or baskets, so that they may be suspended near the roof. They require but little disturbing, so that when potting is done the compost should be of a lasting nature. About equal proportions of fibrous peat, osmunda fibre, and sphagnum moss is generally found suitable.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

MALMAISON CARNATIONS.—The earliest plants are now showing their flower spikes, and will benefit by an application of an approved fertiliser, as well as occasional waterings with soot water. Damp the stages slightly on bright, warm days to prevent attacks from insect pests. On all occasions keep up a free circulation of air by means of the ventilators; even at night the house must not be closed down, as a close atmosphere is very detrimental to the well-being of Malmaisons. Plants from last year's layers, which are now in 32 and 48-sized pots, must have attention given to staking; one neat stake in the centre will be all that is necessary.

FUCHSIAS.—Old plants that have been rested throughout the winter months may now be brought forward and prepared for starting into growth If an increase of stock is necessary, a few may be placed in a brisk heat to produce cuttings. They will require very little pruning, merely removing the tips of the growths. Plants required for specimens should be pruned hard back, and made shapely. Shake away the major portion of the old soil, and repot in good fibrous loam, leaf-soil, and sand, to which may be added some rough charcoal. An early fruit house is a good place in which to stand fuchsias, where they may receive frequent syringings. Water sparingly until growth has commenced.

PROPAGATION of the various plants for winter flowering must now be taken in hand. In the case of libonias and bouvardias these should be cut back, using the tops for cuttings. Reduce the ball of the old plant and repot, using as small a pot as possible. Take cuttings of heliotropiums, Salvia splendens, marguerites, and other plants for summer and autumn flowering. Where a special strain of coleus is kept, these may also be propagated. It is advisable to make a sowing of mixed coleus seeds, as the many different colours thus obtained make a charming display, and often a variety of especial merit is found.

BASKETS FOR CONSERVATORY.—Well-furnished baskets suspended from the roof produce a delightful effect in the conservatory. Asparagus Sprengeri and the different varieties of nephrolepis are very suitable for this kind of decoration. These should be planted in the baskets at once, and suspended in a warm house to encourage new growth before being taken into the conservatory. Another very suitable plant for baskets is the beautiful Lobelia tenuior, its long trails of fine blue and white flowers making it very attractive. It may also be grown in small pots for edging. Seeds should be sown now.—A. Grubb, Porter's Park Gardens.

HARDY FRUITS.

PEACHES.—A cortinuance of unusually mild weather is beginning to tell on the wall fruit. Peaches and nectarines should, of course, be pruned after all fruit is gathered in the autumn, but even then there will still remain a certain amount of surplus wood, which should be cut out with a grim determination to have the growth well thinned, or a lot of time will be wasted in disbudding and thinning of fruits at the most busy time of the year.

WASHING WALL FRUITS.—A good soap and sulphur wash should be given to all stone fruit after the tying or nailing is finished, using about 2oz. of soft soap, and one large handful of sulphur (the sulphur made into a paste with a little water) to one gallon of hot water, as hot as can be used with an ordinary syringe; thoroughly wet all the wood, and driving the moisture with force into cracks and crevices of the walls. This will act as a preventive of aphis and red spider during the earlier time of growth.

MORELLO CHERRIES.—These should receive attention as soon as time will allow: all old shreds and nails should be removed, and, if laid in a small heap, with a little paraffin poured over them, and burnt, many of the nails will be found suitable for use again. Morello cherry trees should be treated somewhat the same as peaches, tying or nailing in the full length of fruiting wood, but avoiding overcrowding, otherwise small and stony fruits will be the result.

WIRING FRUIT WALLS.—Stone fruits will receive many benefits if accommodated on wires set two or three inches from the walls, with, perhaps, the exception of Morello cherries. These, in my opinion, being the only stone fruit adapted to the nailing system, all others, either through habit of growth or mode of fruiting, receiving more or less injury because their fruits come into contact with the nails. Given a quantity of wire, a few strainers, and eyes, any wall may be set in order for a lifetime by a few hours activity, and the cost of the material is soon saved in the quality of the fruit, not to mention the prevention of injury to walls.

A GOOD KEEPING PEAR.—The most useful pear fit for dessert at the present time is Duchess de Bordeaux. Trees of this variety are very hardy, but, like other pears, better results are obtained if a position on a wall can be given, as it is slow to make growth in the open. The fruits are melting, and of excellent quality, and quite unlike others for keeping well after ripe; the season is from late January until the end of March. The size is medium to large, if reasonably thinned; it is a regular cropper, and altogether an excellent pear.—J. Whittle, Cheveney Gardens.

THE KITCHEN GARDEN.

CARROTS.—Make a sowing of the French Shorthorn type on a rather high and warm south border to follow the forced crops. If the seeds are sown somewhat thicker than is usual with the main sowings the larger roots can be selected at each pulling, and so give a lengthy supply. Draw drills from twelve to fifteen inches apart, and if wireworms are troublesome spread soot along the drills before closing them in.

EARLY POTATOES.—Especially in the northern counties, those who are fortunate enough to possess plenty of rough frames for early vegetable culture have excellent opportunities. A quantity of tubers may be planted under these protections to succeed the forced ones, while any narrow south border may be planted with early varieties. These positions can be afforded coverings as necessary on frosty nights at little time and expense for a few weeks until the crop is safe. May Queen, Field's Seedling, or any of the short-topped kidneys, are suitable for this planting. If the ground is light give a dressing of bonemeal and wood ashes along the trench with the tubers.

TOMATOES.—A sowing of seed should be made to provide plants for the principal crop inside, and also for well-established plants with a truss or two of flower upon them for planting outside against walls, or other shelters, in May or early in June. There are many good varieties, but one cannot make a mistake in including Sunrise and Moneymaker in the list. Pot the early plants as they require it, but leave room in the fruiting pots for top-dressing of soil, etc., to assist the plants when they are in full bearing.

TRIPOLI ONIONS.—Whenever the ground can be found in good order for planting make a good bed of these onions, to give a supply until the spring-sown ones are ready for use. Plant firmly, and on some soils a watering may be necessary. About fifteen inches from row to row, and from ten to twelve inches from plant to plant in the row, is sufficient space for them.

CELERY.—The main crop should now be put in. Sow again a fortnight later for supplying plants to succeed these.

TURNIPS.—Make a small sowing of early turnips, such as Milan. These are liable to run to seed, consequently it is preferable to make fortnightly sowings to avoid waste. The autumn-sown bulbs, unless turnip tops are appreciated, may now be pulled and stored in sand in the root house, and the site manured and dug for future cropping.

GENERAL REMARKS.—The greater part of the wheeling of manure, etc., and the rough work on the quarters should by this be near completion. The edgings may now be put in order, where necessary, either by replanting or straightening them, as the case may be. The walks may then be regravelled, or turned and rolled, so as to give the kitchen garden a neat and pleasing appearance. Reduce shelter to plants as far as it is safe to do so as the month advances. Remove old cabbage and broccoli plants as soon as the tops are cut, and deal with arrears of work actively, to give as much time to the sowing and attention of young crops as possible.—C. Flack, Cholmondeley Castle Gardens.

THE LIVERPOOL HORTICULTURAL ASSOCIATION.
SPRING BULB, ETC., SHOW, April 5th and 6th, 1911.
Prize Money, £82.
SWEET PEA, ROSE, CARNATION, ETC., SHOW. July 19th, 1911.
Prize Money £44 and Five Guinea Silver Bowl.
AUTUMN CHRYSANTHEMUM, ETC., SHOW. November 8th and 9th, 1911.
Prize Money £112, and Twenty Guinea Silver Challenge Cup.
The above Shows will be held in the CORN EXCHANGE, BRUNSWICK STREET, LIVERPOOL. Particulars and Schedules from Secretary, HAROLD SADLER (Finney, Son, and Sadler), Chartered Accountant, 31, North John Street, Liverpool. Telephone: Bank 3,957. Telegrams, "Abatement."

WOLVERHAMPTON
GREAT FLORAL FETE.
July 11, 12, and 13, 1911.
£900 IN PRIZES.
Schedules on application to the Secretary.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, FEBRUARY 28.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair), Sir Everard im Thurn, Sir John Llewelyn, Rev. Canon Fowler, Prof. Boulger, Messrs. E. H. Holmes, A. Worsley, J. T. Bennett-Poë, J. Fraser, H. J. Elwes, R. Hooper Pearson, W. C. Worsdell, W. Hales, J. W. Odell, and F. J. Chittenden (hon. secretary).

GALANTHUS HYBRID (?).—Mr. Bowles showed drawings of the galanthus exhibited by Mr. Elwes at the last meeting, and reported that in structure and appearance it approached certain hybrids of G. Elwesi. He thought it might be a hybrid of that species with G. caucasicus, but the characters shown by seedlings which Mr. Elwes said would probably flower next year would throw further light upon the parentage. Mr. Elwes showed a photograph of a group of the form growing in his garden.

HIPPEASTRUM CALYPTRATUM.—Mr. Worsley showed flowers of the unspotted form of this species from his garden.

LOPEZIA RACEMOSA.—Mr. Odell showed flowering shoots of this plant, and commented upon the peculiar method of pollination.

GALL ON WILLOW.—Mr. Fraser brought stem galls upon Salix purpurea Lambertiana similar in appearance and structure to those produced on S. aurita, etc., by the dipteron Cecidiomyia salicis, which he thought had probably been formed by that insect, although they were usually found attacking only sallows.

HYBRID HIPPEASTRUM.—Mr. Elwes showed flowers from plants the result of a cross between Hippeastrum equestre and H. x Sir William The plants flowered at two years of age, and bore red flowers (as usual with equestre crosses), varying, however, in shade and markings. Mr. Elwes undertook to report later upon these hybrids when more plants from the same cross had flowered.

FASCIATED ORCHID.—Mr. Gurney Wilson showed a plant of Brasso-catt-lælia x Fowleri, on which one of the pseudo-bulbs had forked before flowering, and both forks appeared likely to flower. Mr. Wilson remarked that malformations of plant and flower appeared to be much more frequent in trigeneric hybrids than in the species.

NARCISSUS CYCLAMINEUS x N. MINIMUS.—Mr. Bowles showed a plant of this cross raised by Mr. Chapman.

SAXIFRAGA x BURSICULATA.—A hybrid between Saxifraga Burseriana and S. apiculata, came from Mr. E. H. Jenkins. The plant was remarkably vigorous and free flowering. In the length of the peduncle, its greenish colour, and in the form of the calyx, the hybrid resembled S. apiculata. The whiteness of the corolla and the crimped edges of the petals called to mind S. Burseriana, as do the spiny and glaucous characters of the foliage. In the size of the rosettes and the horizontal spreading of the leaves it resembles S. apiculata. The other seedlings raised from the same capsule included two yellows, one poor and weedy looking, and ten plants indistinguishable from S. Burseriana.

BEETLE BORING BARK OF AUSTRIAN PINE.—Canon Ellacombe sent a piece of the bark of Pinus austriaca bored by a beetle, which Canon Fowler reports upon as follows: "The borings of the beetle in the bark of the Austrian pine are very old, and there is no trace of either beetle or larva to be found. I think it, however, probable that the injury was done by Hybastes ater, which attacks various kinds of pine, both roots and trunk; it is a rather common and widely distributed insect in England, but apparently commoner in Scotland. This is, however, surmise, as it is impossible to be certain; the wood looked as if it had been used for a pergola or fence of some sort, and was quite dry and ancient."

DOUBLE ARUM.—Miss Musgrave, of 63, Cadogan Gardens, S.W., sent a specimen of Richardia africana having the leaf next to the inflorescence wholly white, except for a slight green mottling. Miss Musgrave said that the same plant had produced similar growths in former years, and that each shoot upon it behaved in the same way.

FASCIATION IN PRIMULA MALACOIDES.—The Venerable Archdeacon Donne sent a water-colour drawing of Primula malacoides with a fasciated stem.

Ladies' Bulb Show in Dundee.

This most interesting annual exhibition was held on the 28th ult., when the Drill Hall presented a beautiful and spring-like appearance. The bulbs shown on this occasion were chiefly hyacinths and narcissi, and were grown in ornamental bowls amongst stones, and tended by the lady exhibitors through all the stages of development in rooms, without greenhouse or conservatory aid, and the degree of perfection under such conditions that was noticeable in each exhibit was a revelation to many who had not yet attempted this interesting method of growing spring flowers. Beyond the interest of the occupation and the wholesome rivalry for the first prize, there still exists a laudable object, viz., to bring a day of spring fragrance and beauty to the lives of the patients in the Royal Infirmary, to which the exhibits were all consigned at the close of the show. For the most part competitors are restricted to one, six, seven, nine, and twelve bulbs of certain varieties in each bowl, and in each class a first, or a first and second prize are offered, competent gardeners acting as adjudicators. The example set at Dundee might be imitated by other cities and towns with very pleasant results.

Quite a large crowd assembled at the opening, when Mr. R. B. Don presented the prizes to the winning ladies, tea being afterwards served by Mrs. Howard Hill and Mrs. R. L. Watson.

Gardeners' Royal Benevolent Institution.

The Liverpool Auxiliary achieved a great success at their tenth annual concert, held at the Bear's Paw, on the 3rd inst. These successful gatherings do much to keep the institution in touch with the gardening fraternity in the district, and on this occasion, when Mr. Harry J. Veitch, V.M.H., and Mr. G. J. Ingram accepted the invitation, special efforts were made to ensure the event being a memorable one. Mr. Allan H. Bright, J.P., tendered to the London visitors a generous hospitality during their visit to Liverpool, and Messrs. N. F. Barnes, J. J. Guttridge, H. Middlehurst, the committee, and officers were invited to meet them at dinner at the Reform Club previous to the concert. After the patriotic toasts the host referred in sympathetic terms to the absence of the esteemed chairman of the Liverpool Auxiliary owing to the loss of his wife after a long and painful illness.

The large audience gave evidence of their appreciation of the visit of the chairman and secretary of the Gardeners' Royal Benevolent Institution by a great ovation on their entry to the large hall. The decorations, as usual, were ably carried out by the generous help of Messrs. R. P. Ker and Sons, W. Rowlands, B. Webb and Sons, C. A. Young, and others, who provided well-grown plants and cut flowers, and to a member of the committee for buttonholes for the chairman's table.

During the evening Mr. Veitch delivered an admirable address on the objects and work of the institution, and spoke appreciatively of the assistance rendered by the Liverpool auxiliary, which materially helped the London committee in granting help to the needy. On the motion of Mr. Allan H. Bright, seconded by the Auxiliary's secretary, a vote of thanks, accompanied by musical honours, were accorded to Mr. Veitch and Mr. Ingram for their visit and addresses.

The officers of the society, Mr. C. A. Young, chairman; Mr. J. Finnigan, vice-chairman; Mr. A. J. Crippin, treasurer; and Mr. R. G. Waterman are deserving of much credit for their successful efforts.

National Hardy Plant Society.

A meeting of the council of this society was held at the Hotel Windsor, on February 28. The Executive Committee reported that they had been in communication with various societies, and were co-operating with York Gala, Cardiff, and Leamington, and they hoped to co-operate with the new North of England Horticultural Society. They recommend that the GARDENERS' MAGAZINE gold medal and £3 cash be offered as a first prize, a silver-gilt Coronation medal and £2 as second prize, and £1 as third prize, for a special class for an exhibit of hardy plants of not more than three kinds, arranged in

Eckford's
Giant SWEET PEAS

The Finest Blooms

that blossom on the Sweet Pea Plant are grown from Eckford's famous seeds. Eckford, the Sweet Pea Specialist, supplies only seeds that are bound to give good results. Eckford's seeds flower brilliantly, give brighter colours, longer stems, larger flowers, and succeed even in the most difficult soils.

ECKFORD'S are the largest retailers of Sweet Peas in the world, and do not supply the trade.

Villa (B) Collection.
24 Splendid varieties, suitable for exhibition, 50 seeds of each, **5/6**, post free for cash.

Villa (C) Collection.
12 Splendid varieties, suitable for exhibition, 50 seeds of each, **2/9**, post free for cash.

Villa (E) Collection.
12 Extra varieties, suitable for exhibition, 25 seeds of each, **1/6**, post free for cash.

A specially written Booklet on Sweet Pea Growing given with every order.

For full list of Special Novelties see next week's issue.

FREE. Send a postcard to-day for large Illustrated and Coloured Catalogue. It gives full particulars of all novelties in Sweet Peas for 1911, and contains full list of all flower and vegetable seeds.

HENRY ECKFORD, F.R.H.S.
(Dept. 221), Wem, Shropshire.

the form of a circular bed upon ground space of not less than six feet, and not more than eight feet in diameter, to demonstrate the value of herbaceous plants for bedding purposes; an edging of some other hardy plant may, at the discretion of the exhibitor, be used to heighten effect. They recommend also a silver-gilt Coronation medal for the best exhibit of alpines at the June show of the North of England Horticultural Society, if arranged; and that a silver-gilt Coronation medal be offered to the Cardiff Society for the best exhibit of hardy plants or flowers in the show, to be awarded by a deputation appointed to attend.

The report was adopted. A model schedule was considered, and it was decided to take the views of the members of the council not present before settling same.

It was resolved to issue a special circular appealing for members. Designs were submitted for the First Class Certificates and Certificates of Merit, which were adopted.

Mr. Gill, of Penryn and Falmouth, exhibited a new hardy primula (Primula Winteri), from the Himalayan Mountains snowline, 12,000 feet elevation. The species has only been seen previously in herbarium specimens, which were sent over to this country some forty years ago. It will prove a great acquisition to the growers of alpines, and was awarded a First Class Certificate.

The question of pansies and violas was discussed, and it was decided to have a good exhibit of new varieties at a future meeting, and to add a specialist to serve on the council to look after their interests.

A vote of thanks was unanimously accorded the donor of the three silver-gilt Coronation medals.

Leeds Professional Gardeners.

The members of this horticultural society recently held their forty-fourth annual dinner at the Green Dragon Hotel, Leeds. Alderman W. Penrose-Green presided, and was supported by Councillor Leslie Owen in the vice-chair. There was an excellent attendance, and the Chairman referred to the long association of his firm with the society, so long that he felt honoured to continue that support by presiding on this their annual dinner.

The Chairman of the City Parks Committee, Councillor Leslie Owen, in proposing "The Leeds Gardeners' Lodge," referred to the fact that horticulture did not obtain assistance from educational centres such as the gardener could avail himself of, and he heartily congratulated the society upon its very low management expenses. He humorously remarked, viewing the balance-sheet, that the only fault he could find was a vacant space, which he hoped would be filled by honorary members ere long. Mr. Donoghue, responding as the society's president, briefly referred to its progress and difficulties during its earlier history. Unfortunately a great many gardeners gave their sympathy, but when invited to join remarked they would "Wait and see." He never knew anyone get much out of a business until first some money was paid into it. The society, since its inception, had distributed over £3,000 amongst those in need of such assistance. They had much to feel grateful for, as they had benefited from honorary members to the extent of nearly £700, which was a valuable asset to the society, and carried with it no liabilities. He heartily thanked Councillor Owen for his remarks, which, he felt confident, would stimulate members to increase their numbers. To the horticultural Press, which had afforded much valuable assistance by publishing annual reports, he also tendered hearty thanks.

The Rev. Bernard Hall, as representing the North of England Horticultural Society, referred to the necessity for organisation for all branches of horticulture. The Leeds Lodge, amongst others, would, he hoped, entertain a mutual understanding with the N.E.H.S. Referring to the recent appointment by the London County Council of an army officer as their chief of parks, he said that had any sufficiently well-organised body of horticulturists been in existence such an injustice might have been prevented.

Mr. G. W. Jessop, in a few well-chosen remarks, proposed the toast of "Gardeners and Gardening." The society's energetic secretary, Mr. George Carver, was paid a high tribute for the efficient and unselfish work which at all times he has given to the society. It was stated that Mr. John Franklin would this year complete his twenty-one years' service to the lodge as treasurer.

The Professional Gardeners' Society is now an Oddfellows' Lodge. Its income for the year 1910 was £231 4s. 4d., and expenditure £138 4s. 8d. The accumulated funds amount to £1,765 19s. 1½d., of which £1,700 is invested in Leeds Corporation Stock.

Croydon Gardeners' Society.

A lecture on "Pretty Gardens and Flowers" was delivered at the recent meeting of the above society, when the attractiveness of illustrated lectures was again shown by the big attendance at the Sunflower Temperance Hotel, every seat being occupied.

The lecturer, Mr. M. E. Mills, Coombe House Gardens, displayed a capital series of lantern slides, many of them being made from photographs taken by himself. The views were very varied, some being of local gardens and specimen plants found therein. The Royal Gardens, Kew, and the Wisley Gardens of the Royal Horticultural Society also furnished pictures beautiful and impressive. To the gardener these views serve a double purpose, for they are not only a source of recreation, but they serve as a copy in remodelling or improving gardens under their charge. Cultural directions were given, and were listened to with great interest. The art of photography is closely associated with the gardener's life, and he cannot do better than take it up as a hobby, for he is oftentimes the observer of Nature's best pictures, and, being able to record the beauty of these scenes, they serve him in after years, reminding him of the many details connected with it, whether in planning a new garden or reviving the culture of a plant under his charge. Mr. Mills appears to be a student ever mindful of this, and in the gardens at Coombe House he finds plenty of subjects to work upon.

Another item of great interest at this meeting was the portrayal of colour photography undertaken by one of the society's vice-presidents, Mr. J. Noaks. Although an amateur in this work, he showed a dozen or more unique slides from his own photographs, recently taken. The colours were easily distinguished, and one could imagine the real flower border or group of flowering plants in all its glory.

With such an educative and pleasing entertainment the evening was well spent, and the members were unanimous in their praise of the views and cultural instructions so ably given by the lecturer.

Mr. R. Cleveland received a vote of thanks for an exhibit of grafted fruit trees in pots.

Woolton Gardeners' Society.

A meeting of this society was held at the Mechanics' Institute on the 2nd inst., Mr. G. Haigh being voted to the chair.

Mr. Charles G. Girdham, of Hale, selected "Ornamental Plants" for his subject, and this he treated throughout in a most able manner. In dealing with so large a subject the lecturer went out of the beaten track, giving his hearers the credit of knowing the leading requirements of most of the plants, and confining his remarks to those special needs, which, if observed, lead to success, such as the special seasons for transplanting and for pruning.

As usual, questions were asked, which brought out further information of a practical character. A hearty vote of thanks was accorded to Mr. Girdham for his able address.

ANSWERS TO CORRESPONDENTS.

◆

PLANTING SWEET PEAS.—S. B., Colchester: Assuming that you refer to sweet peas raised in pots, and duly hardened in a cold frame, then the first week in April is about the best time for planting the seedlings where they are to grow and bloom. Attention must be paid to the weather, and planting should be deferred a few days if the soil is wet and the weather very cold.

DOUBLE STANDARDS IN SWEET PEAS.—M. E. J., Elstree: We have already pointed out that at the Sweet Pea Conference, held in London last December, the experts defeated a proposal to regard double standards as a defect. A good many present at the Conference did not vote upon the subject, but of those who did vote there were twenty-five for the proposal and thirty against it, hence, if regard is paid to this finding, then double standards will not be regarded with disfavour at the exhibitions of the present year. We may again point out that while, from an exhibitor's and from a florist's point of view, flowers with double standards may not be always regarded with favour, there appears to be a very strong opinion in their favour when considered from the market grower's point of view, the idea being that flowers with double standards will look better when bunched, and last longer than those with but one standard.

TRIMMING IVY ON WALLS.—J. W. G., Derby: You should proceed at once to make the ivy quite tidy, and this may be done in either of two ways. One plan is merely to cut back closely all the shoots that stand out from the wall, and all that have grown up close to the gutters and window frames. Another plan is to closely clip all the leaves and growths hard back to the stems that cling to the wall, following the clipping (with hedge shears) with a good brushing of the whole surface to dislodge dead leaves, birds' nests, and any accumulated rubbish. The chief objection to this method is that the walls look bare, and the stems of the ivy rather ugly for a few weeks, but this is compensated for by the knowledge that everything has been spring cleaned, while the new leaves that presently develop have a delightful appearance; such is never seen when they appear amid the older foliage. No harm appears to result from this drastic method, at least not to old-established ivy, and we have in mind a very pretty house, where it has been carried out annually for thirty years, and where, so far as one can judge, another thirty years of similar annual treatment in March, will do the ivy no harm.

SHALLOTS.—M. C. W., Bury: Planting should be no longer delayed. If the ground was well worked and manured last autumn then it should be broken down, made fine on the surface, and raked level at once, weather permitting. Set out the rows one foot apart, and put the bulbs about ten inches apart in the rows, simply pressing them into the soil to two-thirds of their depth. No attention will be needed afterwards other than hoeing, and if the plantation is made in a warm position the crop will be ready to harvest by the end of June or early in July. If extra fine produce is desired then mulch the bed with half-decayed manure when vigorous growth has commenced.

OUTDOOR FIGS.—B. H., Salisbury: Remove the protecting material and fasten the branches into position. Keep a mat or two handy, so that a little necessary protection may be afforded should cold weather return.

INSECT-INFESTED SEEDS.—F. E. L., Lincs.: Probably the method advocated by the Board of Agriculture for killing insect life in grain would serve for seed generally. It is given as follows: "Fumigation with bisulphide of carbon is a very satisfactory way of ridding grain of the insects. The grain to be treated should be put in a bin

"My gardener is delighted with Vaporite, it kills insects very quickly. The land here is very light, and infested with wireworms."
Mrs. E. A. G., Notts.

Carrots, Onions, Potatoes.

"I find after using Vaporite in the garden I had a much better lot of carrots, also onions, and the potatoes were much better." T. C., Staffs.

VAPORITE ENSURES HEALTHY PLANTS & VEGETABLES

To obtain clean and healthy plants and vegetables apply Vaporite to your Garden, NOW, when digging (1 lb. to 8 square yards). By doing this you ensure having the soil free of wireworms, leatherjackets, etc., before planting. Soil insects do far more damage to plant life than most gardeners realize, until they have seen the great improvement after using Vaporite.

or air-tight receptacle, and the bisulphide of carbon poured into a saucer or shallow vessel and laid on the top of the grain. The liquid quickly volatilises, and the fumes, being heavier than air, sink down through the grain and kill all insect life; 1lb. of bisulphide of carbon is sufficient for 100 bushels of grain. The air-tight receptable should be kept closed for 24 to 48 hours. A shorter time would do for small quantities of grain. In treating a store or mill, 1lb. of bisulphide of carbon is sufficient for every 1,000 cubic feet of space. Before entering the mill after such fumigation the doors and windows must be thrown open for an hour or two in order that the place may be well ventilated. If necessary a second fumigation might follow the first. Bisulphide of carbon has a very disagreeable odour, and as the fumes are poisonous they should not be breathed, though a little will do no harm. It is also explosive, and must be handled with care. No naked light should be brought near it, nor should the operator smoke."

SWEET PEAS AND THEIR CULTIVATION.—S. E. G., Bedford: Yes, there was a slight error in the announcement on p. 160, concerning "Sweet Peas and Their Cultivation," by C. H. Curtis. A new and third edition was published in 1910, and this, in addition to being up-to-date, both as regards cultural methods and the selection of varieties, is more comprehensive in scope. You could not possibly have a more trustworthy guide to the cultivation and exhibition of sweet peas, and as an aid in the winning of prizes for these fragrant flowers it will be found invaluable. The book can be obtained from the publishers, Messrs. W. H. and L. Collingridge, 148 and 149, Aldersgate Street, E.C., for 1s. 2d., post free; or for 1s. 8d., post free, bound in cloth.

NAMES OF PLANTS.

M. S., Windsor.—Callicarpa purpurea.

P. B., Chertsey.—1, Anemone hepatica; 2, Adonis amurensis.

D. F. J., Plymouth.—1, Dendrobium Wardianum; 2, D. nobile; 3, Cypripedium aureum.

S. V. P., Cromer.—1, Cypripedium Calypso; 2, Odontoglossum Warnhamense; 3, Epiphronitis Veitchi.

H. N. O., Lincoln.—1, Rhododendron præcox; 2, Cornus mas; 3, Erica carnea; 4, Iris stylosa.

H. C. C., Wrexham.—1, Coleus thyrsoideus; 2, Spiræa confusa; 3, a spray of Ribes sanguinea; 4, Primula frondosa.

G. M. K., Harrow.—1, Daphne indica rubra; 2, Azalea amœna Hexe; 3, Begonia Saturne; 4, Boronia megastigma.

M. H. S., Blackwater.—The heath is probably Erica carnea; the other specimen we do not recognise, please send when in flower.

S. C., Malpas.—1, Saxifraga apiculata; 2, Gaultheria procumbens; 3, Pinus strobus; 4, Thuia obtusa; 5, Adiantum Williamsi; 6, Doodia aspera.

OBITUARY.

◆

MR. ARTHUR RAWLINGS.

We regret to learn of the death of Mr. Arthur Rawlings, late of the Dahlia Nurseries, Romford, who passed away after a short illness on February 14, at Grand Forks, British Columbia, in his fifty-fourth year. After the death of his partner, Mr. John Rawlings, who died in June, 1890, Mr. Arthur Rawlings lost interest in the business at Romford, and, like his father, the late Mr. George Rawlings, he did not take kindly to cactus and decorative dahlias, and somewhat resented the high place these were taking in the floricultural world. In the autumn of 1900 he went out to British Columbia, and embarked in fruit growing, but, unfortunately he settled in what proved to be a bleak situation, and it is feared that the disappointment he experienced helped to hasten his end.

TRADE NOTES.

Messrs. William Paul and Son, Waltham Cross, Lim., have received a renewal of their Warrant of Appointment (already held under their late Majesties Queen Victoria and King Edward VII.) as rose growers to his Majesty King George V., and also a Warrant of Appointment as rose growers and nurserymen to her Majesty Queen Alexandra.

The brochure issued by the Native Guano Company, of 29, New Bridge Street, Blackfriars, London, containing the reports from various parts of the country on the use of Native Guano is of much interest for the evidence it contains of the usefulness of the fertiliser in the cultivation of the various garden and farm crops. We have not counted the reports, which are throughout most favourable, but there must be a goodly number, for they occupy over sixty pages, and they are so short that they probably average eight to the page. We would add as a point of practical importance, that this is the thirty-fifth series of reports on Native Guano that have been issued by the company.

GARDENING ENGAGEMENTS.

Mr. F. H. Harris, formerly head gardener to Herbert Morrell, Esq., Streatley House, near Reading, has been appointed head gardener to the Right Hon. Viscount Galway, at Serlby Hall, Bawtry.

Prudential Assurance Company, Lim.—The directors state in their annual report for the year ending December 31, 1910, that in the ordinary branch the number of policies issued during the year was 80,311, assuring the sum of £7,462,496 and producing a new annual premium income of £446,473. The premiums received during the year were £4,806,121, being an increase of £96,014 over the year 1909. The claims of the year amounted to £3,240,957. The number of deaths was 8,465, and 19,157 endowment assurances matured. The number of policies in force at the end of the year was 903,896. In the industrial branch the premiums received during the year were £7,426,317, being an increase of £254,547. The claims of the year amounted to £2,805,069, including £222,506 bonus additions. The number of claims and surrenders, including 4,600 endowment assurances matured, was 371,023. The number of free policies granted during the year to those policyholders of five years' standing and upwards who desired to discontinue their payments, was 145,187, the number in force being 1,608,935. The number of free policies which became claims during the year was 42,660. The total number of policies in force in this branch at the end of the year was 18,820,427; their average duration exceeds eleven and three-quarter years. The assets of the company, in both branches, as shown in the balance-sheet, after deducting the amount written off securities, are £77,529,226, being an increase of £3,327,525 over those of 1909.

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

THE KELWAY "ARTISTIC" BORDER makes a garden of enduring beauty, from early spring to late autumn, with a minimum of cultivation, and without the trouble of constant digging or bedding-out. The plants composing the border are from strong country-grown stocks, which will flourish under almost all conditions. Send dimensions of space to be filled, or write for Kelway's "Gardens of Delight" (6d.). The cost of the "Artistic" Border is 15s., or 25s. for 10 square yards

KELWAY and SON, the Royal Horticulturists, LANGPORT, SOMERSET.

NOW IS THE TIME TO PLANT KELWAY DELPHINIUMS, which have been improved almost out of recognition in the past twenty years. They produce plants ranging in height from four to eight feet, exceptionally hardy, and with a rich profusion of choice blooms in all the shades of blue.
Choice named varieties: 24s. 34s., and 56s. a dozen.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

EVERY Gardener, amateur or professional, will find a large amount of useful information in the new edition of Kelway's "Manual of Horticulture"—the varieties, prices and culture of all sorts of garden plants, particularly those wonderful improvements raised in the Kelway Nurseries at Langport. A copy will be sent post free for 2s., which will be credited on the first order.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

KELWAY GLADIOLI flower freely in the open air through the autumn. Their fine bold blooms make an admirable addition to borders or beds and are invaluable as cut flowers for church or table decoration. Choice named collections, 3s., 4s. 6d., 6s., 7s. 6d., 9s., 12s., and 18s. a dozen.
Order at once.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

"CARRUSTICIDE."
The Best and Cheapest Remedy for Carnation Rust and other Fungoid Diseases.

A well-known Carnation Grower writes:

Dear Sir, The Nurseries, March, Cambs.

"During the 27 years I have been growing Carnations (Perpetual and American) I have tried most of the fungicides placed on the market, but yours is the best. It is a pleasure to see how "Carrusticide" catches hold of the Rust and destroys it. I should say your preparation will be extensively used when it is better known." Yours very truly,

GEO. CLARKE.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

◆

The Scottish Horticultural Association.

Taking a keen interest in the various associations that have for their object the advancement of horticulture and the improvement of the position of gardeners, we have felt that the presidential address which Mr. W. H. Massie delivered at the February meeting of the Scottish Horticultural Association is deserving of the fullest consideration. It is especially deserving of attention for the evidence it affords of the difficulty experienced in achieving complete success, even by men of high ability, when the essentials thereof fail to receive the fullest consideration, and the details of the project, whatever it may be, are not thought out from the business point of view. The address is of interest also from the fact that Mr. W. H. Massie has, in his review of the past and future of the association over which he so ably presides, dealt with the problems requiring solution from the business standpoint, and has had the courage of his opinions in suggesting reforms he considers necessary to enable the association to carry out the more important of the objects for which it was founded. It will be admitted, and by no one more readily than by ourselves, that the Scottish Horticultural Association has done an immense amount of good work during the twenty-four years that have elapsed since its foundation. But it made the initial mistake of adopting too low a rate of subscription, a fact which Mr. Massie recognises, and refers to in the concluding part of his address which we publish in this issue. It was, of course, necessary that the rate of subscription should be such as would enable the Scottish gardeners generally to become members; but it ought to have been recognised that it would be quite impossible to do much beyond holding monthly meetings with an annual subscription of half-a-crown. It was no doubt thought that a low subscription rate would ensure a large membership, and it may also have been thought that "mony a mickle mak a muckle." If this was the case, the anticipation has been fully realised, and the old Scotch proverb has come true enough, but in a way different from the one expected. Each member necessarily causes certain expenditure, and if his subscription is not in excess thereof there is no advantage, from a strictly financial point of view, in having large numbers of members. Bearing the fact in mind that the subscriptions of 1,000 members at half-a-crown each only amount to an annual income of £125, it is somewhat surprising that so able a horticulturist as the late Mr. Malcolm Dunn should have spoken in so highly an optimistic manner in the presidential address which he delivered three years after the foundation of the association with regard to the proposed library. During the following ten years other presidents spoke in a similar strain, and successive Councils referred to the desirability of forming a library as soon as the funds would permit, but no suggestion appears to have been made with regard to providing the necessary funds until Mr. Massie recommended the other day the raising of the rate of subscription. We are not certain that Mr. Massie goes quite far enough in his proposal, because a long time must elapse before there will be an appreciable increase in the income if new members only are to pay at a higher rate. We believe that the majority of the members would readily increase their subscriptions if they had evidence of an endeavour being made by the Council to form a comprehensive horticultural library. It was unfortunate that a portion of the profits derived from the earlier chrysanthemum shows was not annually invested for the purpose of purchasing gardening books as opportunities offered, as, if this had been done, a substantial sum would have soon been obtained. So far from this being done, the great success of these exhibitions resulted in the question of a library being lost sight of. We were pleased to find that Mr. Massie effectively disposed of the question of establishing a museum, because its cost would be quite out of proportion to the use that would be made of it, and also of the question of establishing educational classes, which are plentiful in Edinburgh. But his suggestion for the encouragement of the younger members to fully equip themselves for the responsibilities that in due course they will have to bear, is worthy of sympathetic consideration. Should the association undertake the important work of granting certificates for proficiency in horticulture, we trust they will formulate a scheme by which those of a higher grade can only be granted to men who have had several years of practical work in the garden or nursery, and preferably in both. In the training of gardeners there must be practice with science, for only by that means is it possible to obtain a full knowledge of practical details and the scientific principles that underlie them. Space will not admit of our properly discussing the question of the amalgamation of the Royal Caledonian Horticultural Society and the Scottish Horticultural Association, which has so greatly exercised the minds of the members of the Councils of these two great bodies, nor does it appear likely that at the present juncture any useful purpose would be served in doing so. If it be impossible for the two societies to form themselves into one body with advantage to Scottish horticulture, some endeavour should be made to formulate a scheme by which competition between the two societies will, as far as possible, be avoided. The two societies that have their headquarters

MR. THOMAS COOMBER, V.M.H.

in Edinburgh are by no means weak in capacity for good work or in finances, but we should like to see them welded into one strong body, possessing a botanical and horticultural library, and holding exhibitions at such periods of the year as may appear desirable, and monthly meetings at which Scottish horticulturists would have opportunities for becoming acquainted with new and little known plants, fruits, and flowers, and, it may be, hear lectures from the leading authorities.

Mr. Thomas Coomber, V.M.H.—It is with very great pleasure we publish this week a recent portrait of a very old friend and contributor to the pages of the Gardeners' Magazine—Mr. Thomas Coomber, head gardener to Lord Llangattock, The Hendre, Monmouth, and one of the most recent recipients of the Victoria Medal of Honour in Horticulture. Though a Southerner by birth, Mr. Coomber began his gardening career in Aberdeenshire, at Crimmonmogate, subsequently serving for various periods at Knole Park, Sevenoaks; Woburn Abbey, Bedford; Pencarrow, Cornwall; Messrs. James Veitch and Sons' Chelsea Nurseries, and Rendlesham Hall, Suffolk. For thirty-six years Mr. Coomber has been at The Hendre, and he has brought the now famous gardens into a very high state of cultivation. Fruit culture is Mr. Coomber's great forte, though he would be famous in other directions were it not for the fact that he rarely exhibits any other produce than fruit. An orchard entirely enclosed with bird-proof wire netting is one of the features of The Hendre, while peach, pear, and apple culture reach an unusually high position, notwithstanding adverse soil and position. But, though all indoor and outdoor fruits are splendidly managed, Mr. Coomber is perhaps best known for his skill as a cultivator of pineapples, wonderful specimens of which he exhibits once or twice a year in London. Few who saw the display of strawberries from The Hendre at the Holland House Show two years ago will readily forget the splendid fruits staged. The relations between gardener and employer are particularly pleasant at The Hendre, and we well remember a few years ago when Lord Llangattock presided at the festival dinner of the Gardeners' Royal Benevolent Institution, how feelingly he referred to "my friend Coomber." We hope it will be a very long time ere, from any cause, these relations are broken.

The King and the Gardeners' Royal Benevolent Institution.—We are delighted to learn that the King has forwarded his annual subscription of £5 to the above charity, of which his Majesty is patron.

Spring Work Among Hardy Flowers.—In view of the importance of the work now requiring attention at this season of the year in the several departments of the garden set apart to hardy plants, we shall devote our next issue (March 25) chiefly to rock and water gardening, and the hardy plant borders. The principal contents will include articles written by well-known experts on "Seasonal Herbaceous Borders," "Spring Planting in the Rock Garden," "Dwarf Conifers for the Rock Garden," "Autumn Flowers for Rockeries," "The Selection and Planting of Water Lilies," "Waterside Flowers," "Perennial Asters," "Herbaceous Phloxes," "Violas," and "Gladioli and Montbretias." The issue will be profusely illustrated and the numerous illustrations will have special reference to the various subjects dealt with.

Lieut.-Colonel Prain, F.R.S., director of the Royal Botanic Gardens, Kew, has been elected a member of the Athenæum Club under the provisions of the rule which empowers the annual election by the committee of a certain number of persons "of distinguished eminence in science, literature, the arts, or for public services."

The Rose Annual for 1911 has been issued, and as the volume evinces a considerable improvement upon the most successful of its predecessors, the members of the National Rose Society have good cause for being fully satisfied with the budget of information on roses and rose culture with which they have been provided. The "Annual" opens with an article in which the Rev. J. H. Pemberton, president of the society, passes under review the rose season of 1910; and with reference to the development of roses, he states that he cannot remember "a worse exhibition season," and that "never was there such a dearth of specimen blooms." In the following article Mr. H. R. Darlington deals with the characteristics and merits of twenty-five climbing roses selected by the Publications Committee, and, as in the preparation of his notes Mr. Darlington has had the assistance of some of the leading rosarians, the contribution will be found of quite exceptional value. Of a high degree of merit also is the interesting article on the decorative value of roses from the pen of Mr. R. Forester Felton, who is especially well qualified to deal with such a subject. Mr. George Paul, V.M.H., gives his impressions of the roses shown at the Paris International Exhibition in 1910. The series of short articles on the preparation of rose beds on various soils, by Mr. E. J. Holland, Dr. A. H. Williams, Rev. F. Page-Roberts, Mr. V. Rolt, Mr. C. C. Williamson, Rev. J. B. Shackle, Mr. J. T. Strange, Mr. F. Dennison, and other rosarians, contain much useful information on this important detail of rose cultivation. Dr. A. H. Williams deals with the important question of the date of the flowering of roses, and suggests that more attention should be given to this point. There is an interesting communication on the cultivation of roses in Australia, and one certainly not less interesting on their culture in Rhodesia. Mr. E. Mawley, V.M.H., contributes as usual his analysis of roses shown in the previous year. The "Annual" is freely illustrated, but the illustrations are somewhat unequal.

Royal Horticultural Society's Exhibition on Tuesday was remarkable for its extent and interest, and also for the immense number of Fellows and their friends who were present. Throughout the afternoon the whole of the available space was densely crowded, and between three and four o'clock it was extremely difficult to leave the hall. It might be an advantage were arrangements made for providing an exit at the south door, when, as on this occasion, the hall is excessively crowded, for the purpose of relieving the congestion in the entrance hall. There can be no question as to the fine displays provided by the Royal Horticultural Society being fully appreciated by the Fellows.

Gift of a Public Park to Lockerbie. The inhabitants of Lockerbie, N.B., have just received a handsome gift in the shape of a public park, convenient for the town, and in every way suitable for the purpose. It consists of a field of about five acres, which has been generously presented to the burgh by Sir Robert W. Buchanan Jardine, Bart., of Castlemilk, Dumfries-shire. The park is for the purposes of recreation, etc., and is a strong evidence of the interest taken by the donor in the district. The intention of Sir R. Buchanan Jardine is that the park should be called the King Edward Park, and form a memorial of his late Majesty.

R.H.S. Narcissus Committee.—At the first meeting of this body for the present year a very hearty vote of thanks was tendered to Mr. H. B. May, now moved on to the Floral Committee, for his services as chairman during many years, and an equally hearty welcome was accorded to Mr. A. E. Bowles, the newly-appointed chairman. A vote of sympathy to the members of the family of the late Mr. Jas. Walker, was passed; Mr. Walker was one of the original members, and one very highly respected. It was reported that the Duke of Bedford had contributed £100 to the Barr Memorial Fund, the latter now rapidly approaching £300.

Marie Louise Violets from Gainsborough.—From Mr. J. H. Creed, gardener to J. H. Sandars, Esq., North Sandsfield, Gainsborough, we have received a box of exceptionally fine Marie Louise violets, every flower of greater circumference than a half-crown piece. In size, fragrance, substance, and length of stem these charming flowers give evidence of exceptional cultural skill. Mr. Creed wrote, a week ago, "We have had a splendid lot of these violets all through the winter, and now the plants are a mass of blue blossoms."

Southern Counties (Scotland) Gardeners' Mutual Improvement Association. In order to promote the movement in favour of the establishment of a Mutual Improvement Association for the gardeners of the southern counties of Scotland, a meeting was held in the King's Arms Hotel, Dumfries, on March 5, when Mr. Hunter, of Messrs. James Service and Sons, Dumfries, had kindly consented to give a paper on the advantages of such associations. Mr. Hunter's paper was an excellent one, pointing out the many benefits which resulted to those connected with such educational bodies, and giving much useful information and suggestive material on the subject. Mr. Hunter was heartily thanked for his paper. A committee has been appointed to select a suitable meeting-place for the association.

The "Kew Bulletin" for the current month, among other interesting matters, contains communications relating to the beechwood industry of the Chilterns, rubber cultivation in Togoland and German East Africa, Mallet bark, the disease of the lilac caused by the fungus known as Helminthosporium syringæ, the Japanese species of Cerastium, and the park system of the Niagara Falls.

New Sweet Pea and Rose Society at Bury St. Edmunds.—At a meeting held in the Guildhall, Bury St. Edmunds, a few days ago, presided over by the Mayor, the Bury St. Edmunds and West Suffolk Sweet Pea and Rose Society was formed. This new society will not run counter to the Bury St. Edmunds Horticultural Society, as the latter body has decided not to hold a summer show. The Marchioness of Bristol has been invited to become the first president, Mr. Walter Norton will act as secretary, and Mr. W. J. Arnold as treasurer. It is probable that the exhibition in July next will be held in the Town Hall, but if the new society desires to hold its show in private grounds, Mr. C. J. E. Sparke has kindly placed his grounds at the disposal of the committee.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

The ordinary meeting of the R.H.S. was turned into a great two-day exhibition on March 14 and 15, and besides the many and beautiful exhibits coming before the standing committees, there were competitive classes, for prizes offered by the Royal Dutch Bulb Growers' Society. The great hall in Vincent Square was filled to overflowing, and we believe some few exhibits got stowed away upstairs, and were seen by very few folks. Daffodils, alpine flowers, tulips, forced flowering shrubs, and orchids were the great feature of a show that on the first day was so crowded with Fellows and visitors that almost everyone was complaining of the heat and jostle, while, a little later, the nurserymen and their assistants were tired out.

FLORAL COMMITTEE.

A superb exhibit, the most striking in the show, was one entirely of alpine plants, staged splendidly by Mr. J. Grandfield, gardener to Sir Everard Hambro, K.C.V.O., Hayes Place, Kent. It is quite impossible for us to convey to readers the full beauty of this magnificent exhibit. Rhododendrons, kalmias, and a few daffodils, formed a background for superb batches of Primula denticulata, P. malacoides, P. denticulata alba, P. cashmeriana, Saxifraga apiculata, S. Boydi alba, S. Burseriana, S. Petrachi (A.M.), etc., and smaller groups and plants of hardy cyclamen, Primula frondosa, P. Mrs. J. H. Wilson, Rhodothamnus chamæcistus, Muscari Heavenly Blue, Androsace Chumbyi, Iris reticulata, Erica carnea, etc.

Mr. A. A. Fabius, Redlands Nursery, Emsworth, showed again the graceful Adiantum Gloire of Moordrecht.

The alpine garden set up by Mr. H. Hemsley, Brighton Road, Crawley, contained Rhododendron racemosum, Saxifraga sancta, Cytisus Ardoinei, Iris reticulata, Lenten roses, anemones, and primulas.

Finely-grown violets, the varieties being the single Kaiser Wilhelm and La France, came from Mr. Harris, gardener to the Earl of Clarendon, Watford—the flowers were of grand size.

Messrs. R. H. Bath, Ltd., Wisbech, presented a very interesting exhibit, consisting of a large collection of tulips, hyacinths, daffodils, and crocuses, grown in fancy bowls in moss fibre. It was a group that the amateur visitors lingered long over.

Forced flowering shrubs in great variety, from Mr. L. R. Russell, Richmond, were greatly admired for the fine Azalea mollis, lilacs, and the graceful Jasminum primulinum. Mr. Watts, St. Asaph, North Wales, showed a few pans of glorious blue polyanthus primroses, full of flower, and blooms of grand size, colour, and substance.

Messrs. H. Cannell and Sons, Swanley, had a goodly exhibit of cut zonal pelargoniums showing brilliant flowers of the new bedding variety Salmon Paul Crampell, Scarlet King, Lady Roscoe, Lady Warwick, Burford, Amphitrite, and Hibernian.

Coloured primroses, largely of blue shades, and fine as regards size and freedom, were displayed in large round baskets by Messrs. Blackmore and Langdon, Twerton Hill, Bath.

The glorious carnations from Mr. H. Burnett, Guernsey, were a fine feature of the meeting, the blooms being large and of grand colour; very lovely were R. F. Felton, Mikado, Enchantress, Alma Ward, Fortuna, Marmion, Mrs. C. F. Raphael, White Enchantress, Emperor, Mrs. Tatton, Bridesmaid, and Afterglow, and all were shown in large vases.

Messrs. Wm. Paul and Son, Waltham Cross, filled one corner of the hall with camellias, the lovely Prunus triloba, crimson-flowered peaches, and double almonds—a delightful exhibit of forced shrubs.

Pans of hepaticas, double and single, squills, muscaris, anemones, crocuses, hardy heaths, primulas in variety, and saxifragas were presented by Mr. J. Reuthe, Keston, and backed by rhododendons and other shrubs.

Messrs. R. Gill and Sons, Tremough, Penryn, Cornwall, again showed their fine new Primula Winteri, and a lovely lot of trusses of arboreum rhododendrons, these being very fine.

A large display of primulas from Messrs. Sutton and Sons, Reading, just inside the main entrance, attracted a great deal of attention. The group was composed of well-grown and finely selected strains of Primula obconica, showing a fine range of colours, from white to deep rosy-crimson; three little groups of P. Kewensis lent additional brightness to the exhibit.

SAXIFRAGA PETRACHI.

Flowers pure white. A.M., R.H.S., March 14. Sir Everard Hambro, K.C.V.O., Hayes.

Messrs. W. Cutbush and Son, Highgate, contributed a group of forced flowering shrubs, in which lilacs, magnolias, and rhododendrons figured prominently; this firm presented a fine group of hepaticas in various colours, double and single, and they also set up some handsome perpetual carnations, notably Mrs. Fortescue, Lady Coventry, Marmion, Lady Norah Brassey, and the bright Rose Doré.

A very brilliant contribution from Messrs. Jas. Veitch and Sons, Chelsea, embraced a fine lot of Indian azaleas, including the lovely A. amœna Hexe, some fine imantophyllums, the exquisite Camellia reticulata, Primula Kewensis, the fragrant Boronia megastigma, and a number of glorious amaryllis, the varieties being Leda, Ena, Favonius, and Baletus; Cineraria Feltham Beauty, a blue cactus-flowered variety, was very elegant and beautiful.

The exhibit from Messrs. H. B. May and Sons, Edmonton, consisted of neat, freely-flowered Indian azaleas, a selection of the newer plumose nephrolepis, some gymnogrammas, and davallias.

Lenten lilies shown by Messrs. Barr and Sons, Covent Garden, were interesting, and so were the gerbera hybrids, and the lovely little crocuses, squills, hardy heaths, freesias, Primula malacoides, P. denticulata, anemones, and other charming early flowers.

Messrs. T. S. Ware, Feltham, set up a small rock garden exhibit in one of the annexes, and furnished it prettily with Soldanella alpina, Shortia grandiflora, Epigæa repens, Primula denticulata, and P. d. alba, hardy cyclamens, heaths, saxifragas, adonis, etc.

Hardy heaths, alpine shrubs, saxifragas, primroses, and Iris reticulata were the features of the exhibit from the Guildford Hardy Plant Company. The carnations from Messrs. Stuart Low and Co., Enfield, were very bright, and such varieties as Lady Alington, Scarlet Glow, Britannia, Black Chief, and Marchioness of Linlithgow were prominent.

Mr. Maurice Prichard, Christchurch, displayed Primula cashmeriana, and the white form, in splendid style, and presented a miniature rock garden furnished with dainty saxifragas, Primula nivalis, double primroses, Viola gracilis, and Anemone blanda in variety.

Messrs. R. Wallace and Co., Colchester, put up a quite bold rock garden filled with miniature shrubs, and groups of Anemone blanda, muscaris, Fritillaria meleagris, Primula Mrs. J. H. Wilson, Morisea hypogæa, Tulipa Kaufmanniana, Iris reticulata, etc., etc.

Mr. Clarence Elliott, Seven Hills, Stevenage, presented a very pretty rock garden, in which saxifragas were particularly good, notably the beautiful S. Burseriana.

Roses and lilacs, all deliciously fragrant, were shown in some quantity by Messrs. Paul and Son, Cheshunt; the small lilacs were finely flowered, and leading varieties were Alphonse Lavallee, Comtesse H. de Choiseul, alba grandiflora, Madame Abel Chatenay, and Madame Casimir Perier.

Messrs. Bakers, Wolverhampton, had beautiful little batches of Primula Cashmeriana, Trillium grandiflorum, Incarvillea grandiflora, Saxifraga sancta, Adonis amurensis.

Viola gracilis, Androsace sarmentosa, and hepaticas.

Lachenalia Nelsoni was superbly shown by Messrs. R. and G. Cuthbert, Southgate. They were in 48-sized pots, and crowded with spikes of soft yellow flowers.

Mr James Box, Lindfield, put up a big display, consisting of daffodils, tulips, hyacinths, and alpines, presenting these in the form of a decorative group.

Messrs. Heath and Son, Cheltenham, presented some delightful alpine plants, and notable things were Primula lilacina, a hybrid between Primula frondosa and P. rosea, alpine auriculas, heaths, and the beautiful Anemone nemorosa robusta.

Messrs. James Carter and Co., Holborn, covered themselves with glory by displaying a delightful spring garden right opposite the entrance. There was an admiring crowd round the display all the time, and it was difficult to discover whether the lovely green grass or the flowers were most admired. The background was of tall conifers, and below this was some rockwork filled with groups of daffodils, Iris reticulata, and breadths of crocuses, Rhododendron præcox, and snowdrops. There were two trickling fountains each bordered by yellow crocuses. In the centre was a bed of white hyacinths, with a raised ornamental vase of the pink tulip Royal Park. Along the front there were two semicircular beds of hyacinths, and two of tulips, the whole making up a delightful spring flower garden of charming design and great beauty, and all composed of simple subjects.

Mr. H. Ellison, West Bromwich, again brought forward a goodly collection of elegant ferns, and he also displayed among these several vases of beautiful blooms of hybrid gerberas.

The new deep pink rose, Mrs. George Shawyer, placed between several dozen lovely flowers of the yellow Lady Hillingdon, came from Messrs. G. Mount and Sons, Canterbury.

Mr. Prime, gardener to the Marquis of Salisbury, Hatfield, showed his skill with lachenalias by setting up a large batch of well-grown specimens, with a few crotons rising above them.

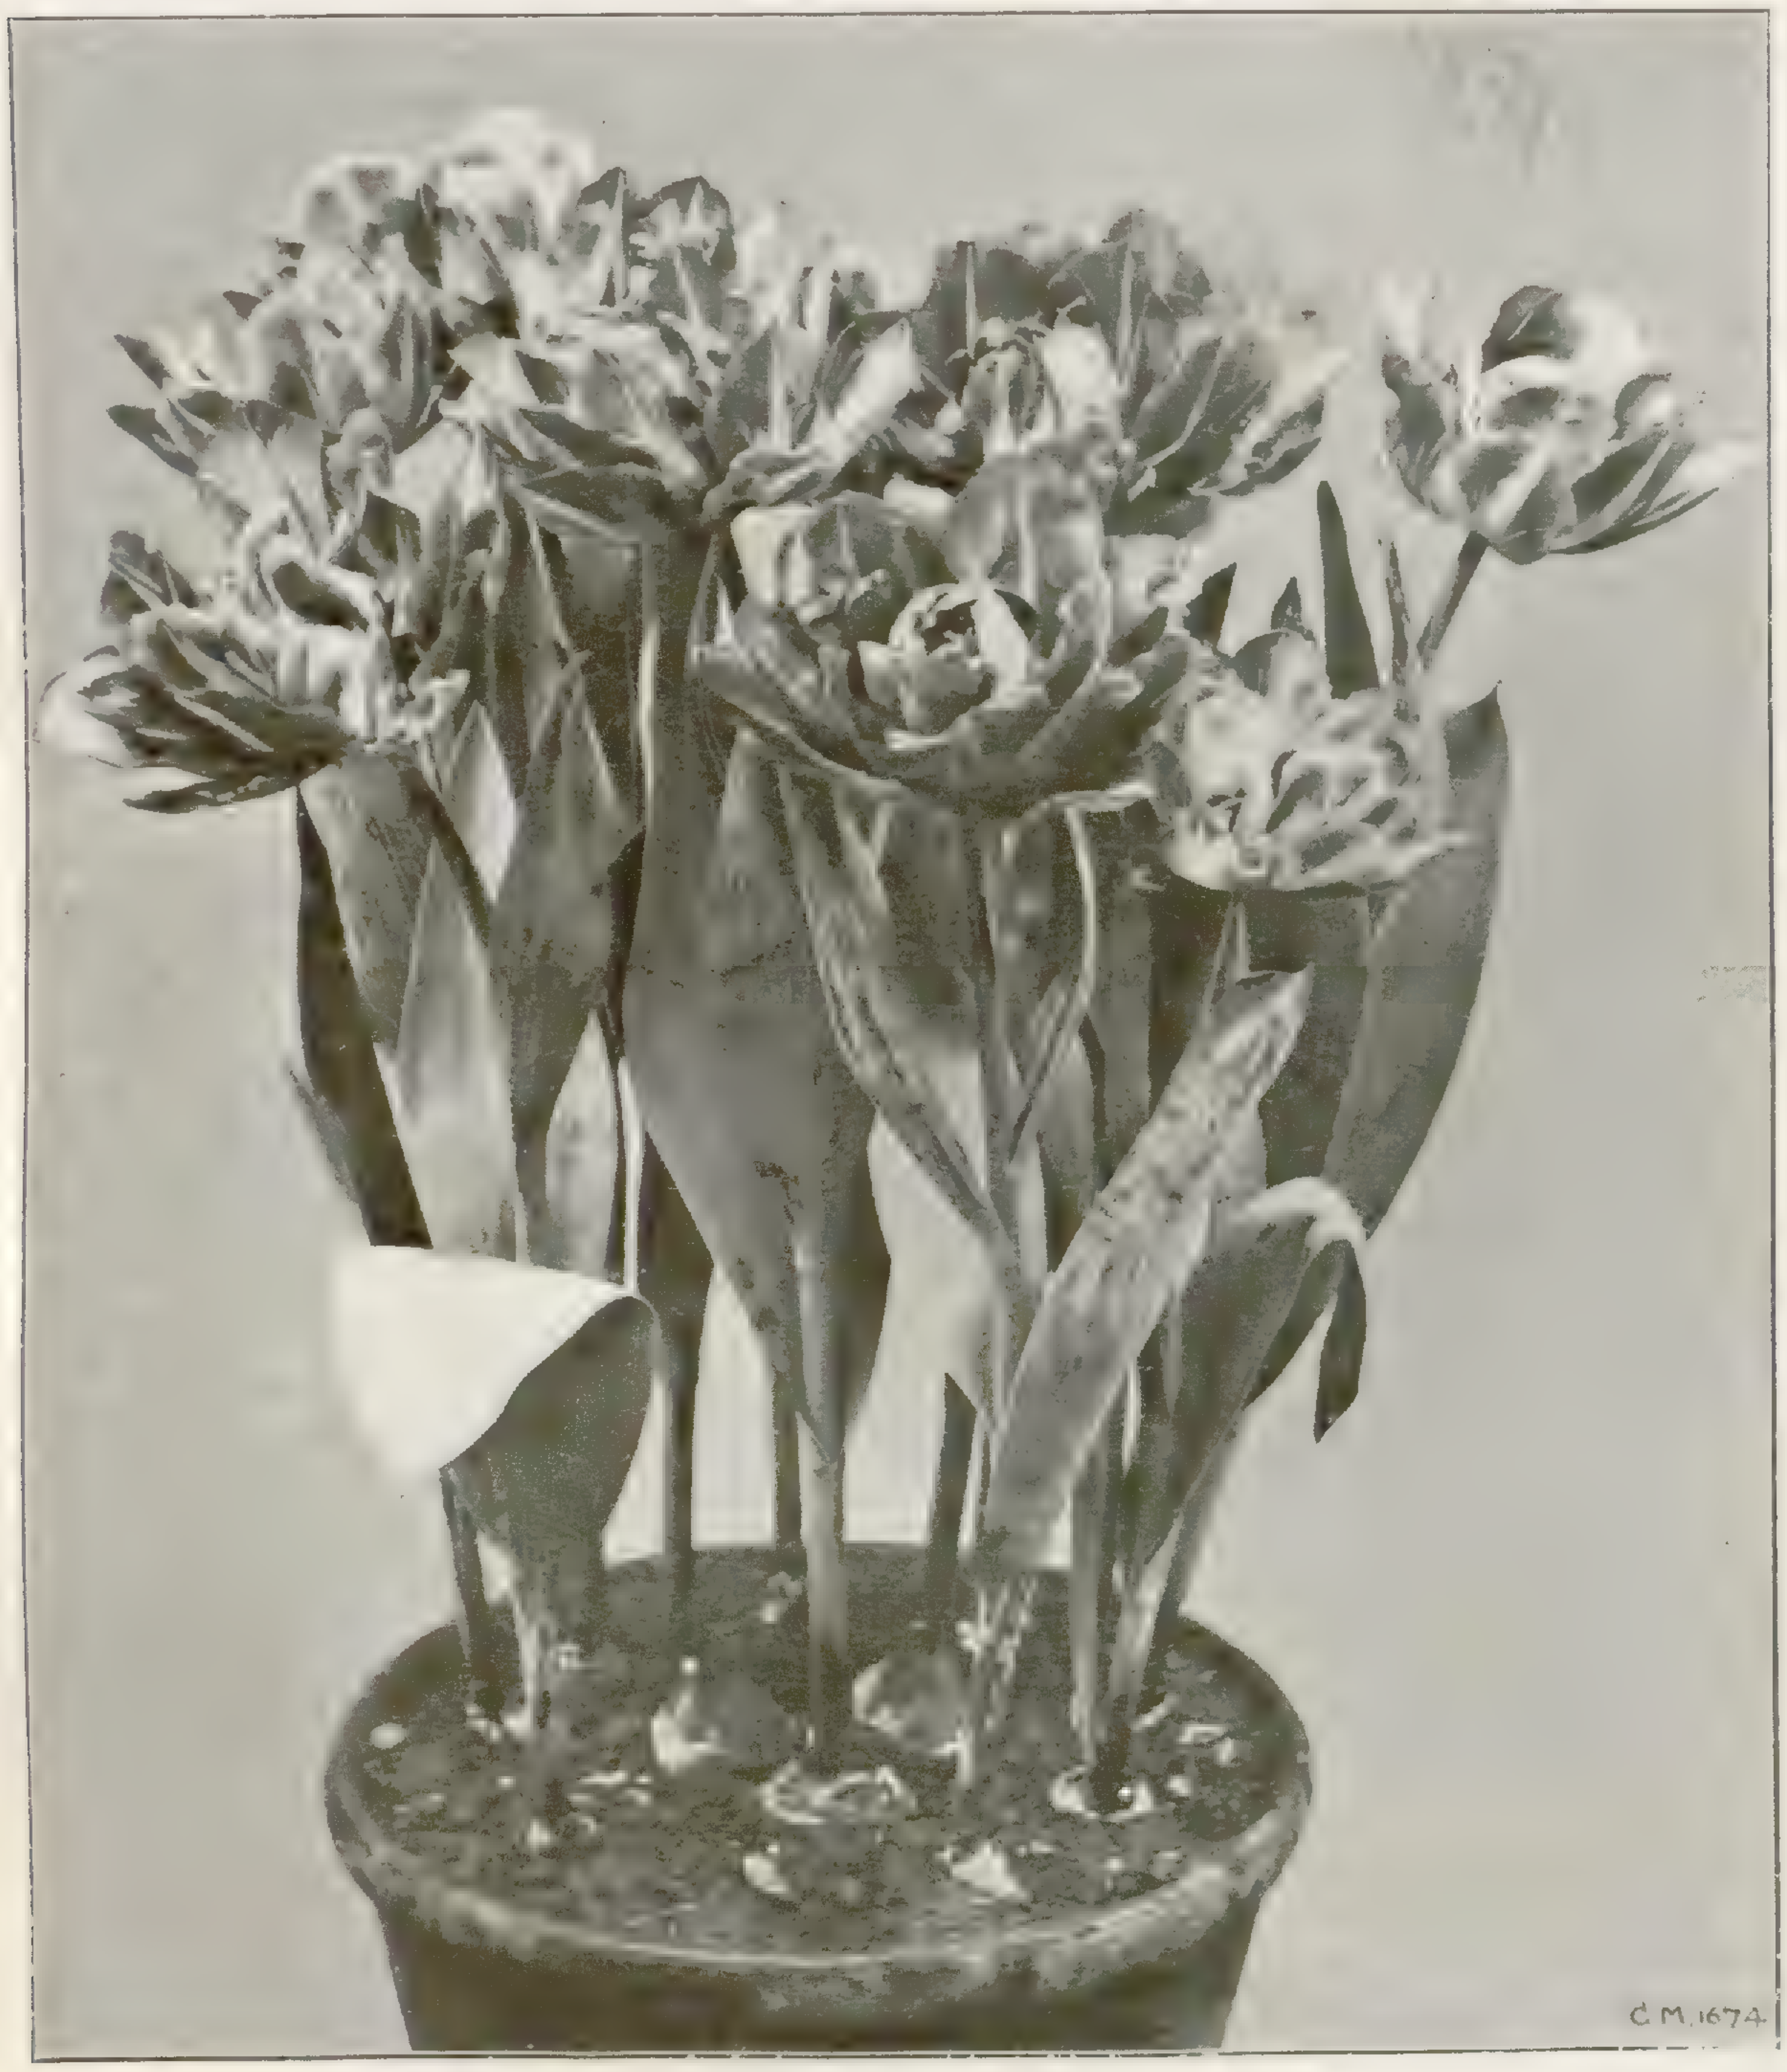
Mr. H. C. Pulham, Elsenham, was responsible for a small rock garden, neatly furnished with popular alpines.

Messrs. R. P. Ker and Son, Liverpool, showed a splendid white amaryllis, named Queen Mary, which gained an A.M.

Mr. C. Engelmann, Saffron Walden, exhibited a collection of perpetual carnations, the varieties most in evidence being Carola, J. Whitcombe Riley, and Mrs. H. Burnett.

Lachenalias were well shown by Messrs. J. Peed and Son, West Norwood, who also sent a small collection of alpines.

Messrs. G. Jackman and Son, Woking, brought up a pretty and interesting lot of saxifragas, anemones, primulas, and other alpines.



EARLY-FLOWERING TULIP YELLOW MURILLO.

Flowers double, and of a rich yellow hue. A.M., R.H.S., March 14.
Mr. Profittlich, Twickenham.

ORCHID COMMITTEE.

A goodly group of orchids from Messrs. J. Cypher and Sons, Cheltenham, included Lælio-cattleya Lady Miller, Cymbidium insigre Sanderæ, some good odontoglossums, Stanhopea eburnea, Leptotes bicolor, the grand Miltonia Bleuana nobilior, Brasso-cattleya Digbyana, Cattleya Mendeli, the fragrant Dendrobium aureum, and other good things.

Messrs. Sander and Sons, St. Albans, presented Cymbidium Gottianum (eburneum and insigne Sanderi), a spike of Schomburgkia undulata, Odontioda Bradshawæ, Phaius Norman, the finely margined Odontoglossum Braggense, Chysis Chelsoni, Renanthera Imschootiana, Odontoglossum Thompsoni, etc., etc.

An extremely beautiful display of orchids from Messrs. Charlesworth and Co., Haywards Heath, was also of considerable extent. The varieties of Odontoglossum crispum were of outstanding merit, though all light coloured. The hybrids included O. Rolfeæ, O. Wilckeanum, O. amabile, O. Sylvia, O. Warnhamense, O. Ossulstoni, Odontioda Bradshawiæ, O. Lutetia, O. Cooksonæ, O. heatonense, and O. Charlesworthi. Other fine things were Phaius Norman, very finely shown and grown; Lælio-cattleya Myra, Zygo-colax, Charlesworthi, Brasso-cattleya Maronæ, Cattleya citrina, and the handsome Brasso-lælia Veitchi var. King Edward VII.

Messrs. J. and A. McBean, Cooksbridge, showed a big Cymbidium Lowio-eburneum, Odontoglossum crispum, Cattleya Trianæ, and C. Schroderæ.

Dendrobiums were splendidly shown by Mr. Collier, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate, who had delightful plants of D. Lady Colman, D. nobile Harefield Hall var., D. rubens, D. signatum aureum, D. Wiganianum, D. Princess Patricia of Connaught, D. melanodiscus, and several charming unnamed hybrids.

Dendrobium Wardianum was the central feature of a group of orchids from Messrs. Stuart Low and Co., Enfield; round this were grouped Cattleya Schroderæ, C. Suzanne Hye, Renanthera Imschootiana, and Miltonia Bleuana nobilior.

Messrs. Armstrong and Brown, Tunbridge Wells, were represented by a large example of Odontoglossum nævium, O. Rolfeæ, O. crispum, O. amabile, Cypripedium Maudiæ, and Brasso-cattleya Lehmanniæ, with numerous and beautiful dendrobiums and masdevallias.

DAFFODIL AND TULIP COMMITTEE.

A remarkably fine exhibit from Messrs. R. and G. Cuthbert, staged along the top end of the hall, was a striking feature of the exhibition. It consisted entirely of tulips in pots, grouped in their varieties so as to make up a large and harmonious display. About forty varieties were on view represented by about nine hundred potsful. The flowers were delightful, and were a foretaste of spring. Leading varieties were Mon Tresor, Nellie, Pink Beauty, Pottebakker White, Prince of Austria, Vesuvius, Coleur Cardinal, Mr. Stanley, Maes, Joost van Vondel, Grace Darling, White Swan, Sir Thos. Lipton, Kaizers Kroon, Proserpine, and Van der Meer.

Messrs. Robert Sydenham Limited, Birmingham, submitted a group of interesting daffodils. The flowers clear and bright; Incognita, Great Warley, Homespun, Lady Margaret Boscawen, Firebrand, Dairymaid, etc.

Messrs. Cartwright and Goodwin presented a goodly collection of daffodils, and set these up well, with Isolepis gracilis between the vases. Very beautiful were the blooms of Leiden Jar, Mrs. H. J. Veitch, Trojan Boy, King Alfred, Ambrosine, Beacon, Castile, Barcarolle, Lulworth, Circlet, Robt. Browning, Mdme. de Graaf, and Libra.

Messrs. J. R. Pearson and Sons, Lowdham, Notts, put up a collection of daffodils, in which the outstanding varieties were Empire White incomparabilis, Blackwell, Heroine, Viga, Florence Pearson, Maximus, Seagull, White Queen, King Alfred, and Duke of Bedford.

Mr. Christopher Bourne, Simpson, Bletchley, put up his first exhibit of daffodils at the hall since joining the ranks of the trade. His effort was a capital one, and he had Whitewell, Tritoma, White Queen, Lullaby,

(Continued on page [illegible]3.)

THE COOL OR LATE PEACH HOUSE.

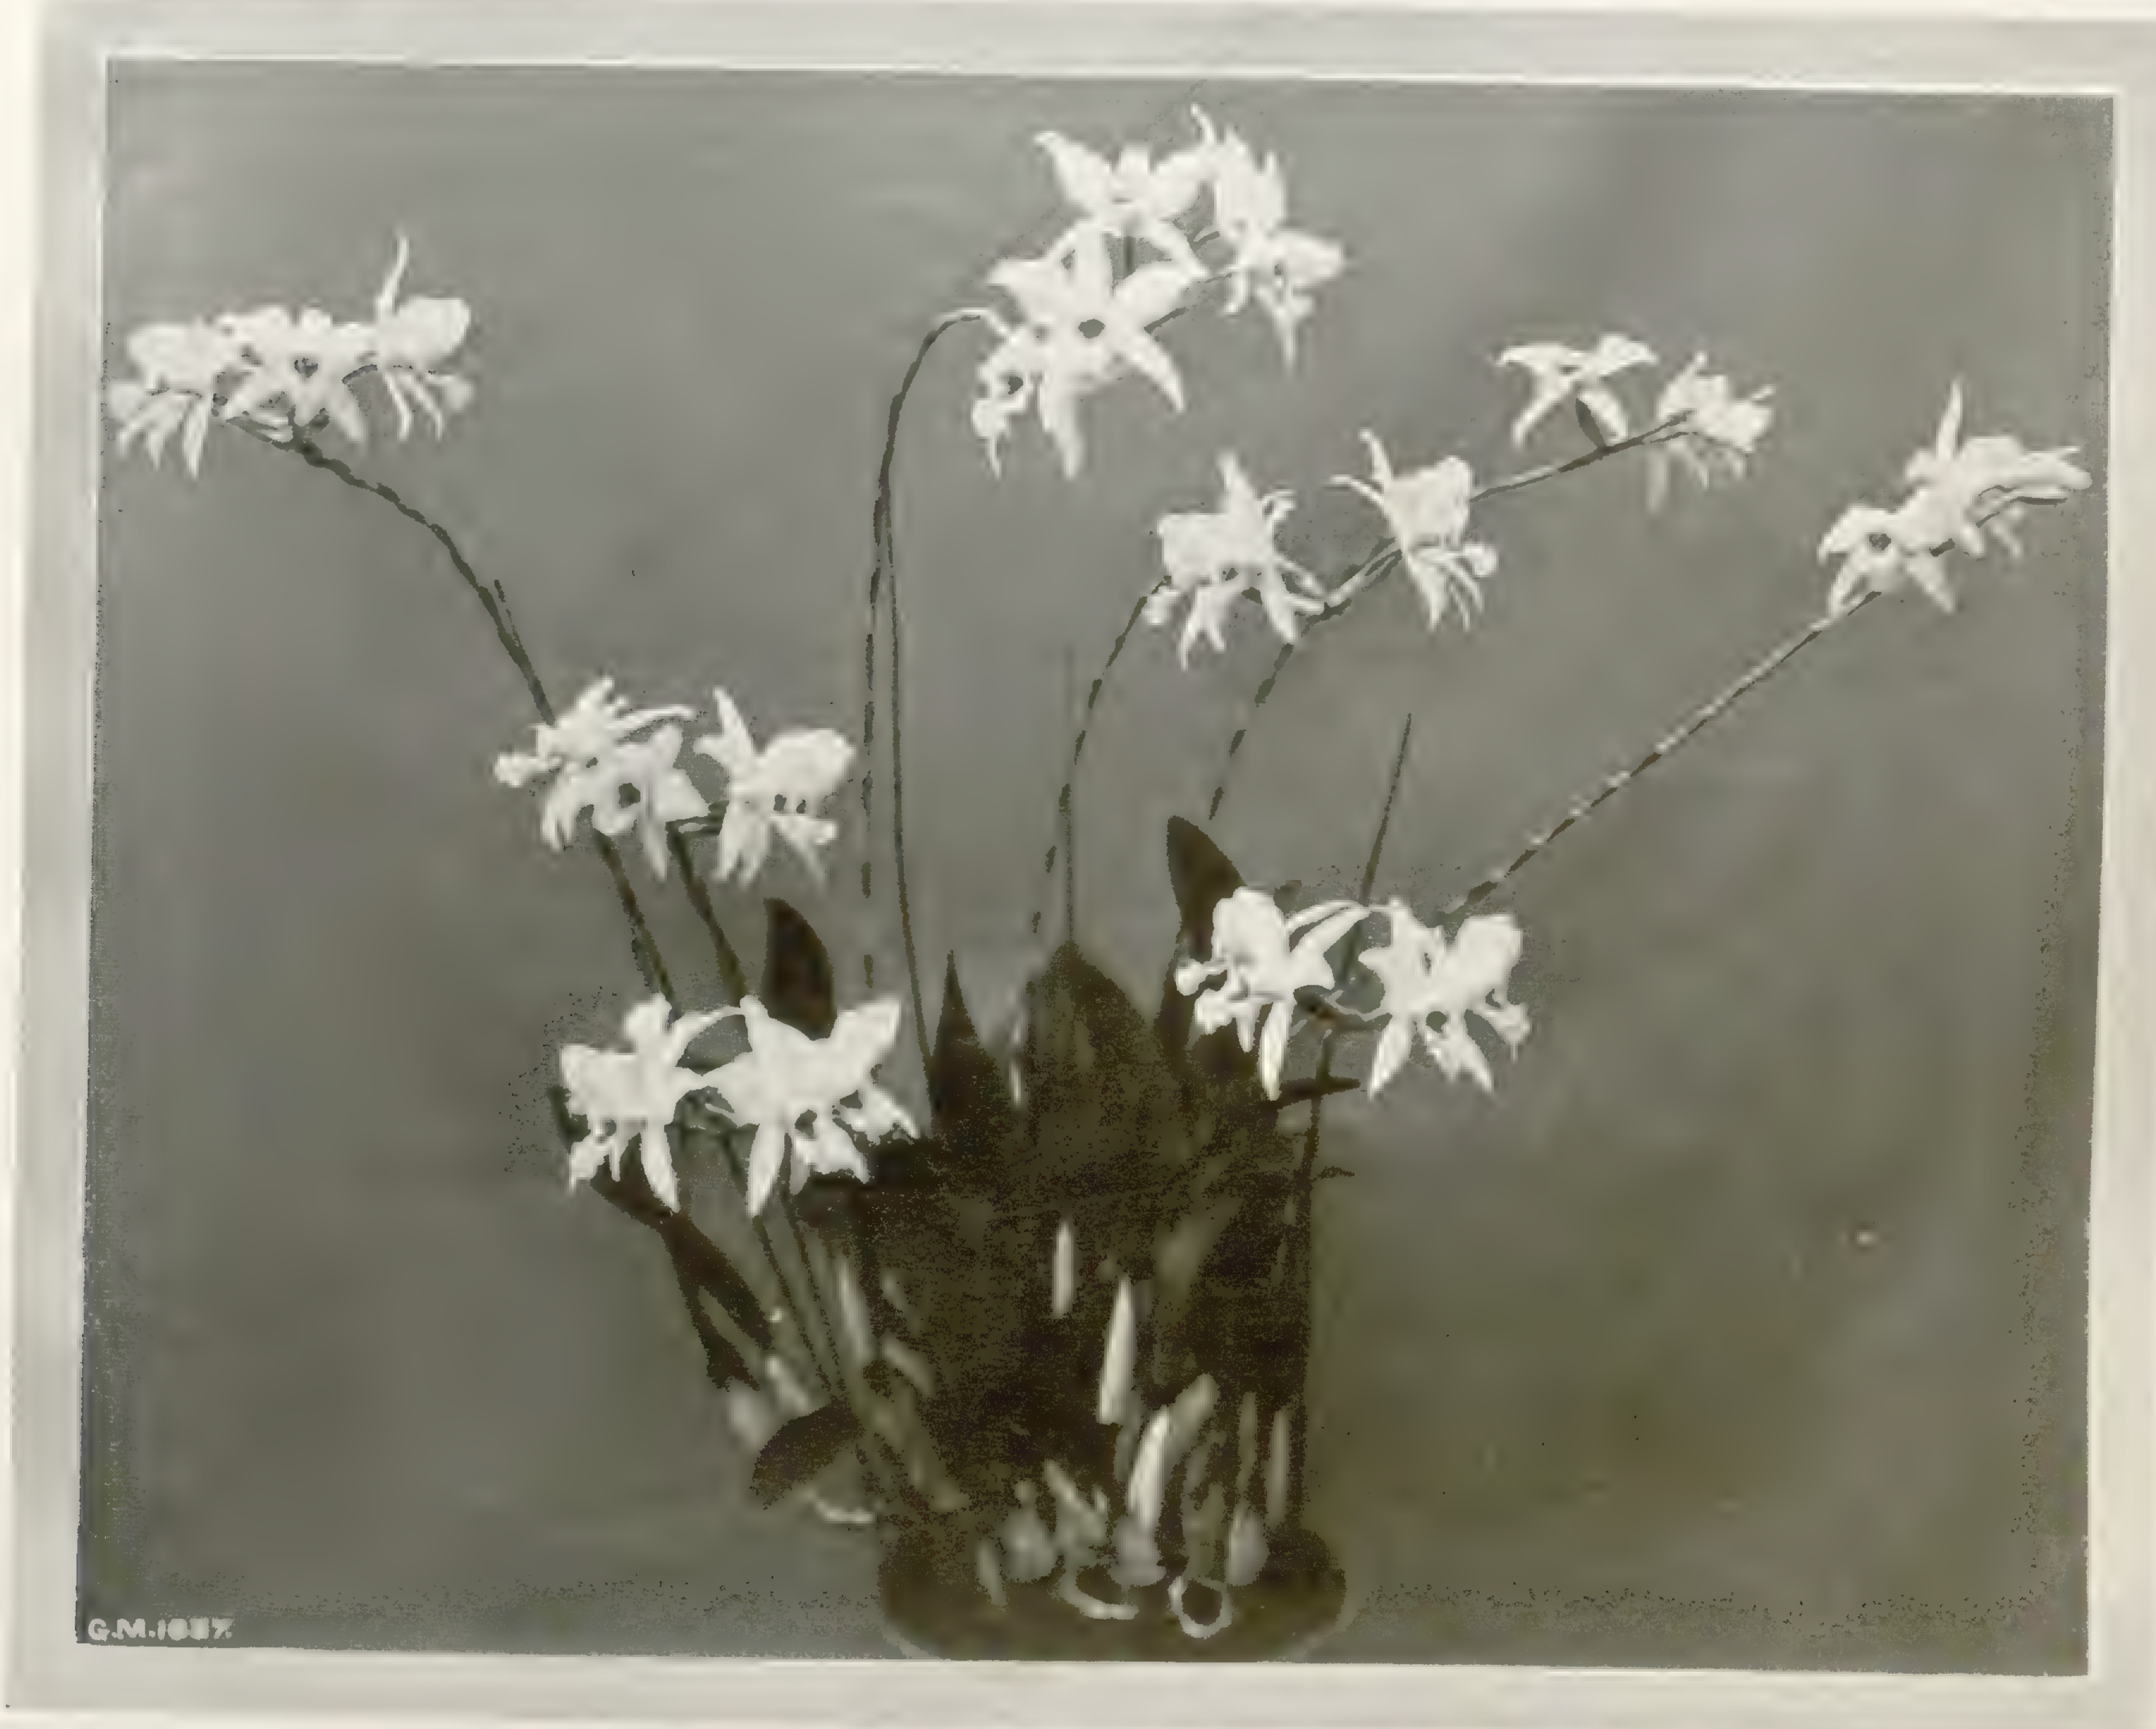
The cool peach house serves very useful purposes in many gardens, especially in those where outdoor peaches and nectarines are not grown, while, as a rule, owing to the comparatively simple and economical way it can be managed, it is the best description of peach house for the amateur, whether he grows his trees as bushes or pyramids, in pots, or as planted out trained specimens.

The houses may be either lean-to, facing south or nearly so, or span-roofed running north and south. In either case fruit of excellent quality can be grown, though, of course, that produced in the former, provided the varieties are the same, will ripen earlier than will those in the latter. I have seen heavy crops of good fruit produced in a somewhat flat-roofed lean-to house facing south-west. The trees were standards, planted along the centre of the house, with their branches trained star fashion upon an overhead trellis. This is by no means referred to as being an ideal case, but rather in order to point out that good results can be obtained by ordinary means, so far as houses are concerned. The necessity, or otherwise, of heating the houses depends upon their position, as though it is necessary in our low situation, as was once proved by a crop being ruined by frosts in March (previous to the house being heated) when the trees were in blossom, yet, it is not so in cases where the houses are situated at a high elevation, and in any case artificial warmth is only required while the trees are in blossom. It is very important, however, that peach houses occupying all positions should be adequately provided with both bottom and top ventilators.

The varieties used must depend in a great measure upon circumstances, for example, if fruit is only required to succeed that obtained from mid-season houses, then late, and the latest, varieties only should be planted, and in this case a house of moderate dimensions may suffice to meet demands. On the other hand, supposing, as in the case of some amateurs, it is the only peach house at command, it would be advisable to plant trees of both early, second early, late, and the latest varieties, with a view to command an unbroken supply of ripe fruit, covering as long a period as possible; and under these circumstances, in order to reap the most satisfactory results, a large house is indispensable. When adopting this course the earliest varieties should be planted at one end of the house, to be followed by the second early, and so forth. By this method the trees in each section of the house are simultaneously cleared of their fruit, and can thereby be the more conveniently and profitably attended to with respect to syringing and other details, and, if growing in borders, to watering also.

Apart from being a very interesting mode of management, there are advantages to be gained from growing the trees in pots, the chief of which is, perhaps, that a greater number of varieties can be grown in a given space than can be done by trained trees planted out; from them, moreover a succession of fruit can be kept up for a greater length of time than is possible from planted trees. Another gain to be reaped from pot culture is the fact that the trees can be cleared from the house during winter, and the house utilised for other purposes. Pot culture, however, it should be understood, enforces a relatively greater amount of labour in watering and manuring than does the planting-out system.

T. Coomber.



A FINELY-FLOWERED SPECIMEN OF LÆLIA ANCEPS SCHRODERIANA.
Recently exhibited at a R.H.S. Meeting by Lieut.-Colonel Sir George Holford.

A FINE WHITE LÆLIA ANCEPS

In our issue of March 11, and on p. 185, we gave an illustration of a fine specimen cattleya from Lieut.-Colonel Sir G. Holford's collection, and we now present our readers with another illustration of Mr. H. Alexander's skill. The Cattleya Trianæ Hydra referred to was the centrepiece in an exhibit of Lælia anceps at the Royal Horticultural Hall last February, and one of the finest of the Lælias, L. anceps Schröderiana, is here figured. It carried eight spikes of lovely flowers, the latter numbering three dozen. As an example of cultural skill, this must take high rank among the many fine specimens from the Westonbirt collection that we have figured in these pages.

CONCERNING FRUIT TREES.

American Blight, or Woolly Aphis, is difficult to get rid of in some places. If "E. M." has used all the remedies stated in his recent note, I strongly suspect that he has the root form of this pest at work, which is so constantly repeopling the tree with its kind as he destroys them. I am perfectly certain that the pest itself can be easily killed with much less drastic measures or crude materials than he suggests. Personally, I like attacking American blight in the summer time—July or August—when the young can be found running over the trees in search of fresh quarters, and also, a point I think most important, very frequently without the characteristic down upon them, which so often throws off the spray fluid.

I have used McDougall's Psylla Wash at a strength of one gallon to fifty gallons of water without doing any appreciable damage to the leaves of the tree, and so effectively as regards the aphis, that it was hardly possible to find one live one.

I have had the root form in another orchard, however, and find that there it is a very different matter to get rid of the pest, for the simple reason I have stated above, that the ground form is continually migrating to the upper part of the tree. One of the many chemicals which kill by means of the noxious gases given off must be used to combat this root louse. Either these in the form of powder or liquid can be used, the latter requiring a special apparatus with which to use them generally. Vermorel makes an apparatus by which any required quantity of the most dangerous liquids, like carbon bisulphide, can be safely and expeditiously injected amongst the roots of the tree. In consists of a reservoir fitted with a strong plunger at the top, and carrying also a pair of stout handles to assist in forcing the point of the tube, which forms the lower part, into the soil. For this purpose, and also to gauge the depth the chemical is being injected a pedal is fitted on to the point. One forces this point into the soil, taking care that no large roots are touched, until the pedal touches the top of the ground, then drives the liquid out by means of the plunger fitted at the top of the reservoir, which automatically measures the dose.

The use of the Northern Spy stock, which has been found both in America and Australia to be immune from the attacks of woolly aphis, does not seem to have taken on in this country. Only very isolated cases of its use in nurseries are to be heard of, though one is somewhat at a loss to understand why; perhaps we are all so concerned to get fruit quickly by the use of surface-rooting stocks as to care little or nothing for anything else.

Like "E. M.," I can hardly understand Mr. Petts' remarks concerning gooseberry trees, as I have known fine large trees which have gone to twenty and twenty-five years of age before being discarded. But I find still more serious fault with him concerning "pinching in May" and "pruning as soon as the fruit is gathered." His remark that gooseberries rarely make secondary growth is quite contrary to experience, I believe.

When the American gooseberry mildew order was first issued the inspectors insisted on the infected bushes in the green state being tipped—practically Mr. Petts' pinching—but soon afterwards such a course was abandoned, as it was found, particularly in the case of young vigorous trees, that the shortened growth almost invariably started again into two or three growths, which became infected with the mildew, and so doubled or trebled the area of attack. The Government inspectors evidently had considerable experience of this "shooting again," since they did not recommend "tipping" last year, but did their best to dissuade growers from carrying it out, at least that was my experience with those I came in contact with.

The question of canker in apple trees is a very wide and far-reaching one, in which it is more easy to make sweeping and dogmatic statements than to find a real reason for the disease. If we admit that neglect, want of pruning and spraying, unsuitable soils and imperfect drainage—each and all of them—help to cause and maintain canker, how is it that some varieties, like Newton Wonder, and Bramley's Seedling, do not appear to be at all affected, even under the most unsuitable conditions. As a matter of fact, all these factors, even including the question of varieties, have an influence on the liability or otherwise of apple trees to canker. Wounds caused by woolly aphis, by carelessness in clambering about the trees when picking the fruit, by the rubbing of two shoots upon each other, are all dangerous, since the spores of the particularly active fungus, Nectria ditissima, can find an entrance thereby.

Spraying, to be effective against canker, must be with a strong fungicide, and at a time when the conidia of the fungus are present, while a lot of force will be needed behind the spray, and careful judgment in directing it, to reach them in the wounds and beneath loose bark and rubbish. I believe some of the damage attributed to canker, that is to Nectria ditissima, is really the work of the Apple Scab fungus and the Brown Rot fungus, both of them chiefly known for their damage to the fruit, which is, alas! only one side of their destructiveness. By bursting open the bark of the young shoots in the spring the former causes ugly blotches, if not wounds, the bark often hanging in scales up the shoot, while the latter is, I think, often responsible for the dying fruit spurs seen on many apple trees. A really cold, unkind subsoil is most frequently blamed for canker, and many are the devices adopted to overcome it, ranging from the use of surface-rooting stocks to artificial methods like planting on top of a layer of brick rubble, or, in very wet soils, even on mounds raised above the ground level.

In this connection I have been very interested in the articles on deep cultivation which have appeared in these pages lately. Though agreeing in the main with it for vegetable culture, I fail to follow the arguments entirely, particularly with regard to fruit. If the idea of deep cultivation is the aeration of the subsoil so as to set free some of the valuable constituents of plant food locked up therein, I agree, but if it is a question of more efficiently getting rid of surface water I differ. With proper underdraining no difficulty of the kind should occur, and, unless there is such a system, deep cultivation only means removing the trouble a foot or two deeper without really remedying it. Then, with regard to fruit, are these deep-rooting trees going to produce fruit or wood? Personally, I fear the latter, unless in the trenching great care was taken to make the manurial contents of the subsoil suitable for fruit production. The wood probably would be healthy, and free from canker, for a time, but I should anticipate that the roots would pretty rapidly penetrate the loosened soil, and commence to take hold of the undisturbed element beneath, tending to set up the old conditions over again.

I am inclined to think that where it is known that the subsoil is unsuitable, for some reason or another, that the steps to be taken should be in the direction of keeping the roots out of it by judicious feeding, pretty much on the surface, to draw them up, and the avoidance of too deeply disturbing the soil, so as not to drive them down. I believe such a course to be possible in this country, where we are not subject to very severe droughts, especially if care is taken to conserve the moisture in the surface soil by maintaining a dust mulch with the hoe. I must admit I have no experience of apples in specially deep cultivated soils, and my premises are principally based on the experience with surface-rooting stocks, which seems to point to the opposite.

I know, however, some soils which are very deep, varying in staple from three to six feet, on which most luxuriant growth is produced, but it is very difficult indeed to induce the trees to fruit. I realise, of course, that exceptional fruitfulness is not everything, especially if it is accompanied by a tendency to unhealthy wood, but of the two evils, I know which, as a commercial grower, I would choose. I should like to see a proper series of experiments carried out with regard to this question of canker and the subsoil. Trees of most of the varieties of apples, particularly those disposed to canker, should be planted (1) in the ordinary way, (2) after deep cultivation, (3) on a medium of some sort which prevented the roots from going down (it would be necessary that the drainage water could get away easily, or trouble would occur). Sufficient of the trees should be planted to enable tests to be carried out in each case concerning the efficacy of spraying to ward off or cure the canker, and, perhaps, of manurial dressings for the same purposes. Only in some such way will the vexed question be solved, and fruit growers be saved much capital now annually lost through the decay and death of their trees.

F. Hammond.

Pear Monarch.—This is a grand pear for use during the months of December, January, and February, where the trees do well. In one garden I found it very disappointing, though other varieties succeeded with only ordinary care bestowed upon them. Monarch did not thrive, and cast its fruits badly, although the trees were carefully watched and given special treatment. The rooting medium was rather clayey, but it was well prepared, and while other varieties made good progress, Monarch grew very slowly, but the slow growth was partially due to the quince stocks. Judging from further experience I am inclined to think that the variety does best on the pear stock if root-pruning be judiciously carried out. Another variety, Fertility, did badly with me in the same circumstances, although in other gardens it was not difficult to grow fine bushes and crops of fruit; in the one I specially refer to the young trees could not be induced to make satisfactory growth; indeed, many branches died annually. This variety was also grafted on the quince stock. Flower buds formed freely enough, but the pears were very small. The roots were quite healthy.—G. B.

SWEET PEAS

Reach the greatest perfection when grown with Canary Guano. This Fertilizer increases the size and brilliance of the blossoms and doubles their number. The Fertilizer may be applied at time of sowing and as a top dressing during the early part of growth. Try it. Canary Guano is used all over the world and is sold by practically all Seedsmen

In Tins, **6d., 1/-, and 2/6,** and in bags from **3/6** to **20/-** each.

FOR GARDEN AND GREENHOUSE USE CANARY GUANO.

GARDENS OF ANNUALS.

"New every year," should be the motto of the maker of a garden of annuals, not only in the sense of providing fresh denizens of the beds and borders each season, but the occupants should also be of kinds not cultivated the previous summer. Originality has its claims upon us, but so, too, has change: a flower that has not been grown for a few years has increased in interest for us, and probably can be represented by a number of new varieties.

The best show of annuals can only be gained by early culture under glass; the kinds that will succeed from later outdoor sowings are, of course, numerous, yet the majority of these never attain the proportions, in plant or bloom, that is reached by similar sorts raised in frames or greenhouse, and kept in development from a much earlier time. Lobelia is a case in point [but it is not an annual, although it may be treated as one with the best possible results.- ED.]; the overcrowded plants, whether sown out or put out from late sowings made in boxes and not pricked off, give colour masses certainly, but to discover what the dwarf bedding lobelia can be it must have been raised in warmth, then transplanted seedling by seedling, not in bunches, an inch apart in larger boxes or frame beds.

Half-hardy annuals when finely cultivated will produce some of the most exquisite bedding displays. Salpiglossis has almost every merit, grace, rich and delicate colourings, beautiful veinings, and will continue in blossom from June until November if relieved of dead flowers as they fade on the stems. The plant needs sunshine, and ordinary, or light soil, responds to a mulch of old manure when producing its flower buds, and should be encouraged by liquid manure while blooming. To sow this late is to spoil it, the seeds should be put into glass-covered pans in a warm greenhouse early in March. Princess Ida, cream, veined with gold, is fit for mingling with Scarlet Salvia or Alonsoa Warscewiczi, or those other half-hardy annuals, Swan River daisies, the charm of the rose, white, or blue hybrids of which is not sufficiently recognised.

For dry gardens special use should be made of Grammanthes gentianoides, one of the gayest orange-vermilion carpet plants, with fleshy foliage; although quite a minute plant it should have the same care as is recommended for lobelia, then will form a dense mat of leaf and bloom as soon as established.

Perhaps the chief charm of an annual garden is its gradual change from the dullness of foliage to the brilliance of bloom; for a week or two after the bulbous plants, long past their beauty, have been removed, the beds and borders of transplanted annuals seem to make no show; then alternate showers and sunshine, and the plants kept from all root constriction and consequent premature budding, will burst into a perfect florescence. There is no comparison between the effect of a well-raised and an ill-grown datura, nicotiana, or cosmos.

Herbaceous plants, valuable though they must always be counted as occupants for large borders and some beds, of necessity fail in trim appearance, because their growth year after year is partly determined by soil and seasons, their height is influenced by their growth, and that height determines whether colour masses or lines shall be in close company with neighbouring colours or tower far above them. Annuals of any sort, grown for symmetry as well as hue, fulfil the purposes for which they were raised, and are then removed before they have time to deteriorate in habit. A sufficiency of bedding and cutting plants for a large garden can only be obtained from seed sowing where the gardener has plenty of greenhouse and frame space at his command, but orders given early to trade growers will be well carried out in May and June, so purchase of seedlings can assist the home efforts; even then the cost will be far less than is often incurred by the use of pelargoniums and marguerites, begonias, and calceolarias. Then the actual work is less than that involved when pelargonium cuttings by the hundred have to be taken and housed.

Hardy annuals so seldom receive justice that to show them at their best is a legitimate reason for pride; the cornflower that is a lank, scanty leafed plant, usually becomes a fully-foliaged shrubby one, covered by blossom under good treatment; Lupinus Hartwegi ruber is a glorious cerise-crimson flower; Gilia coronopifolia, a three-foot biennial, best regarded as a half-hardy annual, gives profuse sprays of salmon-scarlet, while cerise and rose larkspurs of good strain are finer than many a cherished perennial delphinium in their profusion.

Annual climbers add immensely to the charm of the garden, either when used in conjunction with permanent ones or in their stead; the pillars of the verandah can be hung with the rosy-violet blossoms, and ultimately by the maroon seed-pods of the Purple Soudanese Bean, Dolichos Lablab, and convolvuluses of pink, white, and shades of blue. A quaint subject for trellises or clothing summerhouses is the Wild Balsam Apple, Echinocystis lobata, an exceptionally quick annual climber of the Gourd family; warm house-fronts, with wires stretched across, will do for the many-hued Japanese Morning Glories, Ipomæa imperialis, or the feathery-leaved red and white blooming Cypress vine, Ipomæa Quamoclit.

Of foliage plants, to soften bedding displays, or give height, there need be no lack; a choice can be made between the summer Kochia tricophylla, cockscombs, feathered celosias, beets, Atriplex hortensis atro-sanguinea, Ambrosia mexicana, amaranthuses, Lavatera arborea splendens, mesembryanthemums, Cineraria maritima, and cotton thistles, or onopordons that can be treated as annuals, with stately maizes, of heights varying from four to ten feet.

M. H.

Tuberous-rooted Begonias.—The tubers must now be examined and started. They may either be laid out in trays or placed on the border of a warm fruit house. When root action commences potting must be attended to, before growth becomes far advanced. A suitable soil is made up of two-thirds loam and one-third old hotbed material, mixing these together thoroughly. Another plan is to box the tubers in the first place and grow them on in the same boxes for planting. Boxes twelve inches wide, twenty-four inches long, and three inches deep, are used, placing a layer of leaves over the bottom and a layer of soil on this. About twelve tubers are placed in each box, and then soil is filled in, slightly covering the tops of the tubers. They are then stood in a warm house, and covered with paper, to prevent too rapid evaporation. When growtn is evident the boxes are removed to cold frames, eventually hardening the plants off as the time draws near for planting. This method saves a great deal of labour, and answers well. If possible a dull day is preferable for planting when this style of culture is carried out.—E. C. P.

DAPHNES.

Few shrubs are invested with greater interest than daphnes; their charm lies chiefly in their delightful fragrance, and, fortunately, this character is developed in a marked degree in the commonest and hardiest species. The genus embraces both evergreen and deciduous kinds; to the latter belongs D. Mezereum, a winter-flowering species, that blooms from January till March. The flowers are variable in colour, red, pink, and white being represented, the last-named in single and double forms; while in the type plant the flowers are succeeded by an abundant crop of berries that change to a bright red colour in autumn, and so invest it with additional interest at that season.

Daphne laureola and D. pontica are evergreen species, that develop into spreading bushes some three to four feet high; they form excellent undershrubs, and are valuable for making cover under trees where not much else in shrub life would succeed. The flowers in both cases are greenish-yellow, but not showy. Daphne oleoides (Fioniana) forms a small rounded bush some two to three feet in height, with dark green, box-like leaves and reddish-purple flowers, in clustered heads; these also are sweet scented. Daphne Cneorum (the Garland Flower) is one of our choicest rock shrubs, a miniature in growth, the branches being almost prostrate on the ground. The terminal points carry the clustered flowers, which are of the richest shade of pink, and most delicately perfumed, and in rounded heads. The variety major is that most generally grown in gardens.

Daphne Blagyana produces the largest and most conspicuous flowers of the genus; these are ivory-white in colour, and are borne in clustered heads on the terminal points of the previous year's wood. The plant is prostrate in habit, and it succeeds best when the branches are layered and pegged into the ground, so that they form roots, and thereby impart greater vigour to the specimen. Daphne Genkwa is a very rare and lovely deciduous species, only hardy in favoured districts or if grown against a wall and afforded some protection in winter. The flowers are lavender-coloured, and produced along the branches in spring before the leaves; it is one of the most charming shrubs possible to conceive. Daphne petræa (rupestris) is a quite rare plant, of pigmy stature, with scented pink blossoms of wax-like texture; it is quite hardy, but of slow growth, which adversely affects its increase, consequently the plant is generally difficult to procure.

Daphnes indica and odora are dainty evergreen subjects, most suitable for a cold greenhouse, as they are not hardy; both are most highly scented, and quite small plants are capable, when in bloom, of filling a room with perfume. Except the commonest species, which succeed in ordinary soil, daphnes prefer a cool medium made up of loam, peat, leaf-soil, and sand, and should have a sheltered site at planting, and if the position affords some light shade during midday this will favourably influence their free development in summer.

THOMAS SMITH.

Cucumbers.—Keep these well supplied with top-dressing as soon as the roots come through the soil. Keep the shoots regularly tied out and trained, and stop at one joint beyond the fruit. I find Everyday is still one of the best for early use and winter fruiting, the fruits being just the size wanted, and the plants exceedingly prolific. Sow again for succession. I believe in growing new batches instead of keeping old plants dwindling along over a long period.—W. A. COOK.

THE BEST PINK PERPETUAL CARNATIONS.

John Addington Symonds remarks in one of his essays on the "Colour Difficulty" that the range of hues is almost infinite, and that the range of words to describe these colours is strictly limited. It is an old difficulty. The artists have their colour chart, the milliners have theirs, and the florists theirs, all and each claiming to be the standard, so no wonder there is great diversity of opinion. Each thinks the other's chart is hopelessly wrong, and even quite a joke. However, some day we may all agree upon a single international standard.

The carnation is seen at its best in those glorious shades of pink which are unsurpassed in any other flower, for in the carnation we can get a perfectly even art shade of the most delicate tone. Purity of tone counts for so much in these days of colour refinement, and few pink flowers are of an absolutely pure shade, devoid of any magenta. But in carnations we are getting purity of colour, and this, indeed, is a great triumph.

All of us have a soft spot in our hearts for the pink trio—Miss Jolliffe, of England; Daybreak, of America; and Madame Therese Franco of France; and undoubtedly the blood of all three is perpetuated in our modern race. For we have Mrs. T. W. Lawson and Enchantress, as direct descendants of old Daybreak, and few existing varieties have not some Lawson blood in them. All this is the work of one man Mr. Peter Fisher.

It was the pink variety, old William Scott, which first really woke America up to the claim of the carnation, and for pure all-round merit it stood omnipotent until the introduction of Mrs. Lawson in 1900. It is a joy to meditate over the really great varieties which have gone to make the history of our modern flower: Madame Melba, Joost, Mrs. Theodore Roosevelt, Floriana, Ethel Croker, Alpine Glow, and a few American old-time favourites.

England also has some whose memory we are proud to recall. Pride of the Market, Duchess of Portland, Lady de Trafford, etc., have played their part, and it would be interesting to know the raiser's history of some of our old-time British varieties; for instance, who raised Miss Jolliffe?

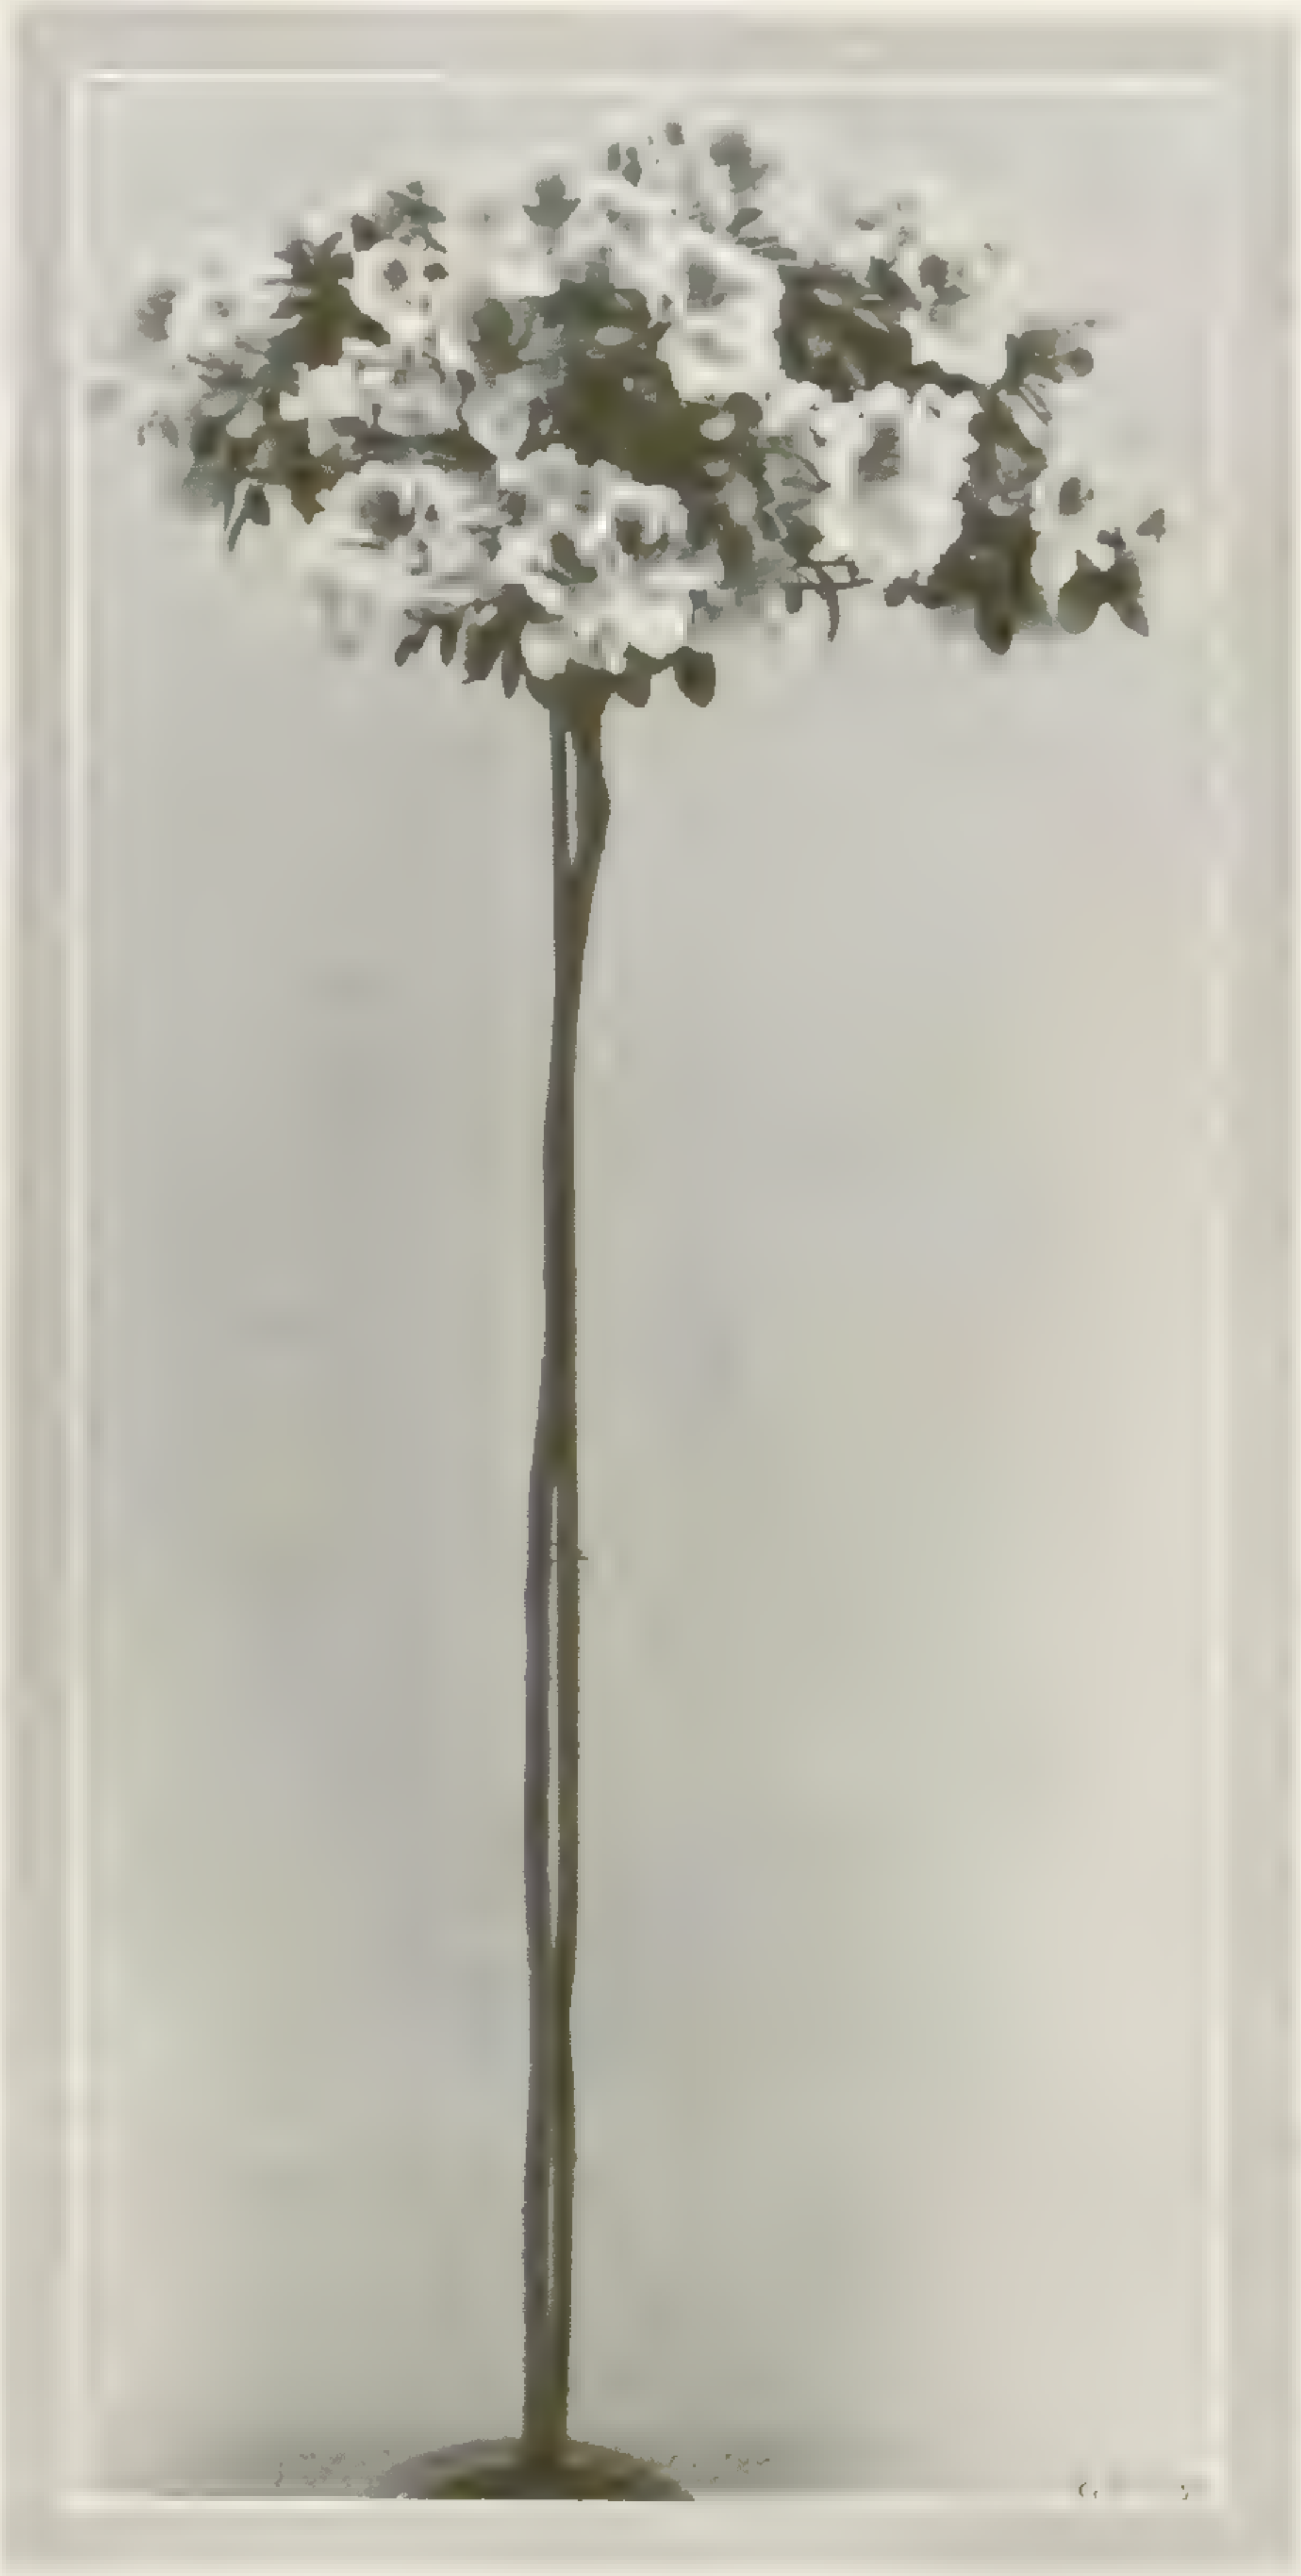
It is difficult to group up our many excellent present-day varieties, but we will deal with the light pinks separately from the dark pinks, and those of a salmon shade from the blue pinks.

Taking the light pinks Enhcantress still reigns supreme for size of flower and all-round quality. But that exquisite new variety, May Day, is to-day its greatest competitor. Yet both these excellent varieties have distinct charms, and the greatness of one does not rest upon the shortcomings of the other. May Day has quite a salmon tint, the flowers have smooth-edged shell petals, and it is undoubtedly the freest-flowering variety under cultivation, but then the blooms are not so large as those of Enchantress, and, alas! all too many count this a defect.

Pink Delight has many favourites, and deservedly so, for the flowers are of exquisite form, and of a delicate shell pink shade of colour, and they certainly catch one's eye at the shows. To my mind, its weakness lies in its habit of growth, which, although it is quick, is long and thin, not branching out and making a bushy plant. This variety is also difficult to propagate, so it is essentially a variety for good growers only. Admiration reminds one very much of Enchantress, except that the colour is several shades deeper. Personally, I believe this variety will be good in England. The variety Mrs. Charles Knopf has generally failed, whilst Fair Maid, Melody, Fiancée, etc., have been superseded.

Practically our only pale salmon-pink is Mrs. H. Burnett, and, while this variety may not be perfect, it is the best we have in this shade of colour, and it has played a very prominent part in popularising the perpetual carnation in England.

Flowers of a dark pink shade are never quite so popular as those of a paler tone, nevertheless they are essential. The best dark pink variety of to-day is Dorothy Gordon, one of last season's novelties. It might be termed an improved Rose-pink Enchantress, indeed some consider that it is simply a selected stock of that variety. That is an open question. It certainly has a more free growth, and flowers of a slightly darker and more even shade. Taking the more cerise shade of pink, Mrs. C. W. Ward, another of last season's varieties, can claim superiority over Afterglow, Aristocrat, Lawson-Enchantress, etc. The colour itself is not perfect, and has a slight magenta tinge, yet this is atoned for by a vigorous, healthy growth, and a perfect stem and calyx. Certainly every market grower should grow Mrs. C. W. Ward.



A STANDARD SPECIMEN OF AZALEA PROFESSOR WOLTERS.

A variety of Azalea indica, with single flowers, rose, bordered with white, and with deep salmon-rose centre.

Winsor, which undoubtedly is a sport from Mrs. T. W. Lawson, still continues in cultivation, and will remain to do so until we get an improved variety of similar shade. We must have this shade of medium pink, and old Florian lived on long past its prime on account of its perfect colour. Winona failed because it lacked size, and its soft growth was not suited to our climate, yet in certain parts it does well, and it still remains a favourite in America. It certainly is of a perfect clear shade. Rose Doré and Rival both have their votaries. The two flowers differ completely in build, but Rival comes a brighter and better colour in dull weather. There are other pink varieties, but we have mentioned the best of them, and how many bad ones we miss really does not matter.

The flood of new English and American pink varieties this season is certainly a heavy one. All cannot be the best, and which will survive out of Washington, Gloriana, R. F. Felton, Lady Alington, Rex, Bright Spot, Colossus, etc., we cannot yet say. Montagu C. Allwood.

STANDARD INDIAN AZALEAS

During late years there has been a very decided extension of the culture of Indian azaleas for conservatory decoration during the early months of the year, and this is not to be wondered at, because now-a-days the immense number of varieties of Azalea indica, chiefly of Continental origin, have given us a wonderful range of colours. Against the wide use of forced deciduous flowering shrubs there is not a word to be said, but their range of colour is comparatively limited, therefore the Indica azaleas possess merits which neither the private nor the commercial gardener can overlook.

In addition to the culture of bushy single-stemmed specimens, such as we are all familiar with, there has of late grown up a demand for, and trade in, tall standard plants. In the old days, when big specimen azaleas were a feature of the early exhibitions, the round-headed and the pyramidal methods of training were mostly followed, but standards, though not absent, were by no means common. Even at the great Continental displays in the springtime standard Indian azaleas have not been numerous until quite recently. In other directions, too, the value of standard flowering shrubs has been amply demonstrated, and there is now a growing annual demand for standard-trained plants of lilacs, Ghent and Mollis azaleas, wistarias, laburnums, staphyleas, prunus, etc. The great value of these standards, whether of Indian azaleas or other subjects, lies in their utility for grouping with totally different subjects, or with lower growing and bushy specimens. In the case of the Indian azaleas, the standards now so frequently seen possess heads of medium size, full of bloom, and born on stout stems, 3ft. to 5ft. high. In the illustration here given, a specimen of the brilliant variety Professor Wolters, is depicted, as exhibited among similar plants of many other varieties by Messrs. J. Veitch and Sons, Chelsea.

Forced Strawberries should be fed with liquid manure water made a little warmer than the temperature of the house. The fruits must be raised as they increase in weight, and this is best done by means of wire supports that are fixed to the pots. These hold up the whole crop, are easily adjusted, and last for years. Syringe well twice daily to keep down red spider. The second batch now coming into flower should be given air on all favourable occasions, especially when the sun is shining, and it should be given early, before the house is stuffy. In the afternoon, at closing time, a gentle spray will benefit them and cause them to set freely and well; all deformed fruits should be removed at once, and the crop thinned to from nine to twelve fruits per plant. Give abundance of air to successional plants, and draw the lights entirely during the day from those in frames.—W. A. Cook.

PERNETIANA ROSES.

The three articles from the pen of the Rev. J. H. Pemberton upon this section of roses have been very instructive, and I hope the following notes may be appropriate.

There have been many disappointments and some serious complaints about the behaviour of Rayon d'Or, the gold medal variety at the Regent's Park Exhibition of the National Rose Society last year. Mr. Pemberton gives us a most graphic description of this marvellous rose on pages 107-8 of the Gardeners' Magazine, and I cannot add to it; except to say the only flowers I have seen were superb in their colouring. But I wish to refer to the great difficulty in propagating this rose. One friend, who has the most up-to-date conveniences, put on over 1,000 grafts, and, in spite of skill and more than usual care, because of the indifferent character of the wood and the expensive variety, he only succeeded in keeping six alive, and these far from flourishing. In some cases all have died.

Keeping to the matter of propagation, I may say we find the wood of all Pernetiana roses (an excellent list of which Mr. Pemberton describes) exceedingly difficult to use successfully for grafting. We experienced that with the older varieties, Austrian Copper and Gottfried Keller, when trying to increase a somewhat depleted stock. Even wood from pot-grown plants is far from satisfactory with any of this section. Nor will they root freely from cuttings. We also find the same difficulty with the Penzance sweet briars, Lady and Lord Penzance, which resulted from crosses with the Austrian Copper and Austrian Yellow roses and the common sweet briar; so that it seems fairly certain this section is impatient of heat, more especially as regards wood for grafting.

Mons. Pernet Ducher wrote me recently that he also had this difficulty, such as he, with all his years of experience, had not hitherto known. A soft, sappy wood, made worse than usual by the wet season of 1910, was unable to stand the winter. We know, too, that Soleil d'Or is much subject to black spot on the foliage, and the raiser writes me it was very bad there last autumn. Then Melaine Soupert, the other parent of Rayon d'Or, is rather a soft grower, and does not stand the winter well. Still, I believe we shall find Rayon d'Or a general favourite when established and some sounder wood made, for even if cut down, the base can be protected, while it is such a glorious colour we must have it, as well as several other varieties difficult to grow.

Budding seems the best form of propagation with this class, and fortunately the growths carry plenty of buds, and generally with a good "seat" to them.

A. Piper.

PEAR BEURRE BALTET PERE.

Comparatively few nurserymen catalogue this particularly large and handsome pear, and yet it is a variety worthy of consideration, especially by those who have to provide fruits during November. Under good cultivation Beurre Baltet Père, whether grown as a pyramid or cordon, produces fruits of great size, so that a well-cropped tree presents a fine picture. In addition to being handsome and large, this pear has the great merit of being a free and heavy bearer, and thus it will appeal to many. Then it also possesses good flavour, indeed, some authorities go further and give its quality as "excellent." Fruits are ripe during November, the specimen figured herewith is one of many fine examples grown by Mr. J. Whittle, gardener to Colonel Barton, Cheveney, Maidstone, and so successfully exhibited by him at the Royal Horticultural Hall last autumn.

PEAR BEURRE BALTET PERE.

Summer-flowering Chrysanthemums.—Assuming the cuttings are well rooted, they may now be transferred from the cutting boxes into cold frames. About six inches of good soil should be placed in the frames, and the plants put out six inches apart each way. The frames should be kept fairly close and shaded, and the plants damped overhead occasionally until they recover themselves. Here they will make excellent stuff for putting out in April.—E. C. Pooley.

NOTES FROM HERE AND THERE.

I do not suppose that knotty question as to whether a young fruit tree should be pruned the same season it is planted or a year later will ever be settled to the satisfaction of everybody, and I do not know of any topic in fruit culture that has been discussed more. Generally speaking, however, I think practical fruit growers decide the matter for themselves as the result of their own experience, and it happens in this way. A man plants trees, prunes them, as advised by our friend Mr. Coomber on page 71, when their buds commence to swell, and gets satisfactory growth as the result. This man becomes a first year pruner at once, and is prepared to argue the wisdom of it as long as you like; but another man prunes his trees the first year, and if they start to grow at all they only push weakly shoots that are entirely unsatisfactory. His faith in first-year pruning is shaken, he leaves his next batch of trees for a year before shortening them back, and gets good heads. From that time henceforth he is convinced that second-year pruning is the best, and it is in this way that the two shades of opinion become so fixed.

What becomes of the thousands of standard apple trees that are propagated in nurseries and distributed every year? A great many of them flourish and become fruitful, and contribute in time to the domestic or commercial fruit supply of the country, but not all, and it would be interesting to know how many of the young trees sent out from nurseries die an ignominious death through sheer lack of attention. Just by way of illustrating what I mean, I happened to be in an orchard the other day where a couple of years ago a matter of fifty young trees were planted to fill up vacant spaces, but the job was only half done, for no proper stakes or means of protection were provided. Cattle rubbed against the trees, horses broke the lower branches, rabbits gnawed the bark from the stems, and to-day I do not suppose there are ten of the fifty trees alive. The trees cost half-a-crown apiece, and to all intents and purposes those half-crowns were simply thrown away because a careless individual did not think it mattered about staking and protecting the specimens until it was too late, and their doom was sealed.

In his article on page 75 Mr. E. Molyneux tells of a fruit grower who does not believe in alkali winter washing at all, but prefers to spray in the spring with lime and salt. Quite so, and it would have been interesting if Mr. Molyneux had also given us the reason why the grower in question prefers lime, having, I presume, tried both, but it may be observed that a great many commercial growers prefer the lime spray to caustic alkali washes, and it is not unusual now to see orchards and plantations in the spring snow-white in appearance as the result of lime-spraying. It will be readily admitted that alkali washes in the winter cleanse trees from moss and lichen, but do they do anything more? Advocates of lime-spraying urge that this material is as effectual as the caustic wash in cleaning trees, and it also seals the eggs of certain injurious pests to the branches so that they cannot hatch out. Lastly, whatever may be said about caustic washes injuring the trees, and there are strong views on the subject, lime is harmless, and every bit that peels off the trees and falls to the ground is beneficial.

One meets with curious instances sometimes of the way difficulties are got over in the gardening world, and successes are achieved by men whose facilities are of a very limited nature; for instance, the other evening I was adjudicating at the monthly meeting of a gardening society composed mostly of working men, where, amongst other things exhibited was a very nice bunch of blanched seakale which would have done credit to a gardener and a forcing pit. No professional man, however, had had any hand in producing it, for the seakale was the property of a labourer, and he told me with some show of pride how he had grown it in a box under the stairs in his cottage. But what does a cottager want with seakale? perhaps some would ask, but surely if a cottager likes to grow a bit of seakale for his own consumption there is no reason why he shouldn't. I may add, however, that in this case the man has other objects in view, and the seakale forced under the stairs brings in a little money which helps to pay for other things.

Years ago, in my early gardening days, I used to read articles from the pens of able men descriptive of the way asparagus beds should be made in order to grow this delicious vegetable satisfactorily, and I thought then what an elaborate process it all was. Since then, however, I have learned that Nature has made certain soils suitable for asparagus which many gardeners, if they inspected it, would condemn as impossible. Business takes me frequently to a district on the borders of Worcester and Gloucester, where the soil is so heavy and retentive that four or five horses are required to draw a plough, and with this strength the pace is slow. The allotment holders turn up the clayey lumps with heavy two-pronged forks, but asparagus is the most profitable crop they can grow on their plots. The crop is grown on ridges or raised beds, with alleys between, soot is the principal fertiliser used, and in the season fine heads of "grass" are obtained. Does not this all go to show how Dame Nature adapts vegetation to varied conditions of soil.

It has been announced by a prominent daily paper that the sweet pea is to be the "Coronation Flower," and whether this proves to be the case or not, it is quite safe to prophecy that it will figure very conspicuously in this auspicious year. I have heard the public fascination of the sweet pea spoken of as a passing craze, like roller skating and ping-pong, but it seems more like lasting than passing, and the taste for the flower is by no means confined to the people who are recognised as leading lights in the sweet pea world. It falls to my lot to move a good bit amongst cottagers and amateurs possessed of limited means and resources, and their keenness to get hold of the best varieties as well as unstinting efforts in labour and trouble to produce first-class flowers are both encouraging. It is true the man who in these days half fills his back garden with sweet peas does not, as a rule, aspire to winning honours at national shows, but there is no village exhibition without its sweet pea classes, and there are no classes in which competition is keener.

We have again arrived at the time of the year when the buds of plums, pears, gooseberries, and currants provide a dainty morsel for various members of the feathered tribe, the worst of which perhaps is the bullfinch, and again the old, old question crops up as to the best means of checking the birds and saving the buds. In private gardens the bird plague is a real one, but it is even more so where the commercial grower is concerned who has to depend on fruit for his living. In that well-known fruit-growing county, i.e., Kent, sparrow clubs are established institutions in many villages, and during the winter season the members of these clubs wage war on the birds that are injurious to fruit crops, but outside Kent organised sparrow clubs are not very general. Nowadays, however, a good many commercial growers are turning their attention to lime-spraying as a means of protecting crops, the idea being that by spraying the tree with lime wash the buds are made distasteful to the birds. If any readers of the Gardeners' Magazine have tried it they might be good enough to recount their experience.

One of the most familiar flowers to be seen about just now is that of the Silver Wattle (Acacia dealbata) which goes by the name of Mimosa in the streets, and is offered for sale by itinerant flower sellers along with bunches of blue violets. There seems to be a connection between the two, and the bright yellow flowers of the Silver Wattle gives reminders of the Riviera where the tree grows profusely, and one wonders where the flowers come from in such quantities as to allow of their being offered by every flower hawker in the street at a figure which is far from being prohibitive. Perhaps if the Silver Wattle flower had not been made as familiar and commonplace by flower-sellers it would be prized more in gardens; but now and then you come across plants furnishing pillars in greenhouses and conservatories, and nothing in the early months of the year could be more attractive, particularly if the main shoots are fastened to the pillars and the growths made last season, which produce the flowers, are allowed to grow in a loose and natural manner.

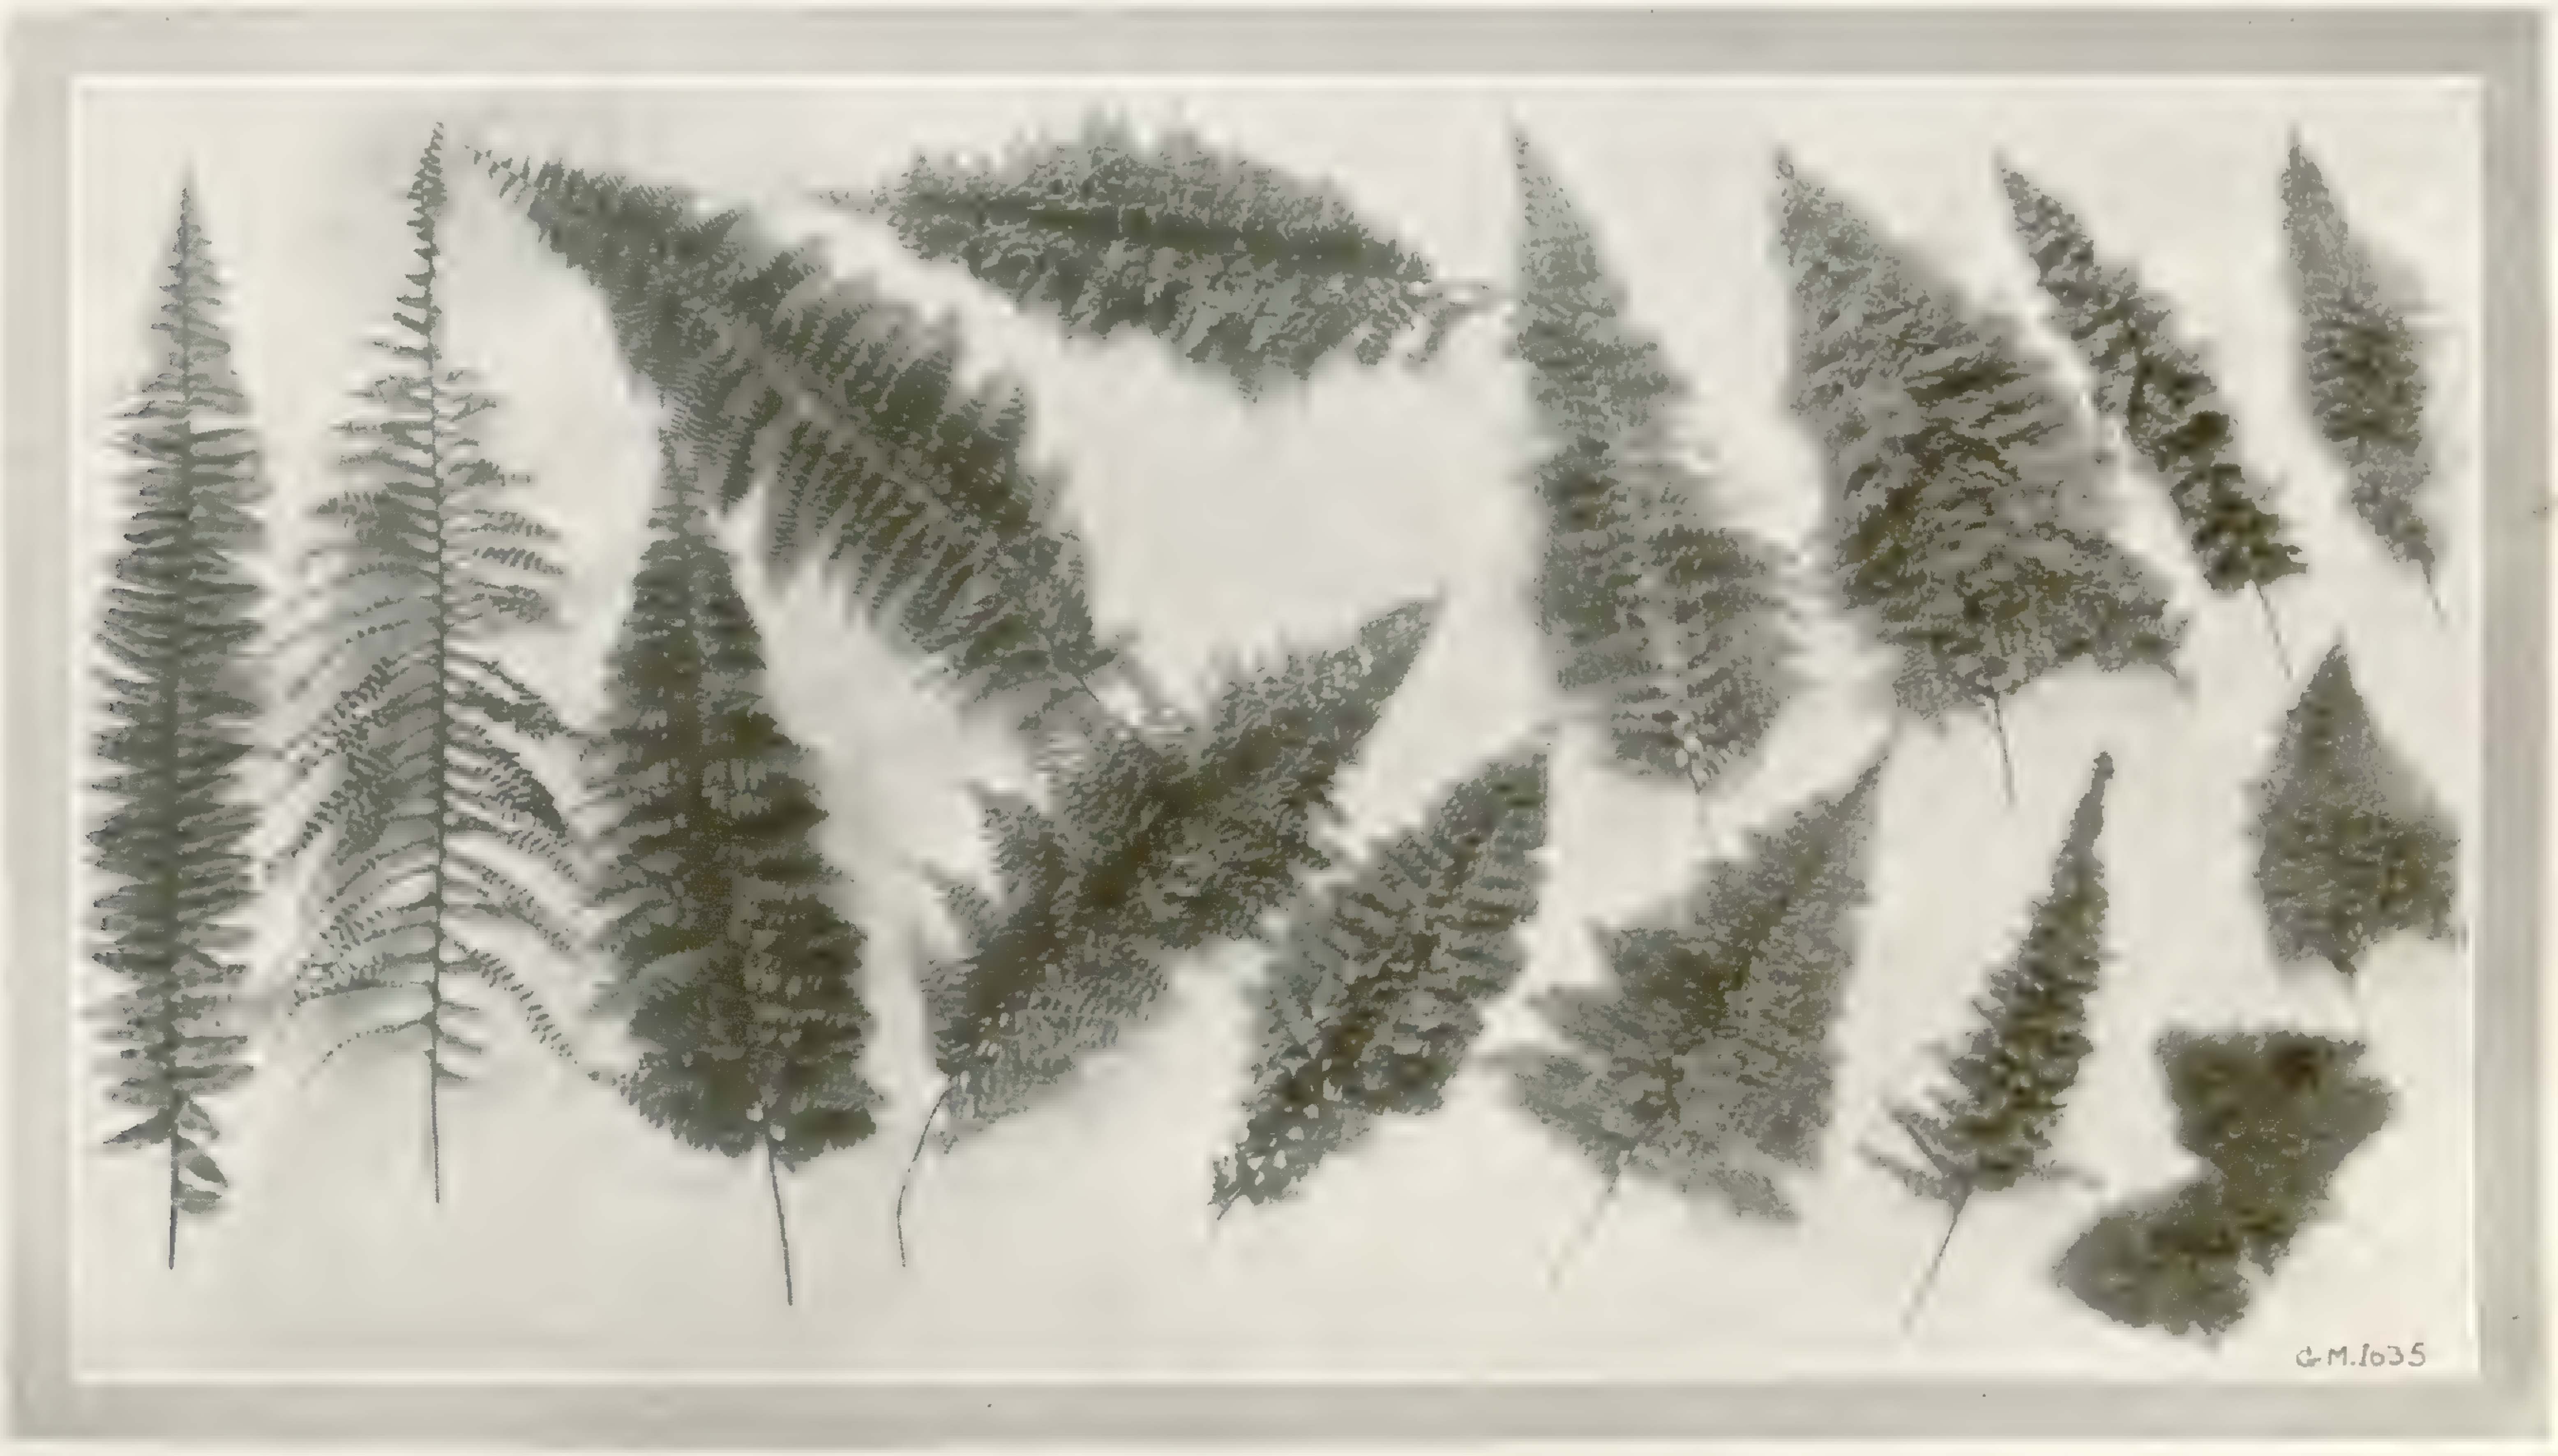
H.

Roses.—In most localities it is quite safe now to commence pruning operations among the hybrid perpetuals. The more tender varieties should be left until the first week in April. These include teas, hybrid teas, Chinas, and noisettes. No hard and fast rule can be made as to the exact dates of pruning; this must be decided according to the district. The weak-growing varieties should be pruned closer than the stronger ones, and the centres of all plants should be kept fairly open. In dealing with the dwarf or bush plants of strong habit about four or five buds should be left, and less on the weaker ones. A sharp knife should be used for the work, and the shoot cut immediately above a bud which will grow outwards. On no account should secateurs be used, for the wood is bruised by the practice, and often decays after pruning. It is advisable when pruning established plants to cut one or two shoots close to the base to prevent the stems from becoming bare. If this is practised annually, a bushy habit will always be retained, otherwise the plants will in time become leggy. The shape of the heads of standard trees must be taken into consideration when pruning, and in other respects the same advice applies as given for the dwarfs. When the practice of pegging down is carried out the maiden wood should be left much longer, and some of the older growth removed. When pruning is completed a mulch of decayed manure should be given the beds, covering it with a layer of soil.—E. C. Pooley.

THE VARIATION OF NEPHROLEPIS EXALTATA.

One of the wonders of horticulture is the manner in which that old and popular fern Nephrolepis exaltata has developed new and varied graces during the last dozen years or so. It is not an easy matter to trace the genesis of some of the exquisitely beautiful forms now before the public, but in the earlier stages of plumose development our American friends were very keen and successful. Every slight variation has been eagerly watched, and the sporelings raised subjected to close scrutiny and selection; so that now there are at least a dozen distinct and beautiful varieties, showing various degrees of sub-division and of plumose or moss-like development.

Very instructive was the exhibit recently made by Messrs. H. B. May and Sons, of Edmonton, at the Royal Horticultural Hall, and herewith illustrated. It consisted of sixteen full-sized fronds of these wonderful ferns attached to a paper-covered board, and so disposed as to show the evolution from N. exaltata proper to the exquisitely elegant variety named Marshalli compacta, seen at the bottom right-hand corner. In order of plumose development, the varieties were: Fosteri, Piersoni, Barrowsi, elegantissima, elegantissima compacta, todeaoides, Whitmani, Amerpohli, superbissima, magnifica, Scholzeli, lycopodioides, Marshalli, and Marshalli compacta. The last two were raised by Messrs. H. B. May and Sons. The extreme elegance of these lovely ferns is one cause of their immense popularity—they are grown by hundreds of thousands for market—while another and very important cause is the fact that these ferns will last a very long time in a dwelling-room if given reasonable attention as to watering; indeed, few ferns are so well suited for home decoration.



THE VARIATION OF NEPHROLEPIS EXALTATA.

This illustration shows in a remarkable manner how, under skilful cultivation and selection, a common greenhouse fern has been developed, through many stages, from the type on the extreme left to the beautiful, much-divided, plumose, and compacted forms on the right.

SOME INTERESTING CONIFERS—II.

◆

Libocedrus decurrens.

Standing sentinel-like amongst other trees, the stiff, columnar outline of this species commands attention, and it is rarely that a well-grown example fails to obtain appreciatory notice. A native of the Southern United States, it is met with in mountainous regions from Oregon to South California, at no great distance from the coastline. Its introduction into English gardens is said to date from 1853, the credit of its introduction being awarded to John Jeffrey, who collected for the Scotch Oregon Association. In various parts of this country fine examples may be found, several very good ones occurring in the grounds at Frogmore. There are, however, no prospects of British-grown trees attaining the magnificent proportions of the finer native specimens, for travellers report them as being from 130ft. to 150ft. high, with trunks 6ft. in diameter near the base. Grown in the open, the branches clothe the trunks from a low point; but under forest conditions clear boles of 60ft. may be obtained. The wood is possessed of moderately good economic properties, and is known as Incense Cedar. For gardens of restricted area this tree offers advantages for it causes little inconvenience to surrounding vegetation. The leaves are of a peculiarly dark shade of green, which alone stamps the tree as distinct. The only other species of libocedrus which approaches it in hardiness is the Chilian—L. chilensis.

Sciadopitys verticillata.

The Parasol, or Umbrella, Pine of Japan is an exceedingly interesting and distinct tree. It cannot be said to possess any features which suggest a close relationship with any well-known conifer, for it is amply distinct in every way from any pine, a family with which its common name might be considered to suggest a close tie. The common name arose on account of the whorls of flattened leaves being considered to bear a resemblance to the ribs of an umbrella. In Japan the tree attains a height of 100ft. or thereabouts, with a considerable girth. According to Veitch's "Manual of the Coniferæ," the first living plant introduced into England was received at the Exeter Nursery in 1853, Mr. Thomas Lobb having obtained the plant from the garden of the Dutch Governor of Java. Subsequently it was sent home about 1861 by Mr. J. G. Veitch and by Mr. Robert Fortune. The tree is of pyramidal outline, with whorls of twenty-five or thirty flattened, dark green leaves, each of which is three or four inches in length. The buds and young bark are of a bright brown colour. The cylindrical cones are usually from 2in. to 3in. long, and 1½in. to 2in. in diameter. They take two years to mature and produce an abundance of fertile seeds. They sometimes have the peculiarity of bearing a leafy shoot from the apex. It is wise, however, in most instances to remove both male and female flowers before they have an opportunity to expand, in order that all possible vitality may be centred on the building up of the tree. Light soil appears to be more suitable than that of a tenacious character, whilst a mixture of peat and sandy loam suits the tree admirably. A position sheltered from cold winds is desirable, whilst shallow planting is to be recommended. Should a number of leaders appear, which is frequently the case, all but one should have their points removed to encourage the central trunk.

Cunninghamia sinensis.

This is only suitable for the Southern Counties, for, though it lives through mild winters further north, it is not to be relied upon, and a spell of severe frost is likely to seriously cripple it or kill it outright. In Devonshire and Cornwall it may form a tree 40ft. to 50ft. high, with a trunk 1ft. to 15in. in diameter. The branches and leaves somewhat resemble those of some of the araucarias, particularly A. brasiliana. The leaves are lance-shaped, up to 2in. long, pale green above, with two silvery stripes on the under-surface. The cones are small and round, and are produced freely in Devonshire. The plant has been in cultivation upwards of a century, for it was introduced from the South of China about 1804.

Fitzroya patagonica.

This is one of several evergreen trees which inhabit the wild, mountainous regions of Western Patagonia, Chili, and Valdivia. Its distribution is said to extend southwards to the Magellanic region, where, however, in the exposed country which is subject to violent storms it forms but a scrubby bush. In its most favoured localities it is said to form a moderate-sized timber tree, but the difficulty of extraction is so great that the timber is not a marketable commodity. For the warmer parts of the country it is an excellent tree to grow, as its slender and more or less pendulous secondary branches, which are clothed with whorls of tiny leaves, are of a peculiarly graceful character, imparting to the tree a most distinct appearance. It thrives in light soil, both loamy and peaty, and appears to have a preference for gardens near the coast, where the atmosphere is humid and the climate fairly equable. The common name of Patagonian Cypress has been given to the tree. A second species of Fitzroya, F. Archeri, is known. This is a native of Tasmania, but is very rarely seen in cultivation.

W. Dallimore.

EARTHWORMS.

It was Darwin who first suggested that wherever the common earthworm (Lumbricus) finds the conditions of existence it exerts a most important influence in the formation of humus in the surface soil layer, and the limitation imposed upon these conditions by the subsoil has doubtless a great deal to do with the sharp demarcation we often find between it and the surface soil. Briefly stated, the earthworm nourishes itself by swallowing successively portions of the surrounding earth, digesting a part of the organic matter, and then ejecting the undigested earth in the form of "casts," such as may be seen by thousands on the surface of the ground during or after a rain.

Darwin calculated, from actual observation, that in humid climates and in a ground fairly stocked with these worms, the soil thus brought up may amount to from one-tenth to two-tenths of an inch annually over the entire surface, so that in half a century the entire upper foot might have been thus worked over. Aside from the mechanical effect thus achieved in loosening the soil, and the access of air and water permitted by their burrows, the chemical effects resulting from the digestive process of worms, and the final return of their own substance to the soil mass, also their habit of drawing after themselves into their burrows leaf stalks, blades of grass, and other vegetable remains, renders their work of no mean importance, both from the physical and chemical point of view. The uniformity, lack of structure, and loose texture of the surface soil, especially of forests, as compared with subsoil layers of corresponding thickness, is doubtless largely due to the earthworms' work. It has frequently been observed, says Professor Hilgard, that when an unusual overflow of water has drowned out the earthworm population of a considerable area of land the surface soil layer remains compacted, and vegetation languishes until new immigration has restocked the soil with them.

Dr. E. J. Russell, of the Rothamsted Experimental Station, has recently been carrying out some investigations on "The Effects of Earthworms in the Productiveness of Soils," from which he considers that previous investigators have been misled by the nitrogen introduced in the bodies of the earthworms themselves, for when this is allowed for they seem to have no particular effect on the decomposition of organic matter and the production of nitrates. They have, however, considerable effect as cultivators, loosening and mulching the soil, and this may ultimately have an action upon its fertility, though experimental demonstrations would be difficult.

J. J. Willis.

MELONS AND MANURE.

I was pleased to see Mr. W. A. Cook recommending the use of mushroom-bed manure as a part of the compost for melons, as I have too often heard persons advocate the none-use of manure for the growth of them. As a rule, the advice is "pure turfy loam, with the addition of some old lime rubble," as a sufficient compost for melons, and even when soiling over the roots on the hillocks loam only is advocated. With this teaching I do not agree, as I know from experience the plants under such conditions do not develop growth nearly vigorous enough to bring out the full merit of many varieties of melons, neither do the plants crop so well, or produce such fine fruit. I do not advocate the growth of huge fruit, but I do like to see representative fruit of all varieties. For instance, Hero of Lockinge, which is perhaps the melon of all others that has stood the test of time, and is to-day more grown than any other variety, does not present the same rich skin, fulness of netting, and general excellence when undersized fruits only are obtained, as compared with the deeply-crinkled exterior and rich flesh and delightful flavour when grown and ripened under generous culture.

Many growers are apt to think the flavour is not of the same richness when manure is employed in the growth of the plants; that, however, is more fanciful than real, because by the time the fruit is finishing the ripening process, the plants are not so dependent upon the root action as they were when in active growth. A small quantity of manure mixed with the loam at the time of sowing the seed in the small pots induces a vigorous growth right away from the start. Weakly grown plants cannot give the same results in growth, crop, and economy of time as those of a more robust character. The sooner the growth is complete the more economy is practised. No one wishes to occupy a house with a melon crop for five months if four is sufficient. A well-managed house will produce three crops in a year.

It is surprising what a filip is given to the growth of melon plants if the surface roots on the hillocks are lightly covered with cow dung, and occasionally watered with weak liquid manure.

E. Molyneux.

BEST PLANTS FOR GREENHOUSE.—Nearly 300 pages are devoted to the description, propagation, and culture of the best flowers and plants for the greenhouse in The Amateur's Greenhouse, by T. W. Sanders, price 5s. net, or by post 5s. 6d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

THE FUTURE OF THE SCOTTISH HORTICULTURAL ASSOCIATION.

(Concluded from page 193.)

◆

THE YOUNGER MEMBERS.

There is another aspect of our work which, I think, does not receive sufficient attention from us, and that is our interest in the younger members of the association. The young members do not, as it seems to me, take a large enough share in the work. It is to them that we must look to carry on the work of the association after those of us who are now in the seer and yellow leaf have fallen out of its ranks, and I think they should lose no time in buckling on their armour and entering the lists. About a dozen years or so ago, there was in existence in connection with this association what was called the "Junior Horticultural Association." This was composed of young men who were members of our association, who formed themselves into this body for the purpose of reading papers and conducting debates, and the association lasted for several years. I do not advocate the reformation of such a body, but I do think that the young members should have more consideration at our hands, and in order to give them facilities for the reading of short papers, the Council have, at my suggestion, arranged to give up the April meeting this session to their exclusive use, and I appeal to them to come forward and take their legitimate share in the work. Many sermons have been delivered to the youth from this chair. I do not propose to preach at them, but I do invite, nay, urge them to take a fuller advantage of our meetings in training themselves to giving intelligent reasons for the faith that is in them. In order to give a stimulus to the project, I may say that the Council have arranged to offer prizes in books to those who acquit themselves most creditably at the April meeting.

As regards the teaching of horticulture, which is referred to in some of the past president's address from which I have quoted as a thing which this association should take a part in, I am of opinion that, while we no doubt should keep a watchful eye on what is being done in the matter, we should have no active hand in it. The time for this association taking up teaching as part of its work has gone past. We have now an Agricultural College in Edinburgh in which horticulture is taught by an efficient staff, and it would only be waste to overlap the work of the college in any way. There is one thing in connection with the teaching of horticulture in which it seems to me this association might be of use to young gardeners. The time is not far distant, we hope, when the Edinburgh and East of Scotland College of Agriculture, to the governors of which your Council have already made a representation on the subject (which has been courteously responded to), will institute a diploma in horticulture, and this will meet the case of all those who have the time and the means to go through a prescribed curriculum of study in the college. There are many working gardeners who have neither the time nor the means to attend prescribed courses of lectures in the colleges, and who must perforce pick up their technical knowledge in any haphazard way they can, to whom some hallmark would be valuable, and it is in such cases as these that this association might be of some service by granting to them certificates of proficiency. This, of course, would involve an examination by competent examiners in the theory and practice of horticulture, but it would in no way overlap or interfere with the work of the colleges; it would, in fact, benefit them, for many of these young men would be induced thereby to take advantage of the evening classes in these institutions, and this association might also materially assist in this by granting small bursaries to deserving young men, so as to enable them to take advantage of these classes. By instituting lectures on horticulture and allied subjects, this association has done a great deal for the technical training of gardeners in the past, and it would not be at all inappropriate were it now to take up this question of granting certificates such as I have described.

BENEVOLENT FUND.

There is just one other matter to which I wish to refer before I close, and it is one which, I think, deserves serious consideration, as in the case of the other subjects I have touched upon. It is the question of aiding the widow and the fatherless, and those who, through no fault of their own, have met with misfortune amongst the gardening fraternity. I am not prepared now to go into the details of such a scheme, for it would require a great deal of careful thought and consideration before it could be launched, but I for one feel that it is a scheme which should be faced, and I am sure that if it were gone about in the proper way, it would succeed. I have frequently noted a generous spirit amongst you in the voting of doles from the association funds for various benevolent purposes, but I am strongly of opinion that these contributions should come direct from the pockets which we individually control. We have, of course, great charities like the Gardeners' Royal Benevolent Institution, and the Royal Gardeners' Orphan Fund, both of which are doing splendid work, but the sphere of the former is restricted to the relief of the aged, distressed, and disabled gardeners and others, and their necessitous widows; and that of the latter to the relief of the orphans of gardeners and others. In the case of the Gardeners' Royal Benevolent Institution, the only persons who are eligible for the pension are those who have been head gardeners, or their foremen, market gardeners, market growers, nurserymen, and seedsmen, and foremen of nurserymen and seedsmen, and the widows of such persons. To be eligible gardeners must have served in the capacity of head gardeners, or their foremen, in the establishments of ladies or gentlemen for thirty years, and the foremen to nurserymen and seedsmen must have served as such for the same number of years. Market gardeners must have cultivated not less than five acres of land for thirty years, and market growers, nurserymen, and seedsmen must have been regularly engaged in the business for thirty years. Further, unless totally incapacitated through accident or incurable disease, no person is eligible for the pension under sixty years of age. No provision is made for the relief of distress in the case of the large army of younger gardeners and their widows in this charity. In the case of the Royal Gardeners' Orphan Fund, the beneficiaries must be the orphans of gardeners, foremen in gardens, or managers, or departmental foremen in nursery or seed establishments. We have also in operation now a State Old Age Pension scheme, but as no one is eligible under this till he or she is seventy years of age, it, like the Gardeners' Royal Benevolent Institution, of course, does nothing for the young or middle-aged, who may require pecuniary assistance to tide them over a period of distress. Such a fund as would aid the journeyman gardener and those dependent upon him when misfortune overtakes him in early or middle life, is a desideratum, and I think we should make an effort to have a benevolent fund of this sort instituted for Scotland.

To summarise what I have said, I have now to put before you the following definite proposals for your consideration, and I trust you will see your way clear to accede to them.

(1) To start a fund to provide for a horticultural institution, to contain at least a library, and reading room, hall for meetings, and suitable offices and other accessories.

(2) To readjust the finances of the association and of the chrysanthemum exhibition.

(3) To adopt means for the encouragement of the younger members to take a larger share in the work of the association by providing more facilities for the reading of papers, and for discussions amongst themselves, and by offering prizes to those who acquit themselves with most merit; and by instituting examinations and granting to young gardeners certificates of proficiency in theoretical and practical horticulture.

(4) By instituting a Scottish Benevolent Fund for the behoof of the gardeners and others, and their widows and children.

Manettia bicolor.—If any greenhouse climber possesses the merit of continuous flowering it is this little twining plant from the Organ Mountains of Brazil, for under favourable conditions it is very rarely out of bloom, spring, summer, autumn, and winter being all alike to it. The slender shoots twine themselves around any support, and in this way they quickly mount upward. The leaves are small, lanceolate in shape, and of a deep green colour. From their axils the flowers are produced. They are tubular in shape, and in colour bright scarlet tipped with yellow, a combination of colours which is very conspicuous at all seasons, but especially during the dull winter months. For blooming at this season the warm end of the greenhouse suits it best. Though generally known by the above name, it is sometimes met with as M. luteo-rubra and M. inflata.—W. T.

LEEKS.

Leeks require to be sown and treated much in the same way as onions during their early stages of growth, and the same rules should be observed in the selection of good stocks. The leek is a most popular and wholesome vegetable, especially when at its best. The chief point to consider in perfecting good leeks is blanching.

Trenches should be prepared and heavily manured much in the same way as for celery, and the drawing up of the length of stem required should be proceeded with immediately the plants are put out in April. This is best assured by using stout paper collars, which should be drawn up as the growth advances until the desired height is gained, allowing the stems to swell after length is attained. By following this practice the produce will be entirely free from grit, and present a beautiful white appearance. Copious supplies of water, both at the root and overhead, should be given during the summer months.

There are several very distinct and estimable varieties now grown, and among the best are Prizetaker, International, and Improved Lyon. E. Beckett, V.M.H.

SOME SPLENDID EXAMPLES OF PRIZETAKER LEEKS.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

CALANTHES.—The deciduous calanthes will now be producing their new growth, and as soon as these begin to show their roots the plants should be potted without delay, because, if the new roots are permitted to advance far before potting is done, they are the more subject to injury in the process. It is not so difficult where the plants have been turned out of their pots and rested in boxes on a bed of moss and sand, but there is always a possible danger of injury to new roots when the old material has to be removed just before potting.

POTTING MATERIAL.—Different composts are advocated for calanthes, and I would advise successful growers to continue on the lines they have found most suitable. I have found from experience that we are compelled to find out what is likely to be the most suitable compost under different conditions and situations in various parts of the country, and even different modes of treatment are required in certain districts. We find with all the inbred hybrids, where there is a tendency to weakness of constitution, that a lighter potting compost is required than that which is in general use for the more vigorous kinds. For the latter we use a compost of about equal portions of fibrous loam, peat, and sphagnum moss, freely intermixed with sand, broken crocks, and charcoal. For the more weakly ones we discard the loam altogether, and find that a few broken oak or beech leaves suit them better than the heavier compost.

AFTER REPOTTING very little water need by given until the new roots have become established; after this more liberal treatment may be afforded. The plants should have every encouragement to grow freely in a warm, moist atmosphere. It is an advantage to get the plants into growth as early as possible in the spring, as the summers of late have been all too short, and I am convinced that the early matured growths are not nearly so liable to be disfigured as the later ones.

PHAIO-CALANTHES. — The bigeneric hybrids that have been raised from the intercrossing of phaius and calanthe, cannot be regarded as deciduous plants. Some of them are undoubtedly semi-deciduous, and must be treated as such, and these require similar conditions to the calanthes in regard to potting and general treatment. The heavier compost mentioned above is suitable for them. These plants are best treated by growing several together in a pot, as a single scape of flowers is not effective. They are best repotted when they commence to emit roots from the base of the advancing new growths. They require an ample root room, as they are vigorous rooting. The pots should be clean and filled to about one-third their depth with drainage. Pot moderately firm, and if a thin layer of chopped sphagnum is placed on the surface of the potting compost, it adds to the appearance of the plants.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

GARDENIAS.—The present date is a seasonable one for rooting a batch of plants to give autumn and spring flowers. Gardenias revel in abundance of heat and moisture, and from the time the cuttings are rooted until they have completed their season of flowering they should be kept steadily growing. As the pots become filled with roots give an alternate supply of weak soot water and diluted farmyard liquid. The successful cultivation of gardenias is comparatively easy when grown either as pot plants or as planted-out subjects in a permanent bed. Where space is available the latter method may commend itself, as less labour and attention are required. I have a decided preference for growing gardenias in pots, as I think they are more easily kept in a free-flowering stage than when allowed more rooting space. In either case it is essential to employ good fibrous peat and loam, with a liberal supply of mortar rubble and broken pieces of charcoal to render the material open and porous. I must not omit what I consider the most essential item in the successful culture of gardenias, i.e., they must at all times be kept clean, and free from red spider and mealy bug; here the advantage of pot plants is seen, as they can be readily turned upon their sides and given a thorough syringing with an insecticide at weekly intervals.

BOUGAINVILLEAS. — Although many new climbers have from time to time been introduced, I think, for general decorative purposes, the bougainvilleas retain their reputation. Their free habit of growth has much to recommend them as roof climbers for the intermediate plant stove, or they may be found valuable for covering any unsightly back wall. The beautiful drooping floral sprays, where overhead space is available, will have a charming and graceful effect, and show up to better advantage than is possible when plants are trained upon a balloon-shaped trellis. When grown as standards they are also valuable, but it is advisable to train them into umbrella-shaped heads with from four to six feet of clear stem. Bougainvilleas are exceptionally strong-rooting subjects, and gross feeders, therefore they require a fair amount of root room, firm potting, and, as soon as the pots become filled with roots, they should receive liberal applications of some approved fertiliser, and an occasional watering with clear soot water. Plants may now be started into growth, and as soon as the buds have started they should be repotted. As a potting compost I recommend two parts of strong fibrous yellow loam, one of peat, and sufficient charcoal and coarse silver sand to keep the whole porous.

GENERAL REMARKS.—Extreme care must be exercised in watering newly-potted plants; frequent applications of water at this stage, when the roots are inactive, will make the soil sour, and disastrous results are sure to follow. Judicious and careful manipulation of the ventilators is most essential at this season, as the weather is subject to sudden changes. Avoid excessive heating of the hot-water pipes as the sun is becoming powerful, and if the pipes are overheated on a bright day much damage will be caused to the young and tender foliage of caladiums, alocasias, etc.—John Donoghue, Bardon Hill Gardens.

THE FLOWER GARDEN.

SWEET PEAS in pots, standing in cold frames, must be afforded abundant ventilation to promote sturdy growth. The lights should be removed to harden off the plants in readiness for putting out early in April. The growths will require supporting, and if grown singly one stake should be given to each plant; where several plants are raised in each pot a few twigs, with a piece of raffia passed round them, will keep the growths upright. I have never found it necessary to pinch the plants at this stage. They always make sufficient side shoots if allowed to grow naturally.

GLADIOLI should be planted without delay. They are very useful and showy, and highly appreciated for beds or borders. A bed of the old Brenchleyensis planted in conjunction with Anemone japonica alba is very effective, and the same variety goes well with Salvia patens or Calceolaria amplexicaulis. The Gandavensis, Childsi, and Nanceanus types are exceedingly beautiful, and so also is Lemoinei. The corms should be planted about four inches deep, a good loamy soil suiting them best. In the Southern counties they will pass through the winter unharmed if left in the ground, but the corms must be planted a little deeper than when they are lifted annually. Good-sized groups are most effective, and the ground may be carpeted with verbenas, violas, phloxes, or any other approved plants with a suitable habit of growth.

BEDDING PLANTS.—It will be necessary to remove bedding pelargoniums into cooler quarters, otherwise the plants will become weak and leggy. Unheated frames or houses are the most suitable places for them until they may be safely stood outside. If the pots are full of roots a little weak liquid manure may be given them occasionally. Repot any plants that require it, such as marguerites, heliotropes, specimen fuchsias, ivy-leaved geraniums, etc. Lobelias, alternantheras, iresines, and mesembryanthemums may still be propagated if necessary. All seedlings must be transplanted into boxes as soon as they are large enough to handle. These include antirrhinums, dianthus, nicotianas, nemesias, etc. The salvias, centaureas, carnations, Dimorphotheca aurantiaca, ricinus, etc., should be put singly into small pots.

SPRING BEDS.—The hyacinths, daffodils, tulips, and other bulbs likely to require support must be attended to before growth is too far advanced. The decaying leaves should be removed from wallflowers, polyanthus, etc., to give the beds a tidy appearance, and during dry weather the surface of the beds should be slightly stirred with a hoe.

LAWNS.—In many gardens the grass will soon require cutting, and it is important that the lawns are thoroughly swept and rolled beforehand, and the verges trimmed with the edging knife. It is rather late now for laying down fresh turf, but should there be any bare places remaining they may be renovated by sowing seeds, but some protection must be provided to prevent the birds from taking the seeds.—E. C. Pooley, Gnaton Gardens.

FRUITS UNDER GLASS.

MELONS.—The earliest plants are growing rapidly now, and require daily attention in the matter of tying. Put a bamboo stick in to each plant, and it is a good plan to tie another bamboo straight up the wires, as the growths can then be tied as often as required without any fear of breakage. Train up to the top without stopping for the cordon system. A little bone-meal may be given in small doses every week. Shut the house early, with sunshine, and syringe every part of the structure and plants thoroughly. Shift on successional plants as soon as they require it.

EARLY VINERY.—Keep the shoots from touching the glass, and stop when the best bunches can be seen. It is not wise to stop all the shoots at one time. The Black Hamburgh will now be coming into flower. Keep the house a little drier, and with a little air on; this will aid the setting. Examine the borders, and if necessary, give a thorough soaking; but if not dry, wait until the thinning has been done, then give a dressing of approved manure, water in, and apply a mulching.

MUSCATS.—A little heat may now be turned on these to enable the house to be kept at 50 deg. Examine the borders and see if they require water; give it at a temperature of about 60 degrees, but unless ample drainage is secured the chances are that the borders will not require much water at this period. Syringe the rods well at shutting-up time. Close at 2.15 p.m., give plenty of air on all fine days till growth commences, when, of course, the temperature must be kept up and less air given.

LATE GRAPES.—All vines may be started slowly now, as it is imperative that the crop should be reaching maturity by the end of September, therefore close the houses, but give air on all fine days, and maintain an even temperature without the aid of fire heat, except in frosty weather. In most cases it will be necessary to give a good watering to the inside borders, as these have been kept dry. Let the water be at a slightly increased temperature to that of the house.

CHERRIES.—These should be fumigated just before the blooming period. The cherry is very impatient of hard forcing; for this reason the growth must be slow, and this gives aphis a chance of getting a footing unless precautions are taken. A slight syringe with a nicotine preparation is also a good preventive.—W. A. Cook, Leonardslee Gardens.

PRELIMINARY NOTICE.

COUNTY BOROUGH OF STOKE-ON-TRENT.
HANLEY PARK.

THE FIFTEENTH
GREAT ANNUAL FLORAL FETE will take place in the HANLEY PARK on WEDNESDAY and THURSDAY, July 5th and 6th, 1911.

Schedules, which will be ready shortly, may be had on application to
WM. POULSON, Secretary.
Town Hall, Hanley.

THE PERPETUAL FLOWERING CARNATION SOCIETY.—The SPRING SHOW will be held May 2nd and 3rd, and the WINTER SHOW, Dec. 5th and 6th. Schedules and particulars from E. F. HAWES, Royal Botanic Gardens, Regent's Park, London, N.W. THE CARNATION YEAR BOOK, 1911, containing interesting articles, valuable information, and numerous illustrations, now ready, post free, 1s. 3d., from HAYWARD MATHIAS, Lucerne, Stubbington, Fareham, Hants.

THE BOURNEMOUTH HORTICULTURAL SOCIETY EXHIBITIONS.
SPRING FLOWERS, April 4th and 5th.
AUTUMN FLOWERS, etc., Oct. 31st and Nov. 1st, 1911.
C. W. BARRETT, Secretary, "Lucerne," Fenton Road, West Southbourne, Bournemouth.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

(Continued from page 202.)

Dewdrop, Incognita, Queen Sophia, Treasure Trove, White Witch, Topaz, Weardale Perfection, and Amazon, among other good things.

Mr. Frank Lilley, Guernsey, contributed a collection of forced daffodils, and included a considerable number of polyantha varieties in his set, and also a few spikes of Watsonia coccinea.

FRUIT AND VEGETABLE COMMITTEE.

Some capital vegetables from Messrs. Sutton and Sons, Reading, came in for a full share of admiration. Good things were Harbinger cabbage, Sutton rhubarb, seakale, Early Paris lettuce, Superb Early White broccoli, mushrooms, large-leaved dandelion, and Witloof chicory.

We understand that Mr. W. Poupart, Twickenham, exhibited a number of varieties of rhubarb all grown under similar conditions, to show their relative earliness, but we failed to find the exhibit.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Adiantum Glory of Moordrecht, from Mr. A. A. Fabius, Emsworth.

Award of Merit.—To Amaryllis Queen Mary, from Messrs. R. P. Ker and Sons, Liverpool; to Saxifraga Petrachi, from Sir Eric Hambro, Hayes Place, Kent; to Odontoglossum mirum braggense, from Messrs. Sander and Sons, St. Albans; to Tulip Yellow Murillo, from Mr. Profittlich, Twickenham; to Lælia-cattleya Dominiana var., from Messrs. Charlesworth and Co., Haywards Heath.

MEDALS.

Gold.—To Sir Eric Hambro, K.C.V.O. (gardener, Mr. J. Grandfield), Hayes Place, Kent, for alpines.

Silver-gilt Flora.—To Messrs. James Carter and Co., Raynes Park, for ornamental spring flower garden; to Messrs. Charlesworth and Co., Haywards Heath, for orchids; and to Mr. H. Burnett, Guernsey, for carnations.

Silver-gilt Banksian.—To Mr. H. Ellison, West Bromwich, for ferns and gerberas; to Messrs. Cartwright and Goodwin, Kidderminster, for daffodils; to Messrs. R. and G. Cuthbert, Southgate, for tulips.

Silver Flora.—To Mr. J. Box, Lindfield, for display of spring bulbs; to Messrs. William Paul and Son, Waltham Cross, for flowering shrubs; to Mr. G. Reuthe, Keston, for hardy plants; to Mr. L. R. Russell, Richmond, for flowering shrubs; to Messrs. Barr and Sons, Covent Garden, for daffodils; to Mr. Christopher Bourne, Simpson, for daffodils; to Messrs. J. Cypher and Sons, Cheltenham, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Mr. Collier, gardener to Sir J. Colman, Bart., Gatton Park, Reigate.

Silver Banksian.—To Messrs. J. R. Pearson and Sons, Lowdham, Notts, for daffodils; to Messrs. R. H. Bath, Ltd., Wisbech, for bulbs in moss fibre; to Mr. A. W. Jensen, Lindfield, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to Messrs. H. Cannell and Sons, Swanley, for pelargoniums; to Messrs. W. Cutbush and Son, Highgate, for carnations and hardy flowers; to Messrs. R. Gill and Sons, Falmouth, for rhododendrons; to Messrs. H. B. May and Sons, Edmonton, for ferns and azaleas; to Messrs. G. Mount and Sons, Canterbury, for roses; to Mr. Prichard, Christchurch, for hardy flowers; to Mr. Prime, gardener to the Marquis of Salisbury, Hatfield, for lachenalias; to Messrs. Sutton and Sons, Reading, for primulas—and one for vegetables; to Messrs. James Veitch and Sons, Chelsea, for flowering plants; to Messrs. T. S. Ware, Ltd., for hardy flowers.

Bronze Flora.—To the Misses Hopkins, Shepperton, for hardy flowers; to Messrs. R. Wallace and Co., Colchester, for alpine flowers; to Messrs. R. and G. Cuthbert, Southgate, for lachenalias; to Messrs. Paul and Son, Cheshunt, for lilacs; to Messrs. Robert Sydenham, Ltd., Birmingham, for daffodils.

FORCED BULB COMPETITION.

In some classes there was no competition, in some others it was excellent.

For eighteen hyacinths, distinct, Mr. E. Beckett was awarded first prize in a strong competition. The spikes were wonderfully developed, beautifully clean and fresh. The varieties were Koh-i-noor, Lord Derby, Schotel, Queen of the Pinks, Ivanhoe, Garibaldi, City of Haarlem, L'Innocence, Moreno, Electra, La Grandesse, La Victorie, Enchantress, King of the Blues, King Menelik, General Vetter. Mr. J. Gibson was second, having fine examples of Captain Boyton, Czar Peter, City of Haarlem, and Jacques. Mr. A. Hansom, Ivanhoe, Victoria Park, Wavertree, Liverpool, was a fair third; Mr. G. Dyke, gardener to Claude Watney, Esq., Garston Manor, Watford, was fourth. This was the largest class in the show.

For twelve varieties, distinct, there was a strong competition. Mr. H. Prime, however, came out first with a good even display. The varieties employed were Corregio, Koh-i-Noor, King of the Blues, La Grandesse, Ivanhoe, Jaques, Mr. Plimsoll, King Menelik, Schotel, City of Haarlem, Electra, and Le Victorie. Mr. J. W. Barker, gardener to F. R. Dixon Nuttall, Esq., Eccleston Park, Prescot, was a capital second, with clean, well-rounded spikes. Mr. J. Vert, gardener to Lord Howard de Walden, Saffron Walden, was third.

For six hyacinths, distinct, Mr. J. Shelton, gardener to Lord Hillingdon, Wildernesse, Sevenoaks, secured the first prize with really handsome spikes, just in the pink of condition. The second prize fell to Mr. H. Spittle, gardener to Mrs. H. Faudel-Phillips, Edenbridge, Kent; Mr. W. Howe was fourth.

For four pans of hyacinths, ten spikes each, Mr. E. Beckett obtained the first prize with splendid examples of King of the Blues, City of Haarlem, La Victorie, and Corregio; while an equal first was awarded Mr. James Gibson, for very fine pans. Mr. H. Prime, gardener to the Marquis of Salisbury, Hatfield, was a capital third, and Mr. G. Mackinlay, gardener to the Hon. J. Whitelaw Reid, Wrest Park, Ampthill, brought up the rear; there were six entries.

Messrs. R. and G. Cuthbert were the only competitors for 120 hyacinths in twelve pans, ten roots of each variety, and were again awarded a gold medal. The culture was simply superb, the varieties being Perle Brilliant, Jacques, Ivanhoe, Moreno, City of Haarlem, Corregio, L'Innocence, Schotel, La Victoire, Garibaldi, Chas. Dickens, and King of the Blues.

There were again three exhibitors for six hyacinths in moss fibre, Miss C. A. Michell, Oakfield, Cricklewood, gaining the first prize with a moderate exhibit. Mr. W. Howe was second with good close spikes, and Miss E. M. Rawlins, Great Houghton Hall, Northampton, was third.

The class for six vases of tulips, growing in fibre, only brought out three competitors, the first prize being awarded to Mr. W. Howe, gardener to Lady Tate, Park Hill, Streatham Common, who staged splendid vases of Duchess de Parma, La Reve, Queen of the Netherlands, Prince of Austria, Rose Grislin, and Joost Van Vondel. The Hon. Mrs. Guy Baring, St. Cross Mill, Winchester, was second with fine examples of Keiser's Kroon, Rose Grislin, and Fabiola, while Miss Gordon Thompson, The Elms, Potter's Bar, was awarded third prize.

The class for six vases of narcissi, grown in moss fibre, there were four entrants, Miss E. M. Rawlins securing first prize with nice bowls of White Lady, Emperor, C. J. Backhouse, Victoria, Leonie, and Madame de Graaf. Mr. W. Howe was a close second with fine examples of Victoria, Blood Orange, and Emperor. The Hon. Mrs. Guy Baring was third.

Messrs. R. and G. Cuthbert, Southgate, were the only competitors in the trade class for a collection of hyacinths in twenty-five varieties of four blooms each, and were deservedly awarded the gold medal of the General Bulb Growers' Society, Haarlem. The spikes were really fine and beautifully arranged in a bed of maidenhair ferns. The varieties employed were Captain Boyton, Mr. Plimsoll, Lord Balfour, La Grandesse, Charles Dickens, Perle Brilliant, King Alfred, L'Innocence, Ivanhoe, La Victoire, Rose de Merveille, Corregio, Lord Derby, King Menelik, Garibaldi, City of Haarlem, Pink Perfection, Electra, Queen of the Pinks, Jacques, General Vetter, Enchantress, Moreno, and Schotel.

Proposed National Daffodil Society.

The adjourned meeting to consider the question of instituting a National Daffodil Society was held at 2.30 p.m. on Tuesday, March 14, in No. 3 Committee Room at the Royal Horticultural Hall, Westminster. The Rev. G. H. Engleheart presided.

Mr. Cranfield pointed out that there was no need for a lengthy meeting, as that morning the R.H.S. Daffodil Committee had sent a resolution to the R.H.S. Council, asking: "That the Narcissus Committee be empowered to hold a two-days' show in mid April; to issue (through the council) a 'Year Book' annually; to issue a schedule of prizes (committee to find the cash prizes), and to divide itself into sub-committees for special purposes." He understood that the council had practically conceded all these requests, but the committee had not yet had an opportunity of acting. He thought it undesirable at present to move further in the matter of the National Daffodil Society, though he did not propose to abandon the idea of such a society until he and his friends saw how the Narcissus Committee would work under the new conditions. He did not think it would work successfully, but he did not wish to do anything that would hamper their movements, and, therefore, he moved the postponement of the question of a National Society until, at any rate, the Narcissus Committee had had an opportunity of meeting the wants and desires of so many daffodil lovers.

Mr. H. A. Darlington, Mr. F. H. Chapman, the Rev. J. Jacobs, Mr. Welchmann, Captain Parlby, and others spoke, some of them throwing blame upon the Narcissus Committee for not having moved in the matter of popularising daffodils long ago. The Chairman pointed out that such blame was unfair, because the committee was constituted for a specific purpose, and had no powers outside that purpose, until these were given to meet any demand arising from the Fellows of the society. In this particular the chairman appeared to be well supported.

Mr. Cranfield's motion of postponement was put, and carried, and very cordial votes of thanks were accorded him for his keen interest and work in connection with the present movement, and to the Rev. G. H. Engleheart for presiding. The next move is with the Narcissus Committee.

There was an excellent attendance on this occasion, representatives coming from Cornwall, Devon, Somerset, Huntingdon, Birmingham, and other daffodil centres, as well as from the Metropolitan district, while most of the members of the R.H.S. Narcissus Committee were also present.

Scottish Horticultural Association.

The March meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 7th. Mr. Massie, the president, occupied the chair, and there were 150 members present.

Mr. Wm. Cuthbertson, J.P., of Messrs. Dobbie and Co., Edinburgh, delivered a lecture on "Sweet Peas." Prior to 1901, he said, there was no "Spencer" or waved sweet pea. Previous to that time there were two types—one with erect standards, represented by "Triumph" and "Prince Edward of York," and the other with hooded standards, represented by "Lady Grizel Hamilton," and these still appeal to some florists, to whom the "Spencer" forms are anathema, just as the fancy pansies were anathema to the lovers of the old show pansy. At the annual exhibition of the National Sweet Pea Society at the Royal Aquarium, London, in July, 1901, Mr. Silas Cole, gardener to Earl Spencer, at Althorp Park, Northampton, showed a new sweet pea which he named Countess Spencer, and this was awarded a first-class certificate. This variety made possible the modern development of the sweet pea, and it may be of interest to give the narrative which Mr. Cole conveyed to Mr. Cuthbertson as to how it came into existence. "With respect to the origin of Countess Spencer," he wrote, "I will tell you what happened. Being always very fond of sweet peas, I turned my attention specially to them in 1898. That summer I crossed Lovely with Triumph, saved the seed, and the following year, 1899, there were two or three promising things, the rest being rubbish. The good ones I crossed with Prima Donna, and the next season, that was 1900, there was one plant among the seedlings much stronger than any of the others, and flowered much later than the other varieties. That proved to be the original 'Countess Spencer.' I just managed to save five seeds—one pod only. The following spring, after sowing them, I lost three of them in one night, with mice. The stock was thus reduced to two plants, but from these I saved 90 seeds. It was from these plants I exhibited the flowers at the Royal Aquarium for the first time. In 1902 I sowed all the seeds. Every one came true, but owing to it being a wet summer I only managed to save about 3,000 seeds; 2,200 of these were sent in 1903 to America to be grown for stock by Mr. Sydenham. What came back from America was a mixture of all sorts, no more like my true Countess Spencer than day is like night. With me Countess Spencer has never sported to this day. It has thrown reversions, that is, it has reverted back to its parents, Lovely and Triumph, and on rare occasions to Prima Donna, but nothing else. To my mind that is not sporting. That is all there is to tell about the origin of Countess Spencer."

Mr. Cuthbertson gave a brief account of the sweet peas which had been awarded medals and certificates by the National Sweet Pea Society, and then dealt with the purity and fixity of stocks. Last year over 300 trials had been made at Guildford, but only 129 of them had proved true. There were two ways of obtaining new varieties. One was by selecting and fixing a variation, of which "Helen Lewis" was an example, and the other was by cross-fertilising and selecting from the progeny. In the latter the characters of the parents are commingled, but no reliance, as we now know, thanks to Mendel's discoveries, can be placed on the plants of the first generation. They are only unfixed character carriers, and Mr. Cuthbertson gave the following illustration: If Countess Spencer be crossed with King Edward, the progeny are all reds of the King Edward type. Seed saved from these plants, when selfed, will produce many plants of the King Edward type, red and pink in colour, a few true Countess Spencers, and very few of the Spencer type, but red in colour. The last will produce in the next generation some variations, and those which remain true must be bred again, until the stock is homozygous, or breeds true to the desired character. Mr. Cuthbertson strongly deprecated the placing on the market of novelties which were not properly fixed.

On the motion of Mr. Hay, Mr. Cuthbertson received a very cordial vote of thanks for his interesting lecture.

The exhibits were: Twenty-three varieties of wallflower, from Messrs. Dobbie and Co., Edinburgh; hybrid primulas (P. obconica x P. stellata), Galanthus Elwesii, Sisyrinchium grandiflorum, and Helleborus niger major, H. orientalis abschasicus, H. orientalis abschasicus multiflorus grandiflorus, and H. orientalis purpurascens major, from Mr. C. Comfort, Broomfield, Davidson's Mains; flowers of Rhododendron Nobleanum hybrids from Mr. A. Johnstone, Hay Lodge, Edinburgh; Richardia æthiopica, from Miss Burton, Poulton; Dendrobium Nobleanum, from Mr. R. Whannell, The Drum, Gilmerton; spring flowers from Mrs. Algie, Togher House, Co. Mayo; and Brussels Sprout Solidity, from Mr. I. Staward, St. Fort, Newport, Fife.

Eleven new members were elected.

The next monthly meeting, on April 4, will be for the young members, who are asked to read short papers on horticultural or allied subjects.

United Horticultural Benefit and Provident Society.

The annual meeting of this flourishing benefit society was held in the Horticultural Hall, Westminster, on Monday evening, March 13. Mr. Chas. H. Curtis presided. Besides the committee and officers there were very few members present, the small attendance being probably accounted for by the very inclement weather of the afternoon and evening.

The usual formalities were observed, and then, at the suggestion of the Chairman, the report and balance-sheet for the year 1910 were taken as read. We regret that the pressure upon our space prevents us from giving the report in extenso, but possibly we may have an opportunity of giving it in a succeeding issue. In moving the adoption of the report, the Chairman reviewed the chief items of interest, and pointed out that the present number of benefit members was 1,366, including the addition of 70 members during the year. Sick pay for the year was £561 0s. 6d., or £9 less than in the previous year. The management expenses came to £229 9s. 7d., and included the extra expenditure of £21 incurred by the quinquennial actuarial valuation of the society. The Chairman pointed out that £3,000 worth of stock had been purchased in 1910, the largest amount invested in any one year, and now the society's invested capital amounted to £38,800, in addition to £200 on deposit, and a sum of £200 on current account. He paid a tribute to the continuous and excellent work of the committee, the admirable manner in which Mr. Collins fulfilled the duties of secretary, the business capabilities of Mr. W. P. Thomson, the treasurer, and the keenness of the trustees in securing the best possible investments. He also pointed out that while the £38,800 worth of stock held had a present market value of £35,200, yet all was redeemable at par, and was practically all of it purchased considerably below par, and, moreover, there was a surplus fund of £2,623 16s. 2d. to provide for depreciation. Mr. Kendal seconded the motion, and said he thought it would be a gracious act on the part of the private members if they came to the annual meeting in larger numbers to show their appreciation of the committee's services. The motion was then put, and carried.

Messrs. E. Burge, A. Bedford, T. Stanbridge, and W. Weston, the four retiring members of the committee, were re-elected on the motion of Messrs. Kendal and Winter, the former suggesting that the out-of-pocket expenses of committeemen ought to be paid by the society. On the motion of the Chairman, seconded by Mr. J. Wheeler, Mr. W. Collins was heartily re-elected as secretary, and many kindly things said of his work. Messrs. Gunner and Puzy were re-elected auditors, the former for the 23rd successive year. The trustees, Messrs. J. Hudson, Riley Scott, and C. H. Curtis, were heartily thanked for their services, and Mr. W. P. Thomson was also accorded a hearty vote as treasurer. The Press was accorded hearty thanks for many kindnesses to the society, and Mr. J. Harrison Dick acknowledged the vote. A similar vote to the committee was moved by Mr. Collyer and Mr. Kendal, and acknowledged by Mr. A. Bedford. It was suggested by Mr. Collyer that if, in addition to the notices in the Press and in the Annual Report, members could be individually notified of the annual meeting, possibly more would come.

The death of Mr. Chas. Foster, and also of Mr. George, one of the oldest members, were referred to, and votes of condolence and sympathy sent to the bereaved families.

A vote of thanks to the chairman, moved by Mr. Hawes and Mr. Winter, concluded the proceedings.

At a subsequent committee meeting Mr. Chas. H. Curtis and Mr. T. Winter, were again heartily re-elected as chairman and vice-chairman, respectively, of the committee.

Reading Gardeners' Association.

At the fortnightly meeting of this association, held on Monday, March 6, the vice-president, Mr. Leonard Sutton, occupied the chair, and, nothwithstanding the unfavourable weather, there was a good attendance.

The lecturer for the evening was Mr. W. F. Giles, of Messrs. Sutton and Sons, and his subject, "British and Continental Salads." Mr. Giles has made a special study of the culture of saladings, and his lecture, most carefully prepared, was illustrated by an exceedingly interesting collection of lantern slides, many of them from photographs taken by himself in Great Britain and on the Continent. Mr. Giles gave a brief description of practically all the plants used as salads, first dealing with those which may be said to be well known in this country, such as lettuces, endive, radishes, mustard, cress, celery, young onions, cucumbers, tomatoes, etc. Afterwards he described those not so well known to the English cultivator, but which are in constant use in Holland, France, Italy, and other Continental countries.

He expressed the opinion that the increased demand for saladings in our own country was doubtless greatly due to the large number of Britishers who now visit the Continent acquiring the taste for salads as served in Continental hotels and restaurants. Mr. Giles was, however, confident that although the gardeners across the Channel might be a little ahead of us in the production of seasonable salads the British gardener easily led the way in the culture of vegetables generally, as evinced by a comparison between English and Continental exhibitions. The French, or intensive system of cultivation was described in detail, and pictures were thrown on the screen illustrating the methods adopted in some of the largest gardens of Holland, Belgium, and France, as well as of establishments in our own country.

The following is a list of the leading Continental types of saladings, and each was in turn fully described, the method of cultivation being also explained: Chicory, witloof, dandelion, finnochic or Florence fennel, mache or corn salad, rampion, celeriac, purslane, tarragon, chervil, pimpinella, sorrel, chives, mercury, orache, poiree, and winter radishes.

Mr. Giles then dealt with the mode of procedure adopted in the preparation of salads by Continental experts, explaining that the knife for shredding is never used as in this country, lettuce leaves being torn from the plants, the most scrupulous care being also taken that nothing goes into the salad bowl in the slightest degree wet. Oil and vinegar are used as ingredients for flavouring, but the latter only in sufficient quantity to give an appetising relish.

At the conclusion of his remarks Mr. Giles was warmly applauded, and, on the proposition of the vice-president, seconded by Mr. Powell, a hearty vote of thanks was accorded him.

A very beautiful exhibit of Primula obconica was staged by the chairman of committee, Mr. F. Townsend, gardener to Leonard Sutton, Esq., Hillside, Reading.

Birmingham Gardeners' Association.

MARCH 6.

Once again Mr. E. H. Jenkins, of Hampton Hill, Middlesex, essayed to entertain the members of this society, and on March 6 gave a dissertation upon one of his favourite subjects, viz., "Alpine Plants." Mr. C. H. Herbert presided over a large assembly.

In his prefatory remarks Mr. Jenkins intimated that he did not purpose offering practical advice on the ordinary culture of alpines, nor give a catalogue of species and varieties; but to discuss the principles appertaining to the natural habitats of the highly interesting plants, the study of which, beside being interesting, would prove of material assistance to the cultivator. In the course of his remarks, the essayist adverted to the astonishing depths that the roots of even some of the most diminutive species of the plants attain in search of moisture between the fissures of the rocks, whilst their foliage and flowers were luxuriating in the pure, clarified, and cold mountain air above. Wonderful, too, is their power of acclimatisation, ranging from the lofty Alps to the temperate regions.

Naturally, also, advertence was made to a few of the more popular kinds and species of both the "Incrusted" and the "Mossy" sections of saxifrages. Here it will be opportune to remark that Mr. Jenkins drew attention to the small collection of saxifragas brought to the meeting by the chairman, from Acock's Green, especially resplendent being a very fine clump of S. oppositifolia major, which Mr. Jenkins declared was the finest he had ever seen. Another notable specimen being S. apiculata alba. The exposition was listened to with close attention, and Mr. Jenkins encouragingly invited a discussion and questions when expressing thanks for the attention devoted to his necessarily cursory details on so large a subject.

Chief amongst the few discussionists was Mr. James Webb, gardener to Byng Kenrick, Esq., Metchley House, Edgbaston, and who gave a long descriptive list of the saxifrages and other alpines flourishing there in proximity to a smoky region. Mr. Foster, of Acock's Green, when referring to his own comparatively small experience amongst the alpines in Switzerland, remarked that it afforded him very much gratification to be in the presence of Mr. Jenkins that evening for the first time, though during upwards of thirty years he had acquaintance with the latter's contributions to the horticultural Press.

A hearty vote of thanks, proposed by Mr. W. Spinks, and seconded by Mr. A. R. Brown, to Mr. Jenkins, was carried with acclamation.

Dundee Horticultural Association.

The usual monthly meeting was held in the Technical College, on the evening of the 9th inst. The president, Mr. William Christison, presided over a good turnout of members. Mr. Alexander Macrea, assistant superintendent of parks and cemeteries, was the lecturer, and his subject was "Ground Operations." Dealing with this subject in a masterful way, the lecturer lucidly explained the best recognised methods of levelling, trenching, draining, making walks and carriage ways, bowling greens, croquet lawns, and tennis courts, greatly enhancing his remarks by means of diagrams and sketches on the blackboard. The lecture evoked considerable discussion, and the lecturer was plied with a multitude of questions, which he answered to everyone's satisfaction.

In voicing the thanks of the members to Mr. Macrea, Mr. James Bethel said he was surprised to note from the discussion that took place that so many of the speakers thought the operations which the lecturer had so eloquently dealt with were not a part of their work. Apart from the question of remuneration, which had been ventilated by one speaker, his idea was that the average gardener should equip himself with all the general knowledge he could command. Knowledge was power, and it was not to the credit of the present-day gardener if he was unable to successfully perform the work which Mr. Macrea had so ably dealt with.

The exhibits consisted of carnation stems showing aerial roots, from Mr. Thomas Butchort, Rosemount Gardens, Newport; and a bunch of Himalayan rhododendron flowers from Mr. John Campbell, Foggyley Gardens, Lochee.

Eckford's
Giant SWEET PEAS

THE FINEST BLOOMS IN THE WORLD.

A flower garden without Eckford's Sweet Peas can only be compared to a house without furniture. Sweet Peas are requisite to the small, medium, or large garden, and if you wish to have colour, effect, prize specimens, and tall plants, then send to Eckford's for your seeds. The time to buy is NOW. The firm to buy from is ECKFORD'S. No other seed specialist in the world can rival Eckford's for Sweet Peas. Larger flower, longer stems, brighter colours, and a profusion of bloom will be the result of growing Eckford's seeds.

REMEMBER GENUINE ECKFORD'S SEEDS CAN ONLY BE OBTAINED DIRECT FROM WEM. No Agents are employed.

Over 150 Gold and Silver Medals have been Awarded for Eckford's Seeds.

SPECIAL COLLECTIONS for 1911.

Exhibitor's (E) Collection. 24 Giant Waved varieties, new and up-to-date; fine for exhibition, 10 seeds of each, for **5s. 6d.**, post free, cash with order.	**Villa (B) Collection.** 24 splendid varieties, suitable for exhibition, 50 seeds of each, **5s. 6d.**, post free, cash with order.	**Exhibitor's (D) Collection.** 12 Giant Waved varieties, new and up-to-date; fine for exhibition, 10 seeds of each for **2s. 9d.**, post free, cash with order.
Villa (C) Collection. 12 splendid varieties, suitable for exhibition, 50 seeds of each, **2s. 9d.**, post free, cash with order.	**Half Villa (F) Collection.** 24 splendid varieties, suitable for exhibition, 25 seeds of each, **3s.**, post free, cash with order.	**Villa (E) Collection.** 12 splendid varieties, suitable for exhibition, 25 seeds of each, **1s. 6d.**, post free, cash with order.

ECKFORD'S "CORONATION" MIXTURE OF GIANT SWEET PEAS—Red, White, and Blue. This is a mixture specially provided for the Coronation Year, when quantities of flowers of these colours will be needed for all manner of decorations. It consists of equal quantities of fine red, white, and blue Sweet Peas. Per lb., **5s.**; 8oz., **2s. 6d.**; 4oz., **1s. 6d.**; per oz., **7d.** These mixtures are not to be equalled in their respective grades, and are only obtainable direct from Wem. The colours in these mixtures are so carefully blended that they give the most universal satisfaction. Testimony is continually coming to hand which speaks in high praise of their excellence.
A specially written booklet on Sweet Pea Growing given with every order. Send to WEM for satisfaction.

ECKFORD'S IDEAL FLOWER GARDEN SEEDS.

I have great pleasure in placing before gardeners my special collections of Garden Seeds, which I am confident will give the utmost satisfaction. All seeds are carefully selected under my own supervision, and can be relied up to produce an abundance of choice blooms.

ECKFORD'S 5s. IDEAL COLLECTION.

1oz. Eckford's "Matchless" Mixture of Giant Sweet Peas; 3 packets of choice Asters, separate colours; 3 packets of choice Double Ten-week Stocks separate colours; 3 packets of Ornamental Grasses for mixing with cut flowers; 1 packet of each of the following **twelve** Hardy Annuals: Alyssum for edging, Calliopsis, Shirley Poppy, Annual Chrysanthemum, Schizanthus, Eschscholtzia, Godetia, Miniature Sunflower, Larkspur, Mignonette, Nasturtium, and Nigella; 1 packet of each of Half-hardy Annuals as follows: Lobelia, Nicotiana, Marigold, and three Everlastings for Winter Decoration; 1 packet each of Hardy Perennials, as follows: Antirrhinum, Aquilegia, and Canterbury Bells; with one packet of Single Wallflowers.

5s. post free for Cash with order.

FREE. Send a postcard to-day for large illustrated and coloured Catalogue. It gives full particulars of all novelties in Sweet Peas for 1911, and contains full list of all flower and vegetable Seeds.

HENRY ECKFORD, F.RH.S., Sweet Pea Specialist,
(Dept. 221), **WEM, SHROPSHIRE.**

Lee, Blackheath, and Lewisham Horticultural Society.

At the Church Street Schools a lecture was recently given by Mr. G. E. Dibley, F.G.S., on "The Fertilisation of Flowering and So-called Non-flowering Plants."

Mr. Dibley dealt with his subject in a very able manner, illustrating his lecture by means of an excellent series of lantern slides. Starting with the angiosperms, he traced the line of evolution through various groups of plants until he came to the primitive algæ, from which the more highly-developed trees, shrubs, and plants so familiar to us have been gradually evolved. The lecturer divided the angiosperms into the two classes, monocotyledons and dicotyledons; these he then divided up into the various sub-classes, e.g., the dicotyledons into Thalamifloræ, Calyciifloræ, Gamopetalæ, and Incompletæ, and the monocotyledons into the sub-classes Spadicifloræ, Petaloidæ, and Glumiferæ, giving the different characteristics of the various groups, and their mode of pollination, fertilisation, development, and dispersal of fruit or seed.

The gymnosperms next claimed his attention, and, after describing the method of fertilisation, the position of the naked ovules on the cone of pinus, and the long time required for fertilisation to be completed, after pollination had taken place, he passed on to the selaginellas, showing to the audience, by means of specimens, the position of the microspores and macrospores on the tip of the leafy stem.

He next gave the life history of a fern, explaining clearly the two different phases in its life cycle. After this he dealt with the club mosses and liverworts, and these came in for a long discourse, as here was vegetative as well as sexual reproduction to describe. The lecturer then passed on to the Algæ, giving, for examples, the Bladderwrack (Fucus vesiculosus) and Spirogyra, describing how the latter was reproduced by the conjugation of two unicellular plants. He also gave a brief account of a fungus (agaricus) and its method of reproduction by spores, passing on from agaricus to the lichens, and explaining the symbiotic relationship which exists between the fungi and algæ, which go to make up the lichens.

At the close of the lecture Mr. Dibley was accorded a hearty vote of thanks. On March 31, Mr. G. B. Lees, will give a lecture on "Outdoor Roses."

Bournemouth Gardeners' Association.

On March 7, Mr. Bowder, of the Victoria League, gave a most instructive and interesting lecture on the "Different Ways of Farming from East to West, including the Culture of Fruit and Vegetables in Canada." The president (J. H. Ralph Smythe, Esq., J.P.) presided, and introduced the lecturer to an audience of nearly one hundred persons.

The lecture was illustrated by eighty lantern slides, and greatly appreciated. Mr. Bowder dealt chiefly with fruit growing in New Brunswick. He said the cultivation of fruit had been brought to a fine art in British Columbia. He stated that there were 14,000,000 acres suitable for the cultivation of fruit, chiefly apples, and that New Brunswick was just coming to the front. Experts declared that it was the finest part for fruit growing. Apples grown in New Brunswick matured quite fourteen days earlier than they did in Novia Scotia, and thus brought the cultivators a good return for their outlay. One pioneer grew eighty different varieties of apples, and although it was not good policy to have so many, the fact proved that a great variety of apples did remarkably well in the province. Small bush fruits and strawberries did very well between the rows of fruit trees, and a profit of from sixty to one hundred pounds per acre could be realised from strawberry culture. Cabbages and tomatoes also did extremely well in the flat districts. The lecturer said he had never seen finer tomatoes grown under glass in this country than he had in the open air in New Brunswick. Nearly every farmer had fruit orchards attached to his farmstead.

Mr. Bowder said there were "illustration orchards," ranging in size from one to two acres, which were of great value to the fruit growers. These orchards were maintained by the Government for ten years, and the fruit belonged to the owner. The Government replaced trees that died during that period. The lecturer laid much stress on the desirability of spraying fruit trees at stated times during the season. Without this precaution, he said, fine crops of fruit could not be obtained. He said experiments had been made by spraying one side of a tree only, and leaving the other side unsprayed, and the result was most marked in favour of spraying. The machine for the purpose was placed in a cart. A long tube from the machine was attached to a bamboo cane about 10ft. long, and this enabled the operator to get at all parts of the tree with ease and facility. Sweet corn, the lecturer said, was largely grown, and much liked in a cooked state.

Mr. Tompkins, gardener to the Dowager Lady Miller, staged some splendid primulas in pots and violets in vases, and Mr. Heath had a beautifully-flowered white azalea and a large fern. Votes of thanks were heartily accorded both the lecturer and chairman at the close of the meeting.

Elstree and Boreham Wood Horticultural Society.

Mr. E. Beckett, V.M.H., gave an interesting lecture on "Vegetables" on Friday, the 3rd inst., in connection with the above society, at Letchmore Heath. There was a large audience. The lecturer, in his opening remarks, referred to the initial work in connection with vegetable growing that must be done to ensure the best success. He spoke on the selection of a site, cultivation of the ground, manuring, etc., and afterwards took the more important vegetables individually, and touched on the more salient points in their culture. A splendid series of lantern slides added considerable interest to the lecture, and showed the best types of vegetables, as well as many of the collections that have been exhibited throughout the country. J. R. Paul, Esq., was the chairman. A vote of thanks was accorded the lecturer and the chairman.

OBITUARY.

MR. ROBERT MACKENZIE CROSS.

The death is announced at the age of 76 of Mr. R. M. Cross, who in the course of his long and active life, rendered valuable assistance in the introduction of cinchona and rubber plants into India. A native of Dumbarton, Mr. Cross commenced his gardening career in the gardens of Sir James Colquhoun, Bart., of Luss, and subsequently coming to London, he was, on the recommendation of Mr. J. Smith, the Curator at Kew, appointed to make a journey to Ecuador in quest of the red-barked cinchona, in order to establish it in the Neilgherries of Madras, and in this he was successful, and established 500 plants. Later he went, also for the India Government, to Loxa to collect seeds of the Crown Bark (Cinchona officinalis), and in this enterprise also he achieved much success, 80,000 plants having been raised from the seeds he collected. He made five other visits to South America, and collected large quantities of seed of other cinchonas, and of several rubber plants, notably Castilloa elastica, and Hevea brasiliensis.

MR. JAMES GEORGE.

As we are going to press we learn that Mr. J. George died a few days since at his residence at Putney, in his eighty-fifth year. We shall give a short account of the life of this veteran horticulturist in our next issue.

ANSWERS TO CORRESPONDENTS.

WINTER-FLOWERING SWEET PEAS.—M. C. A., Leatherhead: It is quite impossible for you to obtain flowers of the winter-flowering sweet peas during January in houses entirely unheated. It may be possible in South Devon or Cornwall to do so, but we much doubt it.

PLANTING ASPARAGUS BEDS.—S. H., Leicester: For the beds you have made, i.e., those four feet wide, three rows of plants will be necessary, and the plants should be set out fifteen inches apart in the rows. It is an advantage if dull, damp weather can be chosen for the work of planting. The end of March and early April afford the best period in which to plant new beds, and it is always a distinct advantage if good two-year-old plants are obtained. Every care must be taken to prevent undue exposure of the roots, and the more quickly planting is done after lifting, the better. Connover's Colossal is a first-rate variety in every respect, and there is no need to grow any other.

SOWING NEMESIAS.—R. P. S., Exeter: The trouble is probably due to the fact that the seed boxes were placed in considerable heat. The nemesias are half-hardy annuals, but they very much resent artificial heat. The seeds rarely germinate well when sown and placed in moderate stove heat, whereas if sown from now onwards and placed in a cool house or frame they will germinate freely; indeed, if sown out of doors towards the end of April, in a shady position, they germinate quickly and well.

SULPHUR FUNGICIDE.—W. L. C., Chester: No doubt you refer to liver of sulphur, also known as sulphide of potassium. An excellent fungicide is made by dissolving an ounce of the sulphide in a pint or two of hot water, and then adding cold or tepid water sufficient to make up 2½ gallons of mixture.

ICICLE RADISH.—H. J. B., Stroud: This is a capital radish, and one that possesses several virtues. It is very crisp and succulent, of good flavour, and does not deteriorate or run to seed so quickly as many varieties do. For a radish it is rather large, but this is not necessarily a defect. We grew it last summer in a small trial of numerous varieties, and found it very good and useful.

DOUBLE-SPATHED ARUM.—W. P., Bideford: We invariably receive a number of arum freaks during the season, and yours is the first to reach us in 1911. You will have noticed that the lower spathe is not so circular as the upper and true one, and also that it is tinted with green. A spathe is but a modified leaf, and the secondary spathe in your case is the result of an effort on the part of the sheathing leaf to become a spathe. On the whole, it has succeeded very well, but it is not very likely the plant will make the attempt another year.

HOLLAND HOUSE SHOW.—J. J., Selby: There will be no exhibition at Holland House, Kensington, this year, but instead, there will be a very large show at Olympia, close to Addison Road Station, and only a few minutes' walk from where the Holland House Show has been held. The dates of the Olympia Show are Tuesday, Wednesday and Thursday, July 4, 5, and 6.

DISEASED SWEET WILLIAMS.—H. S., Blackwater: The sweet williams are suffering from a very bad attack of a rust fungus, Puccinia arenariæ. This pest attacks numerous weeds and common plants, such as Stellaria media, S. uliginosa, S. Holostea, Sagina nodosa, S. procumbens, Spergula arvensis, and Arenaria trinervia, hence it is very desirable that these, and similar plants likely to be attacked, should not be allowed in the garden. A cure for the disease is practically impossible, but the removal and burning of badly affected leafage, and spraying the plants at intervals with a rose-red solution of permanganate of potassium will probably hold the disease in check, and prevent an increase of the trouble.

THE LANGUAGE OF FLOWERS
"Feed us, we pray you, with
CLAY'S FERTILIZER
and our rare beauty and fragrance will repay you."

A List of Gardeners on the Register will be supplied to employers only upon application to the Publishers if a stamped envelope is forwarded, addressed 148 and 149, Aldersgate Street, London, E.C.

Situations Wanted.

GARDENER (Head, where several are kept); thoroughly experienced in all branches, Inside and Out; grapes, peaches, melons, stove and greenhouse plants; four and a-half and eleven years' excellent references as head; married, family out. E. STONE, 13, Coniston Road, Addiscombe, Croydon, Surrey.

GARDENER (Head): general all-round knowledge; life experience in large and well-kept establishments; 13 years Head in last situation; age 39; married; gentleman will recommend. T. HARRIS, 2, Mill Lane, Cheshunt, Herts.

GARDENER (Head): good Single or Fruit Gardens Manager; Budder, Grafter, Pruner, Cucumbers, Melons, Vines, Chrys., Bedding Plants, Roses, Mushrooms, ridge or flat; Kitchen, Lawn, Flower Garden. Special Prize 1910. W. BLOOMFIELD, Staplehurst, Kent.

GARDENER (Head, where three or more kept), strongly recommended; excellent references, 24 years' most thorough experience every department; 12 years Head; age 40 years; married; abstainer. HORTUS, 135, London Road, Brighton.

GARDENER (Head Working, where three or four are kept); thoroughly experienced in all branches, Inside and out; also land and stock if required; age 38; married, no family; disengaged. HARE, Lynton, Bisley, Woking.

GARDENER (Head Working, where two or more are kept); good all round; can be well recommended; married when suited; age 36. PEARCE, 10, Roxwell Road, Shepherd's Bush.

GARDENER (Head Working), requires SITUATION; experienced in Vines, Peaches, Melons, Cucumbers, Stove and Greenhouse Plants; Flower and Kitchen Garden, Hardy Fruit, etc.; good references, married, no family. W. S., 73, Allen Street, Maidstone, Kent.

GARDENER (Head Working), married, no family; age 36, life experience in all branches, Inside and Out; excellent references; Wife dairy, or house, if required. A., 27, Effingham Road, Reigate, Surrey.

GARDENER (Head Working).—Gentleman strongly recommends his foreman, who has been with him for 5½ years; thoroughly understands the cultivation of first-class fruits, flowers, and vegetables, and the general routine of a well-kept garden; married; age 32. STEVENS, The Lodge, Boston House, Brentford, W.

GARDENER (Head Working).—H. ESSAM can with confidence recommend his Foreman, where several are kept; life experience in all branches, age 30; married when suited; excellent references. Address Closes Hall, Gisburn, Clitheroe.

GARDENER (Head Working).—Mr. WATSON can highly recommend C. WALLIS, where two or three are kept; been here six years as Second of five, age 30, married, one child. The Gardens, Bushey Down, Tooting Common.

GARDENER (Head Working); late with W. H. Herbert, Esq., Coventry, previously Mill House, Halifax; Vines, Peaches (speciality), Early and Late Forcing, Stove, Greenhouse Plants, Herbaceous, Rock Plants, Roses, Flower, Kitchen Garden, general upkeep Land, stock; 18 years Head, references unimpeachable. LOWE, Wylde Green, Birmingham.

GARDENER (Head Working); life experience in all branches; excellent references from present and past employer; age 27; married when suited. L. BARKER, The Gardens, Manor House, Alton, Hants.

GARDENER (Head Working). Mr. F. BERRILL, of Hall Close, Kettering, wishes to recommend FRANK DAINTY, who is a thoroughly capable Gardener, with life experience Inside and Out; 8 years in present situation; age 36; married, no children. DAINTY, Hall Close, Kettering.

GARDENER (Head Working, where two or more kept); married; age 33; life experience, Inside and Out; 4 years' present situation as Outside Foreman; well recommended by past and present employer. A. BACON, The Gardens, Rickmansworth Park, Herts.

GARDENER (Head Working, where three or more are kept). Mr. LAST, The Gardens, Homewood, Chislehurst, Kent, can with every confidence recommend his Foreman, W. WAITE, as above; 13 years' experience, gained in good establishments; five years present situation. Married when suited.

GARDENER (Head or Single-handed); age 30; married; life experience, Inside and Out; excellent character; well recommended. S. GANDY, Ponders Lodge, Margaretting, Essex.

HUGH LEWIS, Esq., wishes to highly recommend his GARDENER (Head); many years' experience in all branches; expert in Hardy and Alpine Plants and all forms of Gardening on natural lines; married, one child. Apply to W. INGWERSEN, Mayfield, Harewood Road, South Croydon.

LADY LUARD strongly recommends C. RUSHEN as Head Gardener, where two or three are kept; life experience; glass and all other branches; most hard working; leaves through break up of establishment. Write LADY LUARD, Witham, Essex.

MAJOR HOLROYD, Ropley Manor, Alresford, Hants, wishes to highly recommend his late HEAD GARDENER; 18 years' practical experience in all branches of gardening Inside and Out; Single; age 32; excellent references. SCREEN, Coombe Hill Gardens, Butlers Cross, Tring, Bucks.

GARDENER (good Single-handed or otherwise); life experience; good all-round Man in all branches; age 45; married, one child; would take very moderate wage with cottage for a comfortable place. Excellent testimonials; willing to be useful. F. OSBORNE, 48, Bradshaw Road, Watford.

GARDENER (Single-handed or where two are kept); good all round experience; Inside and Out; highly recommended; age 24. T. JACKSON, Rush Court Gardens, Wallingford, Berks.

GARDENER (Single-handed or otherwise); Glass, Kitchen Garden, and Pleasure Grounds, etc.; willing to make himself useful; good references, single. MILLER, 208, Park Road, Crouch End, London, N.

GARDENER (Single-handed or with help); life experience, good grower and propagator, Inside and Out, age 38; married, good character. ANDREWS, 28, Rookstone Road, Tooting, S.W.

GARDENER (Single-handed or Second), good practical experience Inside and Out, highly recommended, age 26, married when suited. G. OLIVER, 17, Gravel Road, Bromley Common, Kent.

GARDENER (Single-handed); little or no glass; 10 years experience in present place; single; age 28. W. REEKS, 89, Amwell Street, Hoddesdon, Herts.

FOREMAN or good JOURNEYMAN (Inside); 11 years' experience Chrysanthemums, Carnations, Fruit, Plant Houses; 3 years present situation; age 27; well recommended. DEAN, The Gardens, Grantlands, Uffculme.

FOREMAN (Inside), age 26; married, one child; 12 years' experience; good references; well recommended; 4 years here. H. W. PEARSON, Sandling Park, Hythe, Kent. (No circulars.)

GARDENER (Second, or good Journeyman), Inside; 11 years' experience in all branches; age 25; abstainer. E. JONES, Oakdene Gardens, Holmwood, near Dorking, Surrey.

MR. PERKINS, Gardener to late Mr. Rydon, Prylands, Highbury New Park, can recommend J. ANTHONY as Second of three or four. London Colney, St. Albans, Herts.

JOURNEYMAN (First). F. WILES highly recommends H. BANE as above, or as Journeyman (Second) in very large establishment; age 26; 11 years' experience in Plant and Fruit Houses. Middleton Hall Gardens, King's Lynn.

JOURNEYMAN (First, Inside) in good establishment; age 24; eight years' experience; good references; can be well recommended. T. BLIGH, The Barton, Helland, Bodmin, Cornwall.

JOURNEYMAN (Inside); age 20.—H. FOX wishes to highly recommend A. DRURY as above; three years in present place. Address, A. DRURY, Kenton Grange, Harrow, Middlesex.

JOURNEYMAN (Inside).—YOUNG MAN, age, 20, seeks SITUATION as above; 5½ years' good experience Inside and Out; excellent references; Bothy preferred. J. UNDERWOOD, Manor Farm, Stapleton, near Hinckley.

THOMAS PICKERSGILL can recommend ARTHUR MARSHALL as JOURNEYMAN; Kitchen Garden or Pleasure Grounds; 7 years' experience; age 23. Apply The Gardens, Sishes, Stevenage, Herts.

MR. BEEVERS, Stoke Court Gardens, Slough, wishes to recommend F. PANTON as JOURNEYMAN (Inside); 7 years with him; age 22; South preferred.

W. RING, Hamels Park Gardens, Buntingford, Herts, would be pleased to recommend a thorough good JOURNEYMAN (Second) in a good place; has been with me 5 years Inside; age 23.

W. THEOBALD, Hatchford Park Gardens, Cobham, wishes to recommend W. WEST as JOURNEYMAN (First); Inside; 2½ years here; good experience and references. Apply WEST, West Street, Ewell, Surrey.

H. VOSS, The Gardens, Swanspool, Wellingboro', can with confidence recommend W. BUCKLEY as JOURNEYMAN (Inside and Out); age 22; 3 years present situation; Bothy preferred.

GARDENER, married, seeks SITUATION; handy man, Indoors or Out; Wife help in house if required. BRISSENDEN, Elsing Hall, E. Dereham.

GARDENER, all-round man; married; middle age; no incumbrances; handy man; good personal character; 7½ years. WRIGHT, 29, North Road, Highgate.

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

THE KELWAY "ARTISTIC" BORDER makes a garden of enduring beauty, from early spring to late autumn, with a minimum of cultivation, and without the trouble of constant digging or bedding out. The plants composing the border are from strong country-grown stocks which will flourish under almost all conditions. Send dimensions of space to be filled, or write for Kelway's "Gardens of Delight" (6d.). The cost of the "Artistic" Border is 15s. or 25s. for 10 square yards.

KELWAY and SON, the Royal Horticulturists, LANGPORT, SOMERSET.

NOW IS THE TIME TO PLANT KELWAY DELPHINIUMS which have been improved almost out of recognition in the past twenty years. They produce plants ranging in height from four to eight feet, exceptionally hardy and with a rich profusion of choice blooms in all the shades of blue.
Choice named varieties, 24s., 36s. and 56s. a dozen.

KELWAY and SON, The Royal Horticulturists. LANGPORT, SOMERSET.

EVERY Gardener, amateur or professional, will find a large amount of useful information in the new edition of Kelway's "Manual of Horticulture"—the varieties, prices and culture of all sorts of garden plants, particularly those wonderful improvements raised in the Kelway Nurseries at Langport. A copy will be sent post free for 2s., which will be credited on the first order.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

KELWAY GLADIOLI flower freely in the open air through the autumn. Their fine bold blooms make an admirable addition to borders or beds and are invaluable as cut flowers for church or table decoration. Choice named collections, 3s., 4s. 6d., 6s., 7s. 6d., 9s., 12s., and 18s. a dozen.
Order at once.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

FIDLER'S NEW ILLUSTRATED CATALOGUE OF CHOICE GARDEN SEEDS will be sent, post free, to any address on receipt of post-card. Write at once for a copy. It may help you to save 50% on your seed bill this season. FIDLER and SONS, Royal Berks Seed Stores, Reading.

DELPHINIUM, Bendigo (Eames'), or Bella Donna Grandiflora, quite superseding the well-known Bella Donna by its very vigorous habits, producing quantities of bloom ...	1/6
GYPSOPHILA Paniculata fl. pl., the double white form; should be in every garden; strong ground roots	1/-
IRIS GERMANICA, Iris King, standards bright yellow, falls velvety purple edged gold ...	2/6
IRIS GERMANICA, Princess Victoria Louise, pale yellow standards with bright magenta falls, light edged; very striking	2/6
PHLOX DECUSSATA, for several splendid varieties see catalogue.	
SCABIOSA CAUCASICA PERFECTA, a splendid type of the well-known Caucasica, but much more vigorous	1/-
SCABIOSA CAUCASICA PERFECTA, Mrs. R. F. Felton, a soft silvery blue; perfect shaped blooms	1/6
AQUILEGIAS, long-spurred hybrids, embracing all the art shades; very strong roots ... ... 3/- doz.	0/4
PYRETHRUMS, Double, Queen Mary, a beautiful clear pink variety	2/6
PYRETHRUMS, Double, Lord Rosebery, crimson scarlet, extremely fine	1/-
PYRETHRUMS, Double, Yvonne Cayeux, creamy white, fine for cutting	1/-

The above three varieties are truly grand, being the pick of the double varieties, and the best in cultivation.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Cross Fertilisation.

Although every student of living organisms, plant or animal, recognises the great benefit which accrues from the introduction of fresh blood and consequent vigour by cross-fertilisation, as opposed to constant inbreeding, the full value of this and the manifold ways in which Nature contrives to secure it, is less popularly understood. In the plant world these contrivances have revealed themselves to every botanist. innumerable flowers demonstrating by their structure, and the different periods at which the pollen on the one hand and the receptive stigma on the other become capable of performing their mutual offices, that self-fertilisation is rendered either impossible or unlikely. As a result of this the services of the insect world, and even of the wind, become essential for bringing the two potencies together and so effecting the desired end. In other cases, such as the great primrose family, the form and arrangement of the pistils and stigmas differ in otherwise identical flowers, to the same end, and Darwin clearly demonstrated that when primula flowers of different structure were crossed the result was more and better seed than when self-fertilisation, i.e., application of pollen to the ovaries of the same flowers, was effected. In the animal world every breeder knows the evils of constant inbreeding within the range of one and the same strain in which the individuals are practically relatives, and even human laws have had, in the interests of the race, to be formulated, to prevent deterioration. On the other hand it is curious to reflect that all this occurs within more or less definite lines, outside of which Nature imposes distinctions restricting such cross-fertilisation to the limits of the species or closely allied ones, only rarely making exception, and that usually under very artificial conditions, in the case of genera. It is perhaps the selective and hybridising orchid grower of these later days who has most plainly demonstrated this possibility. Nature, unaided, undoubtedly now and again permits crosses between different species, with the result that wild plants are occasionally found which unmistakably display the combined characters of two distinct species, but as a rule these are rare and solitary, and in some cases it is an open question how far the difference and apparent combination may not be due entirely to mutation, or reversion to an ancestral type, which existed prior to the divergence by evolution, which produced the two species concerned from a common progenitor. How far the law of beneficial cross-fertilisation in plants has conduced to bring about the wonderful diversity of form, habit, and colour, which now constitutes our floral and vegetable wealth it is, of course, impossible to say, but there can be little doubt that the constant renewal of vital vigour must have played a material part in stimulating the response to insect influence, which has been the basis of improvement, while the influence of one plant upon another of the same species, but of some characteristic difference, must have contributed largely to varietal changes, and even to the production of definite sports which of late years have become recognised as probable evolutional factors of no mean importance. The slightest difference of structural tendency between pollen and the incipient seed which it fertilises, must of necessity lead to some sort of compromise, so to speak, in the offspring resulting from the conjunction. When we reflect upon the almost infinite complexity of potencies which must exist within the nucleus of every reproductive cell of a highly-organised individual, how it indubitably contains not merely the characters of its immediate progenitor but those of a long line of ancestors, all embodied in a microscopic bundle of filaments, and that the process of fertilisation involves the commingling of two of these of different origin, and therefore with different individualities, it is little wonder if now and again a new type of structure should arise, and that this, in successful hybrids between widely different specific forms or even generic ones, should be marvels of combination such as no human mind could have conceived or planned.

MR. R. W. WALLACE.

Mr. Robert W. Wallace, head of the firm of Messrs. R. Wallace and Co., of Colchester, will be well known to a vast number of our readers by reason of the evidence he has given of his wide knowledge of hardy flowers and the admirable manner in which he has staged the choicer subjects, on the lines of garden design, at the leading London and provincial exhibitions. Mr. Wallace is the son of the late Dr. A. Wallace, of Colchester, who was greatly interested in bulb culture, and made a close study of liliums. Mr. R. W. Wallace is an excellent all-round hardy plantsman, but his personal inclinations have drawn him to specially study Darwin and May-flowering tulips, irises, liliums, daffodils, aquatics, and alpines. Mr. Wallace is a member of both the Floral and Narcissus Committees of the Royal Horticultural Society; he has been a member of the Colchester Borough Council for seven years, and he is a member of the committee of the International Horticultural Exhibition of 1912. Still a young man, Mr. Wallace has many years of energy and usefulness before him, and we hope to see him win many more gold medals with beautiful and finely-designed exhibits of hardy plants and flowers in the years to come.

Foremen of the Royal Gardens, Kew.—From the "Kew Bulletin" we learn that, on the recommendation of the Board of Agriculture, the Lords Commissioners of His Majesty's Treasury have sanctioned the transfer of the foremen and storekeeper in the Royal Botanic Gardens from the temporary to the established staff, and Civil Service certificates have been issued for Messrs. G. Dear, W. Irving, C. P. Raffill, A. Osborn, T. W. Taylor, and J. Coutts.

The Miniature Japanese Garden, which formed an interesting feature of the Japan-British Exhibition, held at Shepherd's Bush, last year, is now installed in Battersea Park. At the close of the exhibition it was presented by the Municipality of Tokyo to the City of London, and the Corporation has handed it over to the London County Council. Briefly described, the garden consists of a miniature lake surrounded by dwarf trees of a type for which the Japanese cultivators have become famous, on ornamental banks, and decked with models of a medieval palace and shrines. None of the trees exceed 3ft. in height, and the majority are less than 1ft. One little juniper tree is stated to be 85 years old, and several other specimens are nearly as old, in spite of their small size. The species include Juniperus rigida and chinensis, Chamæcyparis obtusa nana, Acer pictum (Japanese maple), including one specimen 70 years old, Distylum racemosum, Cryptomeria japonica, a box; and several species of pine. The model garden is raised on a stand, which can be run on rails in and out of a shelter built in imitation bamboo work, according to the weather. The whole is protected by a wire cage. At present the little landscape presents a somewhat weather-beaten appearance, but will no doubt improve under the favourable conditions to which it is now subjected.

Hanley Horticultural Fete.—We are informed that owing to the federation of the six pottery towns, namely, Hanley, Stoke, Burslem, Fenton, and Tunstall (now called the County Borough of Stoke-on-Trent), there has been some delay in the preparatory work of this show, which is held under the direction of the Borough Council. The exhibition will be held on July 5 and 6, and the federation should materially enhance its success from all points of view.

National Chrysanthemum Society's Fixtures.—We learn that the N.C.S. will hold an exhibition at the Crystal Palace on October 4 and 5 of the present year, and its great show at the same place on November 1, 2, and 3. Floral Committee meetings will be held at Essex Hall, Strand, on September 4 and 18, October 23, November 20, and December 4; at the Crystal Palace on October 4 and on November 1; and at Carr's Restaurant, Strand, on December 18. The meetings of the General Committee will be held at Carr's Restaurant on September 18, October 23, November 20, December 18, and January 15 (1912), at 7 p.m.

Lenten Roses.—From the delightful gardens of Woodside, Chenies, the residence of Adeline Duchess of Bedford, Mr. Dickson sends us a gathering of flowers of Lenten roses, which are surprisingly beautiful, and of much interest as evidence of their value for contributing to the attractions of the flower garden thus early in the spring. The flowers, we understand, were gathered from seedlings raised from varieties of Helleborus colchicus, H. guttatus, and H. orientalis, and are remarkable for their large size and fine form, and for the wide range of colour they afford. They certainly represent a fine strain, and testify to Mr. Dickson's skill in their cultivation.

Primulas at Clandon Park.—Hardy primulas have been extensively planted at Clandon Park, near Guildford, during recent years, and with the semi-shaded and moist conditions provided for them they thrive remarkably well. Even at this early date the several large breadths of Primula denticulata cashmeriana and the white variety are full of bloom, and there are hosts of spikes yet to rise and open their flowers. Primroses and polyanthuses are coming into bloom, and already there is a shade of soft red over the breadths of Primula rosea produced by the first blooms. P. japonica follows much later, and by the light of the setting sun it paints the woodland crimson with its multitudes of spikes of brilliant flowers. The Earl of Onslow and his gardener, Mr. H. Blake, have achieved unusual success with hardy primulas and with irises at Clandon Park.

The Sweet Pea in the North.—Our Aberdeen correspondent writes: Much interest is being taken in the sweet pea in the North at the present time, and it is pleasing to learn that an exhibition of the flower is to be held in Aberdeen in August. The arrangements have been set going by an energetic committee, with Mr. James Esslemont as chairman, and Mr. M. H. Sinclair, the worthy secretary of the Aberdeen Chrysanthemum Society, as secretary. There will be competitions for professionals and amateurs, and a special section for ladies. The event is creating very great interest in many quarters, and there is every prospect of the exhibition being a very successful one. It will undoubtedly have the effect of stimulating the culture of the sweet pea locally. The sweet pea is more popular now than ever, and all over the country there is a growing interest in its culture, the Gardeners' Magazine taking no small share in the propaganda by means of the admirable number specially devoted to the flower some time ago, and the many articles and illustrations in other issues.

Alpines in their Native Haunts are always beautiful, and the subject is of great interest now that alpine plants and rock gardens are so much in the foreground of gardening. With such a subject as this to talk about, Mr. R. C. Reginald Nevill should secure a large audience when he lectures before the Royal Horticultural Society on March 28, at 3 p.m.

Royal Horticultural Society of Ireland.—This society has received a contribution of £5 from the Royal Dublin Society towards the prizes at the Winter Fruit and Flower Show, while to the same exhibition the Department of Agriculture will contribute prizes for apples totalling £60.

Rhododendrons from Leonardslee.—A few trusses of exquisitely beautiful and sweetly fragrant rhododendrons from Mr. W. A. Cook, gardener to Sir Edmund Loder, Bart., Leonardslee, Horsham, once more emphasises the value of the early-flowering Himalayan species in sheltered southern gardens, and incidentally reminds us of the extent and comprehensiveness of the rhododendron collection at Leonardslee. Among the flowers received, those of R. ciliatum, R. Dalhousiæ, R. Fosterianum, and the campanulate white-flowered R. Falconeri are exceptionally fine.

Boskoop Flower Show.—We have on several occasions referred to the great exhibition of forced shrubs and plants which will be held at Boskoop from April 5 to 16, and we again refer to it for the purpose of acknowledging the handsome poster that has been sent us. The occasion of the exhibition is the jubilee of the Pomological Society of Boskoop, whose members now devote themselves almost wholly to work other than pomological.

Lord Pentland on Gardening in Lewis.—In the course of an interesting address in connection with the Town Planning Exhibition in Edinburgh, Lord Pentland, the Secretary for Scotland, made a strong appeal for gardens, and stated that even the cottars and crofters of the Island of Lewis had begun to see the benefits of cultivating vegetables and to realise the beauty of flowers. Visitors to Lewis have often remarked upon the sordid appearance of so many of the dwellings of the crofters and cottars caused by the absence of gardens, and they will be glad to learn that a change is in progress.

The Carnation Year Book for 1911 is especially welcome for the evidence it affords of the continued success of the Perpetual-flowering Carnation Society, of which it is the official publication, and the increasing popularity of the flowers to which it gives its attention. It is satisfactory to observe that there is a continuous increase in the membership, and that the society was able to hold two exhibitions, and to close the year's work with a substantial balance in hand. Lists of new carnations registered during the past year by the society and the American Carnation Society are given, and these are of interest as evidence of the continued activity of raisers in the production of new forms. There are numerous articles on the several aspects of carnations written by well-known cultivators, and there is a communication from Mr. C. H. Payne, in which some of the older British and Continental books on carnations are passed under review in his best style.

Shot-hole Fungus (Cercospora circumscissa), to which we have on several occasions directed attention, is dealt with at some length in a leaflet (No. 247), which has just been issued by the Board of Agriculture. This fungus attacks the leaves of the peach, almond, cherry, apricot, and nectarine, and, occasionally, those of the plum. According to the leaflet, Dr. W. M. Scott, of the United States Department of Agriculture, has found that the fungicide known as "self-boiled" lime-sulphur mixture, can be used as a spray on the leaves of peach trees without injury to them. The proportions for a mixture ready for use are 8lb. lime, 8lb. sulphur, and 50 gallons of water. Directions are given for the preparation and application of this fungicide.

National Auricula Society.—The Midland section of the National Auricula Society will hold its annual exhibition in the Botanical Gardens, Edgbaston, on May 3 and 4. The schedule is comprehensive and affords abundant opportunities for cultivators of these beautiful flowers to demonstrate their skill.

WATERSIDE PLANTS.

The divisional line between acquatics and waterside plants is not easily defined, and except in a few that readily occur to everyone, the majority of plants that custom bids us assign to the water proper may equally well be grown as land plants, hence it comes that these terms have chiefly a descriptive value, and cannot be adhered to. A definition of water-side plants would naturally lack consistency for this very reason, so that the subject in its broadest sense admits practically any plant capable of adding to pictorial effect in the general scheme of a water garden.

A narrower limit, however, is more in accordance with accepted ideas as regards what constitutes waterside plants, and, in practice, the results are eminently most satisfactory and altogether pleasing when a few well-chosen subjects are carefully placed, with the idea of securing strong contrasts and broad effects, but the tendency to overload a water garden for the sake of variety alone should be sternly discouraged at all seasons.

[Photo: C. P. Raffill.

WATERSIDE IRISES (I. SIBIRICA) AT KEW.

Waterside plants resolve themselves naturally into two series; those introduced for foliage effect alone and those in which interest centres in the flowers; at the head of the latter group stands Iris Kæmpferi (lævigata) commonly known as the Japanese iris, in which the flowers are of two kinds, and are somewhat erroneously spoken of as single and double, owing to the abnormal development of the inner segments in the latter; in both forms, the colours are rich and varied, and in the duplex form the flowers are of the most sumptuous character. This iris is tufted in habit, with flat leaves that stand erect; it develops an enormous fibrous root system that strikes deep into any rich moist soil; planted with the crowns a foot above water to which the roots have ready access, the maximum development of the plant is assured, and if planted in extensive drifts, this iris is difficult to surpass in beauty when in flower, during July. All the varieties of Iris sibirica succeed under similar conditions, and, in addition, Iris aurea, I. gigantea, I. Monnieri, and the varieties of I. Monspur may also be included, being alike distinct in leaf and flower.

Astilbes are an extensive group, with elegant spiky inflorescences ranging in colour from white to pink, while in Davidi the flowers are rosy-purple, and among the last to open. The leaves of all are compound and much divided, above which the flowers appear in sheaves; they succeed in damp ground, and may be treated as actual wet-ground plants in summer. Dwarf kinds like Silver Sheaf, Queen Alexandra, and Peach Blossom, are charming in masses close to and slightly raised above the water margin, while A. grandis, A. Davidi, A. rivularis major, and A. Thunbergi are effective plants to place in bold positions, planting several together so as to form a group. Spiræas call for similar treatment to astilbes, but the flowers being mostly in flattish heads renders them distinct, while in S. venusta and S. palmata the flowers approach a deeper shade of crimson than at present obtains in astilbes. Spiræa camschatica (gigantea) is a plant of giant stature, frequently attaining a height of 8 to 10ft. when given suitable conditions; the variety rosea is less vigorous, but most desirable owing to the soft pink shade of the flowers. S. Aruncus produces creamy flowers in erect, branched panicles, and is a most effective plant for a bold group. S. ulmaria fl. pl. gives creamy-white double flowers, carried on light stems above mounds of delicately cut leaves.

Senecios are strong growing herbaceous plants, requiring considerable space for development, yet of the highest importance in any waterside scheme. S. japonica has cut leaves and orange-yellow flowers; in S. Clivorum the leaves are rounded, and the orange-yellow flowers are produced in August and September on stout branching stems. S. Wilsonianus has lemon-yellow flowers on erect spikes. Ligularia macrophylla is close related to senecio, and the first of this group to flower, it is also most distinct, owing to the paddle-shaped leaves and their striking colouring of grey-green. Polygonums succeed in any heavy, damp soil, and are valuable as autumn-flowering plants, but, owing to their aggressive character, are best grouped by themselves. P. sachaliense and P. Cooki are giant kinds, reaching a height of 8 to 10ft.; P. oxyphyllum and P. cuspidatum range in height from 5 to 7ft., while P. alpinum and P. virginianum are moderate growers of an average height of 3ft. or so. The flowers, in every instance are white, and produced with utmost freedom in branching cymes.

Calthas or "King Cups" revel in rich mud close to the water edge, and while the single flowers of C. palustris are not without merit, the double form is much more lasting, while C. monstrosa plena and C. polypetala are equally desirable, the latter having exceptionally large leaves. The water Forget-me-not should also be placed along the margin, and Mimulus cupreus Brilliant is a subject of the highest merit for a similar place, as the rich crimson flowers that are borne in July and August completely smother the plant. Lythrum salicaria attains a height of 4 to 5ft., and is also adapted for the water edge, while any wet boggy ground will suit it equally well: roseum superbum is the oldest form producing stout, erect stems with deep red flowers in August and September; there is also a very excellent form with lighter pink flowers, but it is best grouped apart from the darker shade.

A number of primulas are partial to wet ground, and are most effective when grouped in quantity. P. rosea is first to flower, generally unfolding its rich pink flowers in April and May. P. japonica, when of the true crimson form, is superb massed in quantity beside water, and the newer P. pulverulenta has merit in the same direction. P. sikkimensis and P. Cockburniana massed together produce a most pleasing and altogether unique effect with the orange and lemon flowers mingled. Trollius europæus, in all its forms of lemon, yellow, and orange; Ranunculus aconitifolius, dodecatheons, and Primula cortusoides form a group of spring flowering plants capable of the best effects when introduced into waterside planting, and in a choice spot, with some light shade; and where the conditions are not too damp, cypripediums, ferns, and swamp lilies would produce a feature of uncommon interest, and with these one would naturally associate Meconopsis Wallichi and M. integrifolia, alike for their wonderful flowers and charming leafage.

Of waterside plants employed for their foliage effect, bamboos maintain a foremost position on account of their extreme elegance and great hardiness; the kinds that succeed under the greatest variety of conditions include Arundinaria anceps, A. aristata, and A. nitida (Bambusa fastuosa), Phyllostachys aurea, P. flexuosa, P. nigra, P. Quilioi, and P. viridi-glaucescens, while among dwarf kinds Bambusa palmata should be included for its strong, bold leaves. All are most effective in bold groups, and with the tall kinds occasionally coming to the water-edge and overhanging, the effect has somewhat of a tropical character. Gunneras are plants of majestic proportions, and when suitably placed beside water, command instant attention and invest their surroundings with quite a distinct character. G. manicata is the most superb species, and should always have precedence where space admits; G. scabra is also desirable, and has the merit of adapting itself to more restricted conditions; both enjoy a soil of the richest character, and are best planted with the crowns well above water level, yet in such a position that the roots may have ready access thereto.

Rodgersias succeed in rich, moist soil, and rarely exceed 3ft. in height. R. podophylla is the oldest plant, with magnified horse-chestnut-like leaves that are richly coloured purple-crimson in autumn. P. pinnata alba is quite distinct, and has some merit over the former as a flowering plant, but the foliage is less interesting. Saxifraga peltata prefers a wet spot; the characteristic umbrella-like leaves are supported by long footstalks, which spring directly from the rhizome; the flowers are invariably produced early in the year before the leaves appear.

Of foliage plants with compound leaves available for waterside planting heracleum, Oreocome Candollei, and Cynara Scolymus are most ornamental, the latter in particular, on account of the bright silver-grey of the leaves. The first-named succeeds in wet ground, the others in soil that is well drained.

No water garden is complete without its complement of reeds and grasses; of these carex, cyperus, and eulalias include some interesting and desirable kinds, and the free-flowering forms of Cortaderia (Pampas grass) may also be worked in to great advantage. Elymus giganteus glaucus is a low grass, with intense grey-green glaucous leaves, and this striking leaf colouring is also present in the form of the great reed known as Arundo macrophylla glauca.

Thomas Smith.

AUTUMN FLOWERS IN THE ROCK GARDEN.

The rock garden during the autumn months is considered by many to be devoid of interest owing to the few plants flowering there at that season of the year. It is true that many plants may be found that do flower in the autumn, but the majority are of the aster and sunflower type, too large and totally unsuitable for the rock garden.

Flowers, however, are not the sole source of interest in the rock garden, for what could be more attractive and beautiful than the silvery rosettes of many of the saxifrage family, such as S. longifolia, S. cochlearis, S. lingulata var. lantoscana, and the endless forms of S. Aizoon. Then, again, there are the lovely green carpets formed by those of the mossy section of the genus, S. hypnoides, S. decipiens, and S. muscoides. Among those plants having handsome foliage that assumes such lovely shades of colour in the autumn months we have the shade-loving Galax aphylla, Shortia galacifolia, with the various species of Rodgersia, among others.

There is also an infinite variety of form and outline to be seen in the numerous subjects that find a place in the rock garden, so that even when not in bloom they are very attractive at all times. Among the few suitable plants for this purpose that flower in the autumn are: Anemone japonica, which although not usually considered as suitable for this purpose, should always have a place found for it among the taller-growing plants at the back, where it will not look out of place, and help to brighten the dull days with its beautiful flowers of various shades of white and rose. A. vitifolia is a Himalayan species, with leaves of greater substance, but rather smaller white flowers. Aster Thomsoni is one of the few Michaelmas daisies with a dwarf erect habit. It is a most persistent flowering plant, with light purple flowers, produced well into November. Others of the genus worthy of a place on account of their neat appearance are the rich violet coloured A. grandiflorus and the white-flowered A. Porteri, which comes from the Rocky Mountains of Colorado.

Most of the members of the beautiful campanula family are well over by the autumn, only a few prolonging their flowering period so late. C. punctata is an interesting species from China and Japan, with large, drooping white flowers spotted with red. C. sarmatica is a pretty species from the Caucasus with pale blue flowers on stems about a foot in height. Ceratostigma plumbaginoides, belonging to the Plumbago family, is a very desirable subject, and bears its bright cobalt blue flowers very freely during the autumn months. At the same season the leaves, borne on long pendant stems, change to a beautiful red shade, making it additionally attractive. Cimicifuga simplex, a September flowering species, might with advantage be introduced into the shady parts of the rock garden, for its drooping, feathery racemes of white flowers are very elegant. It is a native of Japan, and grows from 2ft. to 3ft. high, with much-divided foliage. A smaller kind, with erect spikes, is C. japonica.

Several species of gentians prolong their flowering season into the autumn, namely, G. Andrewsi, the "Closed Gentian," from North America, with terminal clusters of rich blue flowers. A peculiarity of this species is that the flowers do not open. G. scabra, or G. Fortunei, as it is sometimes called, is a native of Japan, growing over a foot in height, with blue flowers, spotted with white in the throat. Others are G. straminea, with greenish-white flowers; and some of the forms of G. septemfida, which is one of the finest of the gentians, with beautiful blue flowers freely produced. For making a carpet of foliage to cover roots or rocks few things are more suitable than Polygonum affine. During the whole of the autumn the spikes of rosy-crimson flowers are produced in abundance, and form quite an attractive feature, as they last a long time in good condition. Somewhat smaller in foliage, and with long trailing stems, is P. vaccinifolium, also from the Himalayas. It loves to ramble amongst stones, and bears a profusion of slender spikes of rosy-pink flowers. Both should be allowed plenty of room to spread.

Members of the large and beautiful Primula genus commence to flower in March, among which is P. denticulata, while others keep up the succession till the late autumn. Among the later-flowering ones are P. luteola, from the Caucasus, with bright yellow flowers; P. grandis from the same region, with small yellow flowers; P. mollis, hardy in sheltered situations, and bearing rosy dark-eyed flowers in August and September; and the Chinese P. Poissoni, with rich purple flowers in whorls. All these grow well in moist shady situations. The saxifragas, like the primulas, extend their flowering period over the greater part of the year. Only two, however, are autumn-flowering, these being S. Fortunei, from China, with handsome rosettes of glossy leaves, and large panicles of white flowers with unequal petals, the stems growing about one foot high; and S. cortusæfolia, from Japan, which is somewhat similar, but with more deeply notched leaves and rather smaller flowers. They are both very effective, and well worth the little protection they need during the winter.

Many of the sedums prolong their flowering season into the autumn, some of the best for this purpose being S. maximum, a vigorous species with bronzy foliage, S. Sieboldi, and the well-known S. spectabile. Tricyrtis hirta, the "Japanese Toad Lily," bears a curious but interesting flower, speckled with purple on a pale ground, in September and October. Very similar is the Himalayan T. pilosa. Zauschneria californica, the "Californian Fuchsia," is one of the showiest of our autumn flowers, with its brilliant vermilion coloured trumpets. An earlier-flowering form is the variety mexicana. This is more valuable than the type, giving as it does a longer period of blooming before the frost comes.

Many other plants might be added to this list, like Callirhoe lineariloba, Corydalis thalictrifolia, Cyananthus lobatus, Cyclamen neapolitanus, Malvastrum Munroanum, and Silene Fortunei. Among bulbous plants there are Colchicum speciosum, C. variegatum, C. autumnale, Crocus speciosus, C. medius, C. zonatus, and C. longiflorus, among many others. W. Irving.

DARLEY DALE, DERBYSHIRE.

PERENNIAL ASTERS.

These, popularly known as Michaelmas Daisies or Star Worts, were until a few years ago, generally regarded as amongst the most uninteresting classes of plants cultivated in our English garden, and amongst those who so regarded them was myself. At the same time, I was under the impression that there was a great future for them. if seriously taken in hand, and I resolved at the earliest possible moment to make as complete a collection as I could of all the known varieties. This I did. and made a selection of the best kinds to grow for seed-saving purposes.

At first I met with but little success, very many of the seedlings proving worthless or no better than the existing varieties, but undaunted, I persevered, and am now more than satisfied with the result. Others, too, I am glad to know, have proceeded on the same lines, and introduced many sterling novelties. With the many improved forms these asters make one of the most valuable groups of autumn-flowering plants we possess, and nearly every garden, large and small, cultivates them more or less. With a reasonable amount of care, owing to their hardiness, a wealth of blossom is assured during the autumn when practically the beauty of all else in the open borders is on the wane. They flourish in almost any situation, and on any kind of soil, and may by proper management be successfully grown on the same site for a long number of years. Their delightful and graceful habit and free flowering propensities of many shades of colouring when judiciously arranged, present a glorious picture from the beginning until the end of October. In addition, they are admirably adapted for dinner-table and other forms of house decoration.

PORTION OF BORDER OF MICHAELMAS DAISIES.
At Aldenham House, the residence of the Hon. Vicary Gibbs.

To obtain the best results the Michaelmas daisies should annually be taken up at this season and replanted, and though they are admirably adapted, especially some species and varieties, for dotting about in the herbaceous borders or shrubberies, unquestionably the best plan is to devote either a good border or several beds entirely to their accommodation. Overcrowding must be strictly avoided. This is detrimental to their well-being in several ways, as not only is it impossible to stake them out properly, so that they display their charms to the best advantage, but also when the growth is crowded attacks of mildew are difficult to prevent. We plant at a distance of three feet from plant to plant and four between the rows, and arrange them angle ways in the rows to admit of their having ample space to develop.

Select strong pieces for planting, not too large, and those exhibiting the most promising growth. If the land is very heavy and tenacious, the smallest plants will be benefited by having a sprinkling of finer material about the roots. Plant firmly and label each variety correctly and neatly. After planting fork the border over and leave it in a neat and tidy condition. Where slugs are prevalent they will at times play havoc with the young growth, so that a sprinkling of fine cinder ashes round each will be useful as a protection from them. Staking is an important detail to ensure their producing a pleasing effect when in bloom. Many growers think that one stick suffices, and they put one in the centre and loop the whole of the growths to it, but this completely spoils the effect because the graceful habit is lost.

If time can be spared, and it is not a very large undertaking, three or four, or even five, stakes would be placed to each specimen. They should be inserted in a slanting direction, the tops pointing outwards. Drive them into the ground as near to the base of the plant as can be conveniently done without damaging the roots, and to reduce the risk have the stakes well sharpened. Staking should be done before the growths become too long. If left there is the possibility of some being broken.

Thin out the growths to one or two at the most to a stake, and tie with a piece of raffia.

If any of the shoots are unduly long in comparison to the others these may be stopped, or if the plants are preferred of dwarf habit stop the whole, but, generally speaking, I do not recommend stopping all the growths. Little attention will be required after staking is completed beyond tying the shoots at intervals and loosening the surface with the Dutch hoe. The latter is, of course, quite essential to their well-being, and also checks the weed growth, and in dry weather prevents rapid evaporation of moisture from the ground. On light soils, especially in dry weather, much assistance will be derived from copious supplies of moisture at the roots, and a mulching with manure or long strawy litter. An occasional watering with sewage water will also prove of much benefit, and a sprinkling of artificial manure on the surface in showery weather will prove stimulating.

Asters, as a rule, are not prone to many diseases; their chief enemy is mildew. Some varieties are more liable to attacks of mildew than others, and it is worthy of mention that of all the plants of Climax I have grown, in all positions, I might say, and aspects, I have never once seen the slightest trace of mildew. Syringing during the evening with an approved specific is the best remedy, using a syringe capable of producing a fine spray, and thoroughly moistening the whole of the plant, and give a good syringing in the morning with clear water.

When the growth is completed, just prior to expanding their flowers, remove the tops of the sticks with a pair of cutters; this will greatly enhance the effect. The varieties and species of asters, as I stated before, are various, both in regard to habit of the plant and colour. Their season of flowering, too, may be made to extend over quite a long period, if the various species are planted in the mixed borders, but where grouped to themselves, only those should be used that flower about the same time. The Amellus section include now many shades of colour, and have of recent years been much improved upon. These are invaluable for cutting, and should occupy a position apart from the aster border proper. A. Thomsoni flowers in August, and is well worth a position in the garden. Flowering immediately afterwards is A. acris, a good border plant, usually much admired. Of this, too, there are now many beautiful varieties. A. cordifolius and its several varieties contribute many beautiful plants, principally of blue shades of colour. A. cordifolius elegans, Ideal Diana, and White Diana, Little Boy Blue are all worth growing. Of the A. ericoides section there are many varieties, and these universally find favour, because of their small flowers, so freely produced and of varying shades of colour. To enumerate all the varieties that are of merit would be impossible, but a few well worth a position might include: Bianca, a pure white form of Hon. Edith Gibbs; Delight, white; Enchantress, blush, with yellow centre; Golden Spray, good for the front row; Hon. Edith Gibbs, one of the best, pale blue; King Edward, dwarf, bright mauve in colour; Osprey, another good variety for the front row, pale pink. Perfection is a grand free-flowering aster of perfect growth and medium stature, with pure white flowers. Ringdove is an excellent variety, a seedling from Enchantress, with rose-lavender flowers. Simplicity is a graceful front-row plant, bearing flowers of a pale blue colour. Star Shower is a good creamy-white variety, very free, dwarf to medium in height. Novelty has blue flowers, and is highly meritorious. Desire is one of the most distinct. In habit the plant is pyramidal, and the growth completely covered with small white flowers.

Of the Novæ-Anglæ section there are many useful varieties. Probably one of the best known is Mrs. F. W. Raynor, an indispensable variety on account of its colour—bright red. Lustre is a striking variety hardly so bright in colour as the former, but the flowers are distinctly semi-double in character and quite new. The Novæ Belgi section is a large one. Of this section probably no aster has gained such popularity as Climax. This is of vigorous growth, grand in colour, and invaluable for cutting. St. Egwin is another good dwarf variety of the section, with flowers of a pleasing pink shade. Finchley White, a distinct and good white; Esther, a good late pink variety, makes a good plant for the herbaceous border, as does A. Tradescanti, late; A. vimineus, and varieties compacta, Lovely, nana. A. turbinellus and its white variety are also distinct and worth including.

E. Beckett.

PICEA EXCELSA RAMONTI.

A handsome small-growing variety of the common spruce. The specimen illustrated is about two feet high.

NEW PLANTS, ETC.

ODONTOGLOSSUM JEANETTE

This is a delightful hybrid produced by crossing O. Rossi rubescens with O. amabile heatonense. The flowers are of good size and fine texture, and the prevailing colour is deep vinous purple, the apices of the segments being rosy. The curious lip has a bright rose-coloured apex, and a yellow base and crest. A handsome and distinct orchid. F.C.C., R.H.S., March 14. Messrs. Charlesworth and Co., Haywards Heath.

ADIANTUM GLORY OF MOORDRECHT.

To this graceful adiantum, already described and figured in these pages, the higher award was granted on this occasion. F.C.C., R.H.S., March 14. Mr. A. A. Fabius, Emsworth.

CYMBIDIUM GOTTIANUM.

A very pretty hybrid between Cymbidium eburneum and C. insigne Sanderi. The flowers have a good deal of the substance and form of the first-named parent, and were carried on an erect spike. The ground colour is white, with green tinted sepals and rose-red spots on the yellow crested lip. A.M., R.H.S., March 14. Messrs. Sander and Sons, St. Albans.

CYMBIDIUM ALEXANDERI.

This is another hybrid from the comparatively new Cymbidium insigne, the other parent being C. eburneo-Lowianum. In this case the large flowers were white, tinged with pink, and with lines of a deeper hue, while on the lip were spottings and stripes of deep red. A.M., R.H.S., March 14. Lieut.-Col. Sir G. Holford (grower Mr. H. Alexander), Westonbirt, Gloucester.

ODONTOGLOSSUM MIRUM BRAGGENSE.

A very attractive odontoglossum derived from a heavily blotched O. crispum and O. Wilckeanum. At first sight it could easily be taken for a finely blotched crispum. The white ground colour is almost obliterated by the large blotches of rich red-purple that extend over sepals, petals, and lip. A.M., R.H.S., March 14. Messrs. Sander and Sons, St. Albans.

LÆLIO-CATTLEYA DOMINIANA MONK-END VAR.

This particular variety of L.-c. Dominiana has very large flowers; their sepals and petals are deep lilac and the broad rounded lip is intense and rich purple. A.M., R.H.S., March 14. Mr. H. A. Innes, Croft Spa, Yorks.

TULIP YELLOW MURILLO.

The Murillo set of double tulips is very popular and this new yellow form promises to be of great value for forcing as well as bedding. The flowers are of good size and substance, well doubled, but not heavy, and their colour is bright yellow. A.M., R.H.S., March 14. Mr. W. Profittlich, Twickenham.

SAXIFRAGA PETRASCHI.

A charming little saxifrage, bearing pure white flowers over a close mass of glaucous leafage, and on red-tinted stems. It is a hybrid between S. tombeanensis and S. Rocheliana. A.M., R.H.S., March 14. Sir Everard Hambro (gardener, Mr. Grandfield), Hayes Place, Hayes, Kent.

HIPPEASTRUM QUEEN MARY.

A very fine and altogether beautiful variety, white, with blooms measuring eight inches across. The segments were all broad and rounded, making up flowers of excellent form. A.M., R.H.S., March 14. Messrs. R. Ker and Sons, Liverpool.

DWARF CONIFERS FOR THE ROCKERY.

The various dwarf conifers are excellent subjects to introduce into the rock garden, for they add the necessary touch of greenery and height which is required to relieve the bareness of the garden during winter, while their slow growth and low stature when mature effectually prevents them from offering any serious obstruction to small choice plants in their immediate neighbourhood.

If planted when quite young many of them may be accommodated in small pockets between large stones, for the roots push their way about and manage to obtain sufficient nourishment to keep the plants going. When, however, old plants with a considerable root system have to be introduced, positions must be found where there is a good depth of soil, or they will not establish well, and the result will be an untidy appearance by reason of dead branches and diseased foliage.

The common Spruce, Picea excelsa, provides a number of varieties which are well worth growing, for they form dense green cushion-like masses from nine inches to three feet in height. Some grow very slowly and are many years in attaining a diameter of two feet. Good ones are compacta, diffusa, dumosa, globosa nana, microsperma, pygmæa, Ramonti, and repens. Clanbrassiliana is also of dwarf habit, but is more vigorous than the other kinds. Other species also produce dwarf varieties, and P. orientalis nana, P. o. pygmæa, P. alba compacta, and P. a. echiniformis, are good ones to grow.

Among the pines are several very useful forms. For a group about the back of the rockery the dwarfer forms of the Mountain Pine, P. montana, come in very nicely, while the common Scots Pine, P. sylvestris, gives us low-growing compact varieties in globosa, nana, and pumila. Aurea grows very slowly, and people who like a touch of gold here and there might try that variety. The Weymouth Pine, P. strobus, adds to the number of dwarf, compact-growing kinds, with compacta, densa, and nana, whilst a dwarf type of a distinctly different character is brought to notice in P. s. prostrata. In this the branches are scandent, and they may be made to lie on the surface of rocks or hang over the face of a cliff.

Several species of pinus are so slow growing that they may well be used in the rock gardens. Such kinds as edulis, cembroides, and albicaulis are of the number.

Though the Douglas Fir, Pseudotsuga Douglasi, may be considered as one of the giants amongst conifers, it produces a dwarf compact-growing variety, which is variously known as nana and pumila. It may well be introduced for the sake of variety. Amongst junipers there are several very useful subjects. The common Savin, Juniperus Sabina, may be used on the outskirts of a rockery, especially where the soil is of a chalky nature, while for more prominent places the varieties prostrata, procumbens, humilis, and Knap Hill variety are all available. The variety procumbens is known as the "Waukegan juniper," and is peculiar on account of the curious purplish hue assumed by the foliage during winter. Other junipers which may be used with success are J. communis. and its varieties aurea, fastigiata, and hemisphærica, and J. littoralis, a Japanese species of prostrate habit.

Among the yews are one or two kinds which may well be placed on the rockery, for they rarely grow more than from one to three feet high. The tiny-leaved varieties, epacridioides and ericoides, are neat-growing kinds, while nana is of more or less prostrate habit. Podocarpus alpina, a Tasmanian shrub, may be requisitioned in the southern counties. It grows about three feet high, but as it spreads rather widely, a fair amount of room should be given.

Of Lawson's cypress there are several dwarf varieties of globose habit; the most suitable for the purpose under notice are Cupressus Lawsoniana vars. compacta, minima glauca, and nana. The Japanese Cupressus obtusa provides several varieties of more than general interest, which are suitable for the rock garden, for though they sometimes grow taller than many of the kinds previously mentioned, they are not of very dense appearance, and their peculiarity of habit well fits them for the position. C. o. compacta, C. o. nana, C. o. nana aurea, C. o. nana gracilis, and C. o. pygmæa, are the dwarfer-growing kinds, whilst the taller filicoides, gracilis, lycopodioides, and tetragona aurea, are all worth attention. Cupressus thyoides, the White Cedar of the Eastern United States, produces a very dwarf compact growing variety in leptoclada nana, but it is rare and difficult to obtain.

The American Arborvitæ, Thuya occidentalis, is to the front with a number of dwarf forms, dumosa, globosa, ericoides, Hovei, and Späthi, all being of this class. T. plicata also gives us a low-growing variety in compacta, whilst the Japanese T. dolobrata produces a dwarf form which is called nana. The Chinese Arborvitæ, Thuya orientalis, gives us low compact bushes in the varieties compacta, densa, ericoides, globosa, and minima, while Libocedrus decurrens has two dwarf representatives in compacta and nana. Cryptomeria japonica, the Japanese Cedar, produces several curious dwarf varieties, such as elegans nana, Lobbi nana, and spiralis; they are, however, more curious than beautiful.

Although it is possible to find more dwarf conifers than those contained in the above list, the ones mentioned are sufficient to direct attention to the many plants which may be used for the purpose under notice.

W. D.

THUYA OCCIDENTALIS DUMOSA.

A dwarf, dense-growing variety of the American Abor-vitæ, with brownish foliage. The specimen illustrated is about fifteen inches high.

Chorizemas.—These pretty hard-wooded plants are remarkable for their brightly coloured blossoms, which are borne during the winter and spring months. The pea-shaped flowers are usually of some shade of red or yellow, generally a combination of the two. They are all natives of Australia, and, with one exception, are not at all difficult to cultivate, needing as they do a compost made up of fibrous peat and sand, firm potting, effective drainage, and an ordinary greenhouse temperature. There are several kinds, one of the best being Chorizema Lowi, a garden form distributed about twenty years ago. This has richly-coloured blossoms, and dark green prickly leaves. C. cordata splendens, a stronger grower, is also good, while C. flava has self yellow flowers. C. Henchmanni is now very scarce, being a difficult plant to grow well.—W. T.

SPRING PLANTING IN THE ROCK GARDEN.

Many alpines require the most careful planting, both with regard to method and also to their situation, and the full consideration of these points is necessary if even a moderate measure of success is to be achieved within a reasonable time. It is, for example, a blunder to plant alpines too early, as many are extremely small, and easily disturbed by the late frosts, which work such havoc in our springs, while leaving the process until late autumn is quite as, if not more, risky. It may be said that showery weather from April to September will give these subjects the best chances, and the "month of smiles and tears"—April—is one of the best for our purpose. Some of the earlier alpines will have gone out of bloom; others will still be in flower, and still others have yet to develop their blossoms, but in April and in showery weather in May, all of these may be planted with every confidence of success. It is only necessary to examine a plant which has been put in position in April and to compare it with one set in, say, September, to discern the vast difference in favour of the April one in the following summer. Thus, one would advocate April planting in preference to any other time.

[Photo: H. N. King.

A FINE GROUPING OF SAXIFRAGAS IN THE ALPINE GARDEN AT GATTON PARK, REIGATE,
The residence of Sir J. Colman, Bart.

In planting the alpine flowers, it is necessary to have at hand some suitable compost, as well as to see that the positions the flowers are to occupy are properly prepared. A good compost for the greater number of plants will consist of about equal parts of loam and leaf-soil, with some sharp sand and some grit added. This may form the basis of our planting material, but a little variation in the proportions of each will not matter much. This compost ought to be free and open, so as to admit of its being well rammed in about the roots without becoming unduly stiff for the latter. It ought to be just moist enough to cling together if pressed in the hand, but not so much so as to be clayey and wet when thus handled. In fact, soil such as is used for potting ordinary plants will answer well if in the same condition.

The sites for the alpines must be well drained, and a simple hole in a rock or stone without any drainage will be destructive to the greater number of plants. Where such a hole has to be utilised provision should be made for carrying off the surplus water below the ground line, so that the roots may be in a medium free from stagnant moisture. In such a hole drainage material should also be provided. Then the sites for the plants should be so arranged that the rainfall and the overflow from above should be conducted towards their roots. Many alpines which dislike moisture above revel in this when at the roots, and a little planning of the sites for the individual plants will be found of the utmost value. Such places as pockets or crevices which are overhung by stones should not be planted unless the alpines can receive a sufficient supply of moisture in some way or other. To plant flowers where the earth is always dust-dry is to court failure, and even the most drought-resisting sempervivum will look far from happy in such a place.

Then it is necessary to provide positions suitable for the alpines it is intended to plant. It is hopeless to attempt the cultivation of shade-loving subjects, such as ramondias and haberleas on a dry, sunny rockery, just as sun-lovers will fail to give satisfaction in some gloomy corner overhung by trees. So, also, a lover of moisture ought to have prepared for it some low position with plenty of water, where it can never suffer from drought.

Keeping in view these points and having our plants at hand, we may proceed to put them into position, having also beside us a supply of limestone chips or old broken mortar for the lime lovers, together with some small pieces of stone and some larger bits to lay round the plants. If the plants are in pots they should be turned out, and the ball gently broken up. If filled with roots these may be partially loosened round the sides so as to give the alpines an earlier hold of the earth. A hole of sufficient depth to hold the plant is then made, and the plant inserted, keeping in most cases the crowns a little below the ordinary level so as to allow of top-dressing in future seasons. The earth should then be well rammed in about the roots, and made really firm, though not stiff, and some small stones jammed in about the plants. If the rockery has open spaces of any size about the plants a few stones ought to be placed round about the latter to prevent rapid evaporation.

The question of what to plant is a large one, requiring more space for detail than can now be afforded. Much will depend on the position and nature of the rock garden and upon the exposure or exposures it presents. If it is overhung by trees, it is one of the very worst.

For certain positions, however, certain plants ought to be secured, and with reasonable care these have every prospect of success. Aubrietias are indispensable for spring bloom, and, while many do not care for the arabises, as comparatively common, there are a few choicer species, such as A. Sturi, which will give pleasure. Arenarias, again, must not be forgotten, and A. balearica, for the shadier stones, with A. montana for the sunnier parts, will never come amiss. Such choice geraniums as G. argenteum and G. cinereum, with G. lancastriense, and a few of the choicer erodiums, such as E. guttatum and E. sibthorpianum, will give pleasure in summer.

[Photo: H. N. King.

BEAUTIFUL HERBACEOUS BORDERS AT CLANDON PARK, GUILDFORD.
The residence of the Earl of Onslow.

The little shrubby helianthemums, or sun roses, are delightful shrubs; and a choice broom or two, like Cytisuses Ardoini, C. kewensis, and C. Beani add charm to the rock garden. Androsaces may be represented by A. carnea, A. lanuginosa, and A. sarmentosa, as easy growers. Synthiris reniformis is a good early alpine; and in the dianthus family we have a host of beautiful alpines, D. neglectus and D. petræus may be named at random, together with the choice D. alpinus. Ramondias and haberleas have been alluded to as good for the shady parts, and we may have Galax aphylla and Shortias uniflora and galacifolia for the lower moist places, with the delightful Polygala buxifolia. Then there are the almost myriads of saxifrages of many forms and colours, indispensable everywhere; with sedums, sempervivums, iberises, silenes, soldanellas, saponarias, gypsophilas, and, in fact, a bewildering array of flowers of all kinds.

It is not so much a question of what plants are available as of selecting among so many choice alpine flowers. Properly planted in suitable places, these will give unfailing delight for many years to come.

S. Arnott.

SEASONAL HERBACEOUS BORDERS.

The question of "seasonal herbaceous borders," that is, borders planned to be in full beauty at particular periods, is one that enters largely into garden design at the present day.

Bearing in mind the fact that gardens must be adapted to the needs of the garden-lovers, and that these may be divided into two great groups, namely, those that spend spring and early summer in their country homes and gardens and then migrate to the seaside, and those that remain in town during the London season and turn to the country home during the heats of July. The question is important. This necessitates, on the one hand, herbaceous borders planned to blossom throughout spring until July, and on the other a glow of floral beauty from July until the end of September. Thus it will be my purpose to deal with these two sections separately, and give also a connecting display which shall be suitable for linking the "early" and "late" borders without a break.

I am not in love with "monthly" flower borders, nor with those kaleidoscopic rainbow effects obtained by alternating bright colours with others different but equally bright, a fashion, by the way, which is rapidly dying.

Herbaceous borders should ever be well prepared. Trench well and deeply, and break up the subsoil below. Manure well, keeping this deep enough to be clear of the spade when planting; finally choose, if possible, for planting a time when the ground is dry enough to work well.

For a spring planting, March is undoubtedly the best month, though in forced circumstances I have achieved good results from planting at the end of April. So March let it be, or not later than the first week in April, if a good summer display is to be assured. The reader will bear in mind that exact heights of many herbaceous plants is determined only by the soil and situation of the borders in the district where they are, the variation being great in various districts. Again, varietal forms of many plants differ so much in height and habit (delphiniums, phloxes, Michaelmas daisies being notable cases) that one could not assign exact positions unless acquainted with varieties to be used and ground to be planted.

May and June.

It is not a difficult matter to have a gay border in May and June; it is generally later than this that the border fails to come up to a high standard, but selection will lift the border above the mediocre, and give a character of its own.

The border in May should bear bold defined masses of Darwin and Cottage tulips, of which Clara Butt, Mrs. Moon, King Harold, Claude Gillot, Dream, Pride of Haarlem, Fra Angelico, and many others are wonderfully attractive. In the intervening spaces should spring a wealth of gold and orange trollius, of which Orange Globe, europæus, asiaticus, Fortunei fl. pl., and Newry Giant are worthy of note. Aquilegias are dainty contrast plants, especially the fine long-spurred strains derived from A. cærulea, A. Skinneri, and A. californica, and I must confess to a love of the old English short spurred forms.

Pyrethrums, both single and double, may be utilised. Choose the colours well, pure whites, clear pinks, brilliant scarlets, and rich burnished crimsons are very well. Avoid washy hues, and plant singles in preference to heavy doubles. English, Spanish, German, and other irises should be planted, particularly Germanica varieteis. Here again selection will tell; Edouard Michel, Amas, pallida dalmatica, asiaticus, aurea, flavescens, Maori King, Madame Chereau, and Purple King are among the best. Auriculas, primulas in variety, iberis like corræfolia and superba, saxifrages like Wallacei, ceratophylla, and umbrosa, with masses of Arabis albida fl. pl., and Alyssum saxatile, can be used in the foreground, though if a continuous floral edging be required there is nothing to surpass the best violas.

Doronicums, especially excelsum, Ranunculus aconitifolius plenus, polemoniums in variety, foxgloves, Linum arboreum, L. narbonense, and L. perenne, Dianthus multiflorus, and the floriferous Erigeron speciosum, and its pretty variety Quakeress, assist in filling between bolder subjects.

To continue through June we may bring in Romneya Coulteri, spiræas, and early astilbes, heucheras in variety,the exquisite forms of Pæonia albiflora, Madonna and Orange lilies, and Asphodel lutea, with its yellow spikes, while the glowing Oriental poppies, Prince of Orange, Mrs. Marsh, Lady Roscoe, Beauty of Livermere, and Fringed Beauty are very telling. Eremurus himalaicus, E. robustus, E. Elwesianus, E. Bungei, E. Shelford, and other forms are grand, and these, with thalictrums and delphiniums are fine background subjects. Delphiniums are so good nowadays that a selection is difficult; Persimmon and Belladonna semiplena one must grow, but Rev. E. Lascelles, Lizzie van Veen, Sir Trevor Lawrence, King of Delphiniums, Capri hybrida, and a good white (Nulli Secundus, or something akin to it) will give the basis for a good collection. Incarvillea Delavayi should also be chosen, but I. grandiflora is hardly tall enough for the borders.

With the foregoing one is safe in early summer, the species and varieties named assuring one of a first-rate May-June combination.

Now for the "connective period," which will link up the early and late borders, and carry the whole succession forward without a break.

Connecting Flowers.

Among these connecting flowers we note Verbascum olympicum, V. Choixi, V. Caledonia, etc.; lupins give some fine colours in the polyphyllus group; Chrysanthemum maximum, including Mrs. Lowthian Bell, King Edward, Robinsoni, etc., are fine Gaura Lindheimeri is an unforgettable beauty. Anchusa Dropmore and A. Opal, Japanese irises, Achillea The Pearl, centaureas in many kinds, Gaillardia grandiflora, and Scabiosa caucasica are all good, the latter continuous until the frost. Hemerocallis flava, H. aureole, H. apricot, and H. Dr. Regel, Campanula lactiflora, C. persicifolia, C. macrantha, C. grandis, and C. amabilis are all good,while carnations in approved varieties, Lychnis chalcedonica and many others prove the possibility of continuous beauty.

July to September.

From July to October will be a period of abundant blossom if the selected groups are planted. The main features should be lilies of the speciosum and tigrinum sections, Phlox decussata, such as Coquelicot, Etna, Chardonneret, Pantheon, Helene Vasçeresco, and many others which provide good colouring; montbretias, including the Westwick varieties, and Messidor, Germanica, Vulcan, etc.; tritomas, especially John Benary, R. Wilson Ker, Beacon, Redcap, Cloris, and Lemon Queen. Gladiolus of the primulinus, Childsi, and gandavensis sections are needed, with Lobelia cardinalis, L. fulgens, and L. Nansenciana. Chrysanthemums of the best early florists' forms and helianthuses, omitting the ultra tall forms, must be utilised as well as those ever delightful beauties, the Michaelmas daisies. Of the latter a fair selection would be St. Egwin, Climax, Photograph, Ericoides, Coombe Fishacre, Freedom, Edwin Beckett, Daisy Peters, and the best Amellus varieties.

Pentstemons should be included in all plantings, particularly those of the Newbury "Gem" class, and other first-rate subjects are anemones of the Japonica group, Eryngium amethystinum, E. Oliverianum, and E. giganteum, Linaria dalmatica, and L. repens, Gypsophila paniculata plena, Monarda Cambridge Scarlet, and solidagos like radiata, Golden Wings, and Buckleyi. Echinops Ritro and E. sphærocephalus and Crinums Powelli and Powelli alba must not be omitted.

Furthermore, I would urge the claims (if one has the space for planting) of Artemisia lactiflora, Stenanthium robustum, Aconitum autumnale, A. Wilsoni, and A. Fischeri, Cimicifuga simplex, and C. racemosa, Vernonia arkansana, veronicas in variety, but especially V. subsessilis and V. exaltata, Statice latifolia, S. tartarica, and S. Limonium, heleniums and rudbeckias in a blaze of gold, and the glowing alstrœmerias, of which aurea and aurantiaca are the hardiest.

Lack of space has excluded notes upon arrangement, but in this one must be guided either by one's own particular taste in floral beauty, or else emphasise a few particularly telling subjects in bold groups, and let the more delicate and lighter-growing plants frame the more attractive beauties. Group lightly but freely.

A sufficiency of the first two colours will form a sterling feature, with other shades secondary. Above all, keep the hoe going. A stirred surface gains much both from sun and shower, and with the removal of faded blossoms and timely and careful staking will go far toward securing a fine display of blossom over a long period.

P. S. Hayward.

Parsley.—Make an important sowing to furnish a good supply of plants. On many soils parsley causes anxiety in keeping up a continuous supply, and it is well to err on the side of plenty. Select a sweet soil, and incorporate plenty of wood ashes or soot with it. Parsley lends itself to transplantation; in fact, invariably does better, if planted on a rich piece of ground when the plants are small. Should any sowings have been made in boxes early plantings may forthwith be made of the young plants outside.—C. F.

SIMPLE WATER GARDENS.

The season for nymphæa planting is fast approaching, and those who contemplate making a pool for the culture of aquatics, or already possess a collection and wish to add new varieties or replant some of the old-established clumps which have become overgrown, should lose no time in making preparations, for, although nymphæas may be safely planted from the latter end of April until the beginning of July, the earlier this operation is performed the better, as those planted at the earliest time mentioned will give a good supply of flowers during the coming season, whereas if planting is deferred until a later period, and we experience a cold, sunless season, so that the plants have not the time to make sufficient roots and become established, they may die during the winter.

Another thing to guard against in the planting of new nymphæas, is not to place them in too great a depth of water to commence with; if a weak plant is placed under the surface to the depth of say two or three feet, it will die. Far better to first start it in shallow water,and when it has made sufficient growth it may readily be pushed out into deeper water. Certainly all the hardy nymphæas may be grown in shallow water, but in no case with less than nine inches of water above them, and will flower freely, the only difference in the stronger growing varieties is that the flowers will be somewhat smaller; therefore, by placing them in deeper water they will produce flowers larger and of greater substance.

In the planting of nymphæas I should never advocate a greater depth of water than four feet, although I am well aware our common British water lily, Nymphæa alba, and some of the stronger growing Marliac hybrids and others will flourish in water to a depth of eight to ten feet, and perhaps more. Nymphæas should not be planted so far out in a lake or pond that their beauty cannot be thoroughly enjoyed from the margin, and in no greater depth of water than will admit of their being reached and examined by wearing long fishing boots or waders coming well up underneath the arms. Nor must it be supposed that once nymphæas are planted there they are to remain for years, without any further attention bestowed upon them; they require to be attended to just as much as the plants in our herbaceous borders. Water weeds must not be allowed to grow up and choke them; dead flowers and foliage should be removed occasionally. Sometimes greenfly will be found troublesome on flowers and foliage, and this may be kept in check by spraying with weak insecticide or dusting over with tobacco powder. Again, after growing for some years some varieties increase rapidly and become so crowded that the foliage completely hides the flowers: the Marliacea section require most attention in this respect, therefore it is advisable to raise and divide the plants every sixth or seventh year after planting. On the other hand, some kinds may remain in the same place for years without increasing, but with no loss of vigour or bloom.

As I have previously stated the time for planting nymphæas, and as I only purpose dealing with small pools, and suitable varieties for such, the next consideration will be soil, planting, and plants. Soil for the cultivation of nymphæas should, if possible, be such as can be obtained from the bottom of a natural pond or lake; failing this, a mixture of old loam, the older the better, as I have frequently noticed nymphæa roots do not thrive in fresh loam alone; with the loam mix plenty of half-decayed leaves, road grit, and a little coarse sand or gravel. The use of manure in any form is not advisable, as it only excites rank leaf growth, and predisposes to disease. Where it is possible to drain off the water, small mounds, about nine to ten inches in depth, and two feet or more across, may be made up on the bottom of the pool, laying a few turves round the mound to keep the soil from washing away. When complete place a nymphæa in the centre of each mound, make moderately firm and finish off with a few shingles on top. Just cover the plants with water for the first few days, afterwards adding water gradually until the pool is full.

Where it is not possible to drain the water off, shallow baskets or rounds will have to be employed; these may be eight or nine inches deep, and large enough to accommodate the roots of a plant. Place the nymphæa in the basket in the same manner as if potting any ordinary plant, finishing off the surface with a few shingles, then carry them out and sink them in position in the pool, where, after some time the basket will rot away and the plant become firmly established. Once planted the wants of nymphæas are few; keep the pool as nearly and steadily full of water as possible, and, if it can be arranged to keep the water perpetually fresh, either by stream or jet laid on, this will be found by far the most successful way to good culture. Should scum or any fungoid pest be found troublesome, this may readily be kept in check by occasionally using Bordeaux mixture, which will not injure fish or nymphæas.

[Photo: C. P. Raffill.

THE LILY POOL AT KEW.

From the following list those who contemplate planting a small or medium-sized pool can make a good selection. N. virginalis, of recent introduction, bearing large, pure white, scented flowers; N. Caroliniana nivea, another beautiful white variety; N. pygmæa alba, free-flowering and one of the best for shallow water; and N. odorata minor, another excellent white variety for limited space. Among rose coloured varieties N. Caroliniana, N. Caroliniana perfecta, N. odorata rosea and N. Rosita will be found some of the best. N. atropurpurea, bearing large flowers of a most intense brilliant crimson, with golden yellow stamens; N. William Falconer, also deep crimson; N. Escarboucle, a new variety with very bright vermilion-coloured flowers; N. sanguinea, rich glistening crimson; N. marliacea ignea, also a crimson-flowered variety; and N. Ellisiana, rich currant red, are all excellent. Of the Laydekeri section, which are all suitable for shallow water, N. Laydekeri fulgens, with amaranth-red flowers; N. Laydekeri purpurata, having flowers of a rich rosy crimson, deepening in colour towards the centre, and N. Laydekeri rosea, a fragrant and very profuse bloomer, will be found among the best. N. Brakeleyi rosea, is a free-blooming hybrid of great merit, bearing glistening pink flowers that are very fragrant. Yellow flowering lilies for medium-sized pools are by no means plentiful. Two of the best will be found in N. Mooreana, and N. pygmæa Helvola, the former an introduction from New Zealand bearing flowers not quite so large as the well-known N. marliacea chromatella, but more refined and deeper in colour. N. p. Helvola is one of the smallest of nymphæas, and a gem for tubs or small pools; it has dainty bronzy marbled foliage, and abundance of sulphur-coloured flowers. To those who contemplate planting a small pond, the foregoing list will give ample varieties to make a selection from, and should one part of a pond be somewhat shady, a very delightful plant to introduce would be Aponogeton distachyon, the Cape pond weed, or Water Hawthorn. Although coming to us from such a warm climate it is quite hardy in this country, and if planted in not less than eighteen inches of water it will produce its fragrant white blossoms with jet-black anthers, even well into the dark and dull days of winter.

A. **Bedford.**

IRIS BUCHARICA.

This is a very beautiful species, and a most valuable one for the garden. It belongs to the Orchioides group, and flowers in April. It requires a warm, sunny aspect in well-drained soil, so that the bulbs may be thoroughly ripened during the summer months, when growth has ceased. A hand-light placed over the group during late summer and autumn is beneficial, as the perfect ripening this ensures is essential to the production of good spikes of bloom the following season. Growth commences to show itself early in the year, and should be protected against severe frosts with a little dry bracken lightly laid over the clump; this will prove quite sufficient to prevent any damage being done.

E. C. **Pooley.**

BULBS.—A practical treatise on the cultivation of hardy, hothouse and greenhouse bulbous and tuberous rooted plants is "Bulbs and their Cultivation," by T. W. Sanders, price 2s. 6d. net, or by post 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

HERBACEOUS PHLOXES.

Among herbaceous plants there are few, if any, that provide our gardens with such a wealth of blossom during summer and autumn as the herbaceous phloxes. Such a marked improvement has been made by raisers during recent years that the individual blooms are twice the size of the older varieties, the truss or spike has been considerably enlarged, and the extensive range of colours embraces almost every imaginable shade. There is no doubt whatever as to their popularity, for one rarely finds a cottage garden without its clump of phlox.

These phloxes are divided into two sections, suffruticosa and decussata, the former flowering in June and July, followed by the latter, which prolongs the flowering season into late October. The varieties of the suffruticosa group vary in height from eighteen inches to two feet, while the decussata varieties range from one to four feet. Thus the two classes provide a magnificent display for a considerable period.

A GROUP OF HERBACEOUS PHLOXES, REGENT'S PARK.

Culture.

Cultivation is very easy and simple, for the phlox will adapt itself to almost any position, yet liberal treatment is necessary to obtain the best results. A good depth of stiff loam is the most suitable soil, and this should be trenched and enriched with well decayed manure. The phlox is naturally a gross feeder, and it is essential that the soil should be thoroughly prepared. During dry periods, when the plants are making growth, abundance of water must be given, and mulching proves beneficial as it prevents the rapid evaporation of moisture, and keeps the roots cool. This is especially necessary in dealing with dry soils. The early flowering varieties suffer from the effects of the hot sun, and the flowers quickly wither if the plants are allowed to become dry at the roots. Undoubtedly a cool border is preferable to a hot one, yet one has to meet the case in various ways, and endeavour to remedy whatever evil is likely to occur when a dry border has to be utilised for the purpose of growing them.

Boldly grouping each variety separately is the most effective plan, taking into consideration the colour scheme, so that one colour does not clash with its neighbour. Of course the size of the groups must be governed by the width of the border. When this is twenty feet wide the groups should be larger than when one has only about a six-feet wide border to deal with. The order of the present day is massing, and rightly so, for the beauty of the plants can be more appreciated thus than when they are dotted about singly.

Planting may be done any time from the end of October until March, during mild weather. Autumn planting is preferable as the plants stand a better chance of becoming established before the dry weather sets in. When the planting is deferred until spring more soil should be allowed to remain on the roots, and the clumps must not be pulled about so much as in autumn. The plants should be put out at least two feet apart, to allow the growths sufficient space to develop properly. No benefit is gained by overcrowding, and it is necessary to reduce the number of shoots if the clumps are strong. This operation may be performed in March, when the growths are a few inches high. From six to nine shoots are ample.

Phloxes should not remain undisturbed for more than three years; at the end of this time they will require lifting and dividing. This will allow the ground to be trenched up again, and enriched with manure before replanting. When dividing large clumps the woody centres should be split with a fork, when they may be easily pulled apart with the hand. By no means should a spade be used for the operation, or a great many shoots will be sacrificed.

Propagation.

There are three ways by which this may be carried out, viz.: seeds, cuttings and division of roots, the latter being the most simple. The shoots which are removed during March when thinning provide good cuttings, and should be inserted in pots filled with sandy soil. These root freely in a little heat, and will provide a late supply of bloom, for usually each shoot will flower the same season. When rooted the cuttings should be potted up singly and grown in a cold frame, eventually planting them out, in well prepared soil. Seeds may be sown in March or April, in pans or boxes, and placed in a cold frame, shading them to prevent too rapid evaporation. When the seedlings are large enough to handle they should be transplanted into a frame and kept growing until they are large enough to plant out into nursery beds.

Varieties.

The following will be found to provide a good representative collection: Suffruticosa varieties (early flowering)—Mrs. McClellan, Snowdon, Mrs. Miller, Dr. Hornby, A McKinnon. Decussata varieties, flowering August to October—whites: Tapis Blanc, Mrs. E. H. Jenkins, Henri Murger, and Rheingau. Purple shades: Eclaireur, Le Mahdi, Edmond Rostrand and Reichsgraf von Hochberg. Salmon and scarlet shades: Coquelicot, Etna, Pantheon, George A. Strohlein, and Moliere. Blue and lilac shades: Eugene Danzanvilliers, Pharaon, Esclarmonde, and Iris. Pink and rose: Parthenon, Charles Pfister, Lady de Ramsay, Sergent Lovy, Mrs. Oliver, William Robinson, and Gruppen Konigen.

SASH BARS.—Special lines in certain lengths only, 1¼ by 1, 2s. 6d. 100ft.; 3 by 1¼, 5s. 9d. 100ft.; quotations for special lengths or for any kind of timber, garden lights, greenhouses, and woodwork. C. JENNINGS and CO., Timber Merchants, General Woodworkers, 916, Pennywell Road, Bristol.

BEDDING VIOLAS.

It is advisable in these latter days to always clearly define the purpose violas are intended for, or one may plant out popular varieties that are suitable for exhibition purposes, but which present a sorry display as bedding plants, though they may be very beautiful as individuals.

I take it a bedding variety should be first of all very free flowering, should have a well-defined colour, and last, but not least, should possess a good habit and constitution. All these points, however, are not so easily found in a single variety as one would imagine, for frequently a fine sort, so far as colour and freedom are concerned, has a straggling habit of growth which is very much against its appearance in a mass, although the variety may be useful in other directions. The best method of judging the merits or otherwise of violas is to plant beds of each variety side by side, as one usually does in the case of trials, or on the stock beds at a nursery; then their true habit and effect can be clearly seen.

VIOLAS AS CARPET PLANTS IN ROSE BEDS,
At Hopetoun House, the residence of the Marchioness of Linlithgow.

Colour is, perhaps, the primary consideration, and most violas are planted with the idea of producing some colour scheme. This they do admirably, as their tones, clearly defined as they may be, are soft and pleasing; and if the right colours are selected there is little fear of clashing. The habit of the plant should be dwarf and spreading, so as to cover the entire bed early in the season, while it is a sine quâ non that they should flower unceasingly from May until late in the autumn. Violas have become very popular in large parks and public gardens during the past decade, and no doubt they owe their present-day position largely to this fact. The trade exhibits of violas at our flower shows have not advanced this particular section very much, simply because the nurserymen generally stage the large exhibition sorts, which, in my opinion, give, as a rule, a very poor account of themselves in the garden.

Few plants produce such a fine effect with such a minimum of outlay or trouble as violas, for in most gardens they are perfectly hardy, and pass through severe winters unscathed, but this is not so near large towns, and in smoky, or foggy districts, for in such places the plants must be sheltered in cold frames during the winter months; Here they generally pass safely to the following spring, when they can be put out in their summer quarters. The question of autumn v. spring planting has to be largely settled by local conditions; when the latter period is decided upon, it should be clearly understood that early planting is absolutely necessary if the beds are to prove satisfactory. I should always endeavour to plant out in March or as early as possible in April. This will allow the plants to establish themselves firmly before their flowering season commences. It is surely unreasonable to expect the plants to re-establish themselves and continue to bloom satisfactorily at the same time; yet this often occurs, as, for instance, in May and June planting. Should this be compulsory on the part of the planter then the flowers and buds should be removed for at least a fortnight. After this period they will produce good flowers again, but wherever possible early planting should be the rule.

Elaborate preparation of the soil is unnecessary; if the soil is cultivated well, as for any other crop, that is sufficient, but a firm soil is at all times desirable. Where violas have been growing on the same ground for a number of years, and appear not to be doing well, the addition of a good dressing of loam will soon remedy the evil, and prove far more effectual than any fertilisers that can be utilised. A change of situation will also produce new life and vigour to the plants, but it is not always possible to give a new position, so in such cases I should always rely on the loam. Needless to add that such fibrous-rooted plants require plenty of moisture, especially during a dry spell. Those varieties that seed freely must have the seed pods clipped off as soon as formed, for if left, the flowers produced afterwards are small and poor. It is wise to cut back the old growth as it shows signs of exhaustion, dealing with just a few plants at a time so as not to disfigure the bed; this keeps up the vigour of the plant by encouraging basal growth, which is quickly produced.

As to varieties, there are plenty to choose from, but the followihg are selected for the points mentioned as being desirable: Whites—Queen of Whites, Swan, and Seagull. Blue: Bridal Morn, pale blue; and Admiral of the Blues, deep blue. Purple: Councillor Waters, deep purple; and J. B. Riding, rosy purple. Yellows: Redbraes Yellow, Mrs. E. A. Cade, and Ardwell Gem, pale yellow. Blush: William Neil, Bessie, and Kitty Bell. Many of the edged or bordered kinds are also employed, such as Duchess of Fife and Goldfinch, but their value for bedding purposes I do not consider so great as that of the self colours.

J. B. Riding.

Lettuce.—Give more air to the young plants in cool frames, with a view of placing them out as soon as the weather is suitable. When sufficiently hardy, they may be planted under a south wall. Also make a sowing in a similar position, to follow on. The cos variety Little Gem is satisfactory to sow for this crop, as it turns in quickly, and is of first rate quality; it also travels well when packed.—C. Flack.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

COOL HOUSE ORCHIDS.—The different species and hybrids will help to make the cool houses brilliant with their flowers from now onwards. A very beautiful effect is produced by the varied tints possessed of the recently raised hybrids, and there is nothing more effective than the odontiodas. The bright colours that are produced by the different crosses between odontoglossums and cochliodas is most remarkable, and they provide a long-needed contrast to the white and rosy-tinted flowers that are characteristic of this division. Now that they have become plentiful, and may be procured at a modest outlay, they should be extensively cultivated, as they are worthy of every consideration where there is a demand for cut flowers or plants for decorative purposes in private gardens.

ODONTIODAS we find grow vigorously when treated under the same conditions as that afforded Odontoglossum crispum. For potting purposes we find they are best attended to at the time the young growths have reached that stage of development when the new roots are emitted from the base; but when dealing with young plants that have not previously bloomed repotting at such a period has a tendency to cause the plants to continue growing instead of flowering as soon as the pseudo-bulb has reached maturity, and a season is thus lost in determining its varietal character. Therefore, when dealing with unflowered plants that are sufficiently robust to bloom, it is desirable to defer potting until after the pseudo-bulb has matured and passed out of flower. As soon as the flower scapes have been removed potting must be attended to without delay.

POTTING.—The plants should be carefully turned out of their pots so as to avoid damage to the active roots which may have penetrated to the outside of the potting compost. If the old material is in an advanced state of decay it must be carefully picked away from among the roots, or even washed away in a pail of tepid water, but if it is in a reasonable state of preservation, then remove any decaying matter on the surface, and give the plant more root room without disturbing it more than is absolutely necessary. We find that no compost meets the requirements of the cool-house orchids better than two parts fibrous peat and one part of sphagnum moss and broken oak or beech leaves. The leaves should be sterilised before use to destroy any fungoid or insect pests. This compost is made moderately firm. The pots are drained to about one-third their depths with chopped bracken roots or broken crocks. As soon as repotting is completed water with rain water, taking care to wet the compost through. Shade the plants carefully from bright light for a few weeks after repotting, and keep the atmosphere in a humid state. Lightly spray overhead in the afternoon after warm days.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CHRYSANTHEMUMS.—Plants intended for the production of large blooms must have due attention given to potting to keep them steadily growing. After potting, replace them in a cold frame, and keep them rather close for a day or two, afterwards increasing the amount of air gradually until they can be fully exposed to sun and air. Syringe the plants when the weather is favourable, and water with care. Keep down insect pests by occasional syringings with insecticide. Plants of the "bush," or decorative type should have the points of growth removed when about six inches high to induce them to break, but this must be done a week before or after potting.

PRIMULAS.—Sow seeds in well-drained pans of fine loam, leaf-soil, and sand. After the seeds are sown cover the pans with glass, on the top of which a sheet of brown paper should be placed. As soon as the seeds have germinated remove the coverings. When the seedlings have become used to the light place them on a shelf near the glass, and shade from hot sunshine. When large enough to handle the seedlings may be potted singly in small thumbs, or pricked out in boxes, from which they may be transferred to 60's. A temperature of 50 degrees is sufficient for raising primulas.

CELOSIAS AND BALSAMS should also be sown now. In the case of the former it is advisable to make a few small sowings at intervals rather than one large one, so that they may be had in flower in succession.

CANTERBURY BELLS.—A batch of the plants which have been plunged outside or in frames during the winter may now be brought inside to make an early display.

SCHIZANTHUSES.—These are among the most useful of plants for decoration, giving, as they do, such a delightful variety of colours. They are of easy culture, requiring no heat, but merely protection from frost. By sowing at intervals schizanthuses may be had in flower the greater part of the year. Except when small seedlings, or when repotted, they should be afforded all the sun and light possible. Those most suitable for conservatory decoration are S. Wisetonensis and S. pinnatus.

FORCED PLANTS. — Rhododendrons, azaleas, and other hard-wooded plants which have been forced, and are wanted for another season, should have their seed pods removed, and be placed in a warm house, where they may receive frequent syringings to induce new growths. Attention must be paid to any that require repotting, as this should be done before the new growth is far advanced.

THE CONSERVATORY. — The flowering plants now furnishing the conservatory are mostly forced ones, so that partial shading should be afforded during hot sunshine. Ventilate the house carefully to prevent sudden changes in the temperature caused by the changeable weather usually experienced at this time of the year.—A. Grubb, Porter's Park Gardens.

HARDY FRUITS.

GRAFTING.—This interesting and progressive work may be proceeded with as soon as the bark runs freely. Old and unfruitful trees of apples and pears may, in the course of three or four years, be made to carry crops of fine fruit if grafted with good vigorous reliable varieties. Much of the success of grafting depends on the constitution of the scions used, much more so than the vigour of the stock, and this is very noticeable on looking through an orchard of mixed varieties of apples. It is surprising how soon the head of a strong-growing apple will develop the stock, and, naturally, the root action must develop accordingly. Such apples as Bramley's Seedling, Newton Wonder, Worcester Pearmain, James Grieve, and Wealthy I find succeed, and give extra-fine fruit; pears, such as Triomphe de Vienne, Margaret Marillat, and Doyenne du Comice, do well, the latter giving very fine fruit and cropping regularly.

DIFFERENT MODES OF GRAFTING.—There are various ways of grafting, but the most simple for large trees, and a very satisfactory one, is crown or rind grafting. The scion is cut obliquely, but a shoulder is made at the base to rest on the top of the stock. The bark of the stock should be slit down about 1½ inches, and if the sap is running freely, the scion (which should not be too large, but the wood firm and green), if given a slight start at the top, may be forced home freely and rapidly; give a firm tie with raffia as near the top of the stock as possible, adding the wax or clay.

GRAFTING WAX OR PUG.—Where it is the intention of the grower to graft a lot of trees time will be saved by using grafting wax, which may be easily home made, but if only a few trees are to be manipulated a good "pug" may be made by mixing clay, loam, and cow manure, in about equal parts, into a thick paste, adding enough chopped hay, about an inch long, to toughen it; the hands should be dipped in water each time before forming the cone of pug round the graft.

AFTER MANAGEMENT.—Standard trees, if much exposed, will require a little care as the growth advances, or much damage will be caused by rough winds blowing the growths clean away from the stock; this will often happen towards the end of the summer, and may be avoided by fixing stakes, about three feet in length, giving two ties to the stock and one to the graft.

PROTECTION.—Protection to wall fruits should now be afforded. This is not a difficult task where glass or wood copings and curtains are provided, but where netting and other makeshift materials have to be requisitioned great care must be exercised, or more harm than good may result, netting having the unfortunate knack of damaging the buds, therefore it should be kept well away from the trees. A double thickness of netting at least will be required to protect the blossoms, and this should not be put up in long stretches, or a draught will be set up along the wall, and will cause leaf blister to peaches, and an unkind condition to the blossom of all fruits.—J. Whittle, Cheveney Gardens.

THE KITCHEN GARDEN.

PEAS.—Harden off the pot-sown peas to full exposure to have them in condition for planting out. The part of the country and condition of the weather should be taken into consideration, but, speaking generally, it will from now be safe to plant them on a warm border. It is advisable to place the sticks to them at the time of planting for the purpose of affording protection, and should sharp cutting winds occur give further shelter by placing spruce or laurel boughs on each side of the rows. A sowing of main crop varieties may also be made to give a succession to those June pickings. Choose an open position, and soil that has been trenched or deeply dug and is in a rich condition. Sutton's Prizewinner, Fertility, and the Duchess are peas of excellent quality, and suitable for this sowing. For further sowings, trenches, where possible, should be made ready. The extra amount of labour is well repaid, as the crops can be more effectually managed, especially at times when the rainfall is light.

CARROTS.—Where the soil is of a light porous character the main crop of carrots may be sown now. A dressing of wood ashes or soot is very helpful if worked in on the surface of the ground when the seed bed is being prepared by forking and raking it down to a fine tilth. Heavy land is usually more or less difficult, and should not be taken in hand until sufficiently dry to crumble down finely. In any case land for this crop is to be preferred that has been laid up to the weather during the winter months. Draw the drills at about fifteen inches apart. A good type of Scarlet Intermediate is the best for this sowing. For rough culinary purposes the old Long Red Surrey gives a heavy yield.

FRENCH BEANS.—If a warm pit with a circulation of hot water running round it is at command, make a good sowing to succeed the pot-sown crop. A rich open soil is essential for a good return. Sow the seed in drills not nearer than 2ft. apart. When the young plants appear grow them sturdily in a humid atmosphere. If properly managed, this will prove a valuable crop before the earliest peas are in. Canadian Wonder and Fulmer's Forcing are both free varieties under this system of culture.

GENERAL REMARKS.—If a suitable site is available for celery, proceed with the making of the trenches. Make further plantations of potatoes during the next few weeks in suitable situations. Lift herbs, such as tarragon, mint, and chervil, and place as required in the forcing house. Stocks of pea and bean sticks should be at hand now to give employment to the staff on wet days.—C. Flack, Cholmondeley Castle Gardens.

OBITUARY.

MR. JAMES GEORGE.

Born at Faringdon, Berks, in 1826, Mr. James George, who died at Putney on Friday, March 10, had lived and worked among horticulturists all his long life, and was as highly respected as he was widely known. His father had a nursery business at Faringdon, where many of the old florists' flowers were cultivated, and where Mr. J. George early became interested in dahlias, pansies, and pelargoniums. After school days and a short sojourn in the home nursery Mr. George was apprenticed to Mr. G. Milne, at Faringdon House, and before he had attained his majority he was appointed head gardener to Lady Warnford, Warnford House, Sevenhampton, Wilts. Here he stayed four years, and then filled a similar position at Lee for two years. Through the aid of the brothers Fraser, of Lea Bridge, Mr. George became head gardener to Miss Nicholson, at Stamford Hill, and here he continued for fourteen years, moving with his employers to Putney Heath, and there serving a further period of sixteen years with the same family. It is to Mr. George we owe the race of dwarf tropæolums, which he raised by a process of selection from the tall kinds. He entered heartily into the work of raising zonal pelargoniums, and in 1872 he won first prize for eighteen and for twelve plants with his own seedlings, in a contest where the flowers were tested by florists' rules; he also secured four First Class Certificates on this occasion. Mr. George, in later years, took abutilons in hand, and by 1883 he was supposed to have the finest collection of these flowers known. Mr. George was one of the oldest of the members of the National Chrysanthemum Society, and he was a foremost prizewinner in the old Stoke Newington days. He was also one of the founders of the United Horticultural Benefit and Provident Society, and was awarded a handsome timepiece for the efficient help he rendered by sending flowers and plants to the exhibition held at the Guildhall (chiefly under the direction of Mr. William Marshall, V.M.H., and the late Mr. Shirley Hibberd), the result of which was £300, wherewith to place the society in a sound financial position to begin with.

THE LATE MR. J. GEORGE.

In later life Mr. George commenced business as a horticultural sundriesman at Putney, and the business will now be continued by his two sons. He was, to all intents and purposes, the inventor of tobacco paper for fumigating, and he carried on a big trade in this material until vaporising became well known and adopted. Mushroom spawn, soils, and manures were special lines of his business, and wood wool for packing fruits, etc., was first brought into notice by Mr. George. Full of years and honour, Mr. James George was laid to rest in Putney Vale Cemetery on Thursday, March 16.

GLADIOLI AND MONTBRETIAS.

These two families of flowers include some of the most beautiful and charming late-flowering outdoor subjects. The ease with which they can be grown, both as regards soil and situation, their value as cut flowers, and as objects for garden ornamentation during the late summer and autumn, render them indispensable, and insure for them a place in every garden. There are numerous varieties of each, all quite dissimilar, and yet in certain respects they bear a striking resemblance.

Gladioli.

Although they are both practically hardy it is necessary to lift the corms in the autumn and replant them in the spring to secure the best results, and this is especially so with gladioli, as they will not withstand the winter in some localities. When they are taken up early in November, dry them off and store away in a frost-proof shed for the winter.

Gladioli are divided into several groups, and to take the early flowering section first we have amongst them some lovely varieties which commence to bloom at the end of June in the open garden. The best time to plant is in March, although in exceptionally warm districts they may be put out during February. To obtain the most pleasing results they should be planted in a border set apart for them, or failing this, they can be planted in groups of one variety in the ordinary mixed flower borders; to be really effective there should be about seven in each group. They succeed best in a medium loam that has been well cultivated and suitably enriched with manure. Plant with a trowel, about four inches deep, and place a little leaf-soil around the corms before replacing the ordinary compost. A space of about six inches should be left between each, but this may be varied according to the vigour of the variety. Such varieties as The Bride, Peach Blossom, Fire King, Mauve Beauty, and Queen of Holland (a white form with rose coloured flakes), are some of the most showy of this section.

In the bedding or Gandavensis group there are many very fine varieties, producing handsome erect spikes of bloom until late autumn. Whole beds can be filled with them if so desired, and where a brilliant show of bloom is required in the autumn they would be hard to surpass. Planted in groups in the front of shrubberies they are very effective, the background of green setting them off to advantage. Eclipse is a lovely white variety; Walmer, rosy scarlet; Lord Byron, a brilliant carmine, with white blotch; Marshal Oyama, rich crimson; and Magnificent a lovely salmon rose. Among the newer varieties, America, a soft lavender-pink, is wonderfully telling, and an altogether very pleasing shade of colour. Princeps is a fine deep scarlet, with a creamy white throat, and Baron Joseph Hulot a very distinct flower that might be described as violet, shaded blue. Selected seedlings, such as are supplied by the leading firms, are of much value for the production of rich displays of colour, and as the corms are moderate in price they should be freely planted.

Montbretias.

There is some difference of opinion as to whether montbretias should be transplanted annually or not. To obtain good flowers, however, it is certainly desirable to transplant pretty frequently, for when clumps remain undisturbed for a considerable length of time they make a quantity of small corms, produce an excessive amount of foliage, and only a few flowers of poor quality; this is especially the case in light sandy soils. Moreover, in some districts montbretias do not always survive the winter, so that in the case of those growing in the ordinary flower borders it is a good policy to lift them annually where the soil is excessively wet and heavy. When lifted they should be tied up in bunches and stored for the winter in a similar place to that recommended for gladioli.

Planted in the herbaceous borders associated with white Japanese anemones, montbretias are very effective, and prolong the display of bloom until frosts come. Growing on the outskirts of shrubberies, near woodland walks, or naturalised in the wild garden, they are very telling, and add a touch of colour to the surrounding beauties of nature. They also look well associated with some of the fine-leaved bamboos when planted as a margin to their beds. The finest varieties are very striking and command attention amongst the most handsome of perennials. Prometheus is one of the best, and is a very vigorous grower with brilliant, rich orange flowers, flushed with crimson at the centre, and they are freely produced on tall, erect stems. Lady Hamilton is a striking variety with a yellow centre, suffused with apricot when fully expanded. Norvic, a distinct plant of rather dwarf growth is late flowering, and has a yellow flower stained with red. Germania is a handsome free-flowering variety, with rich scarlet blooms shading to brilliant orange, and a dark red throat. Koh-i-noor is a pure orange bloom with apricot base. Oriflamme is large, orange scarlet, and George Davidson, an intense golden yellow, is very free-flowering.

FALMOUTH SPRING FLOWER SHOW.
THE SHOW OF THE CORNISH RIVIERA.
To be held April 19th and 20th.
To be opened by their Royal Highnesses Prince and Princess Alexander of Teck.
First-class Band and Programme.
Free accommodation to the Trade.
Schedules and full particulars,
R. E. GILL,
Hon. Secretary,
Falmouth.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

North of England Horticultural Society.

Wednesday, March 22, 1911, will be long remembered as a day of great interest, historically, in the horticultural world, and, if hopes are fulfilled, the day will become an important one, for on this date the North of England Horticultural Society held its first exhibition and lecture.

A great deal has been said, and a very great deal written, concerning this new venture, and many fears have been expressed and many hopes entertained as to its success. Much spade work has had to be done, so that the foundations of a successful horticultural society for the North of England might be well and truly laid. The lines followed by these northern enthusiasts are a modification of those that have proved so successful in connection with the Royal Horticultural Society. An ambitious programme has been outlined, including the institution of standing committees to adjudicate upon orchids, flowers, fruits, and vegetables, and to discuss scientific matters, so far as these apply to horticulture. In addition to monthly exhibitions and lectures, a "Magazine," is proposed, and an unusual item in it will be reviews of the regular horticultural weeklies, one page to each journal.

As regards its personnel, the North of England Horticultural Society makes an excellent start, and in its secretary, the Rev. J. Bernard Hall, has one of the most hard-working and enthusiastic men it has been our lot to meet. He possesses organising ability of no mean order, and an enthusiastic optimism that will overcome many difficulties, and be not easily turned aside from the great ideal set before him, i.e., the establishment of a great, strong, permanent, and useful horticultural society for the northern part of England. The Council, with Major J. W. Dent, Ribston Hall, Wetherby, as chairman, and the Hon. Rupert Beckett as treasurer, are going ahead. Mr. Jessop, one of the moving spirits, is to be chairman of the Orchid Committee, and Mr. Martin is chairman of the Floral Committee.

There was not a big attendance, and doubtless there were many absentees owing to the funeral of one of Leeds greatest public men—Lord Airedale—the same day.

Fellows of the R.H.S. may become Fellows of the North of England Horticultural Society at half fees, i.e., 10s. 6d., and arrangements have been made for members of the several R.H.S. standing committees to occupy a seat on the corresponding committee at Leeds when visiting the latter city, and, we may add, from experience, that a very hearty welcome will be extended to all such members.

The exhibition was held in the Emannuel Hall, Leeds, close to the University, and the roomy hall was well filled with exhibits, and there was a goodly and a bright display that promised well for the future, and reminded us of the meeting of the R.H.S. in the early Drill Hall days. The awards of medals, etc., were made with considerable care, and there was not the slightest wish on the part of anyone concerned to make these awards cheap. Everyone was in excellent good humour, the exhibitors were asked to meet late in the afternoon and make suggestions for the conduct of future shows, every officer and committeeman was courtesy personified, and the horticultural press men were treated with a kindness and hospitality that was at once unusual, and very highly appreciated.

During the afternoon the Rev. J. Bernard Hall announced that 120 Fellows and 20 Associates had paid subscriptions, and he thought that if all who had promised to join paid in within a month there would be a thousand Fellows. He suggested that the August show would be held at Harrogate, and on that occasion the R.H.S. was going to send down a deputation to award medals, etc. The autumn show, on November 15, would be held at Newcastle. The society had no intention of becoming a purely local effort. He thanked the exhibitors who had come forward on this occasion, and also the R.H.S. Fellows, who had come to their assistance, and he said that Mr. Gurney Wilson, of Haywards Heath, had promised to act as secretary of the Orchid Committee.

The lecture, held at the University in the evening, was well attended, and there was a very attentive audience to hear Dr. E. J. Russell, of Rothamsted, give his lecture on "Soil Germs and Plant Food." In connection with this lecture a word of thanks in due to Professor Seton, of the University, for very many kindnesses.

FLORAL COMMITTEE.

Messrs. Robert P. Ker and Sons, Liverpool, presented a glorious lot of amaryllis, all finely grown, and representing a remarkably beautiful strain, the result of long years of cross-breeding and selection and high cultivation. The Messrs. Ker have made a great name for their amaryllis or hippeastrums, at home and abroad, and they admirably sustained that reputation on this occasion. The plants carried good spikes, and in some cases there were as many as three spikes from one bulb. The deep crimson varieties like Ajax, Ruby Perfection, Midnight, and Imperial; Ruby King was well named, while Admiral Togo was another fine ruby-coloured variety; and Magenta Queen, Iona, Carminata, Queen of the Netherlands, Princess Ida, and Daybreak were all delightful varieties with magenta, rose or pink shading. Moonlight, Albescens, Andromeda, Silver King, and Fimette, were all nearly white, and they served in admirable fashion to show up the more brilliant members of the group.

Messrs. Wm. Cutbush and Son, Highgate, N., filled one side of the hall with a very interesting display. The major portion consisted of hardy flowers and shrubs, all brought into flower somewhat earlier than their natural season. Here there was a background of bamboos, lilacs, with groups of Ledum compactum, Azalea Yodogama, Andromeda usillaris, Spiræa confusa, Rhododendron Pink Pearl, Magnolia speciosa, and Kalmia glauca, surmounting the rockwork. In the foreground were double and single hepaticas, Tulipa Kaufmanni, Primula denticulata, P. nivalis, Anemone blanda, and Iris bucharica. At one end there were groups of fragrant boronias and Otaheite oranges, and at the other end a fine display of carnations, in which leading varieties, well shown, were Marmion, Lady Elphinstone, Scarlet Glow, Mrs. W. Ward, White Perfection, Admiration, Alma Ward, Lady Coventry, May Day, Mrs. Fortescue, and a new big scarlet perpetual Malmaison variety named King George, a grand variety, as shown, but represented by only one plant.

In front of the platform Messrs. W. Artindale and Son, Nether Green, Sheffield, arranged an undulating group of Primula obconica. The plants were all in the pink of condition, the flowers large, plentiful, and the trusses excellent. Moreover, the colour range was delightful, and some of the rich shades, almost crimson, deservedly attracted a great deal of attention, notwithstanding that at present these deep-hued forms have rather smaller flowers than the lighter coloured varieties of the grandiflora strain yield.

Narcissi and tulips were extensively shown by Messrs. R. H. Bath, Lim., Wisbech, this firm exhibiting a considerable number of tulips grown in fancy bowls in fibre and crushed shell. Among the narcissi leading varieties were Madame de Graaff, the poetaz variety Aspasia (N.D., 2nd), Emperor, Lucifer, Sir Watkin, and Leonie. Tulips included such useful varieties as Village Boy, Rose Gris de Lin, Bartigon, La Reine, Vermilion Brilliant, Yellow Prince, Brunhilde, Queen Wilhelmina, Proserpine, and King Harold. The display was neatly margined with small vases of Chionodoxa Luciliæ and scillas.

The carnation group set up by Messrs. Young and Co., Hatherley, Cheltenham, contained good vases of Rose Pink Enchantress, Marmion, Lady Audley Nield, Britannia, Mrs. H. Burnett, White Perfection, and a handsome new rich crimson perpetual variety named Duchess of Devonshire, and one that promises well.

Robert Sydenham, Lim., Tenby Street, Birmingham, showed excellent bowls of such narcissi as President Harrison, rugilobus, Empress, Madame Plemp, Leonie, and Mrs. Langtry, all grown in moss fibre; a bowl of horse-chestnut seedlings in the same material was a source of great interest.

ORCHID COMMITTEE.

The whole length of one table was occupied by Messrs. Mansell and Hatcher, Rawdon, Leeds, who put up a very interesting and beautiful group of orchids that would have been improved had more of the pots been hidden by ferns. Leading subjects were Odontoglossum loochristiense, O. Adrianæ, O. crispum, O. Manselliæ (N.D. First) from O. Vuylstekæ and O. Harryanum—a striking hybrid, with rich brown-crimson colouring and yellow tips to the segments; O. ardentissimum, O. crispo-Harryanum, Miltonia Bleuana, Brasso-cattleya Mendeli-Digbyana, Dendrobium Brymerianum, Trichopilia suavis, the beautiful Lycaste Mary Gratrix, and a large number of dendrobiums of the nobile and Ainsworthi sections; with a few golden oncidiums enlivening the whole.

Mr. H. A. Inness, Monkend Gardens, Croft Spa, near Darlington, contributed a small collection of odontoglossums, chiefly O. crispum, O. triumphans, Cypripedium aureum, C. Leeanum varieties, C. Chamberlainianum, and C. Io. grande. There were also a few dendrobiums, and the whole made up a pretty group.

A delightful group of orchids set up at the end of the hall by Messrs. Charlesworth and Co., Haywards Heath, had a charming plant of Odontoglossum venilia (pescatorei and cirrhossum) as centrepiece, this carrying two big spikes and scores of elegant flowers. Around this were Phaius Norman, the lovely Brasso-cattleya Queen Alexandra, Odontoglossum eximium, O. Armainvilliersense Xanthotes, O. Warnhamense, O. Adrianæ, Brasso-cattleya Veitchi, Odontioda Bradshawiæ, O. Keighleyensis, O. Lutetia, and O. Charlesworthi, Cypripedium Thompsonianum, C. Lawrebel, and other good things.

Messrs. James Cypher and Sons, Cheltenham, presented a group of orchids, with a fine Cymbidium Lowianum in the centre. Cattleya Mendeli, C. Schroderæ, and C. Trianæ, Odontoglossum crispum, O. triumphans, O. gloriosum, Renanthera Imschootiana, Cypripedium Bridgei magnificum, C. Helen II. Westonbirt var., C. aureum Hyeanum, Sophro-cattleya Wellesleyæ, Dendrobium agregatum majus, and Masdevallia tovarensis were other good things.

Mr. F. Corney, gardener to J. H. Craven, Esq., J.P., Beeches, Keighley, Yorkshire, brought up a group of pretty orchids, in which Odontioda Keighleyensis gloriosa, O. Lutetia, and O. Bradshawæ were especially bright. There was a good assortment of odontoglossums, notably crispum varieties and O. loochristiense, with Cypripedium Euryades, C. aureum, C. Gowerianum magnificum, Lycaste Skinneri alba, Lælia Jongheana, Miltonia Bleuana, and various cattleyas and lælio-cattleyas.

Mr. Alva J. Hall, Parliament Street, Harrogate, showed a few good cypripediums, such as C. aureum G. F. Moore, C. Euryades, C. Goweri, C. Godseffianum, and C. Pitcherianum Williams var.

Mr. Gilchrist, gardener to Wm. Matheson, Esq., Glenburne, Horsforth, presented Odontoglossum Phœbe Glenburne var. (N.D. second)—a handsome plant.

Major Rogerson (gardener, Mr. Price), Harpenden, Herts, sent up Odontoglossum eximium Lily Wilkinson, richly hued (N.D. second), O. xanthotes, and the fine O. crispum Leonard Perfect.

Mr. W. Shackelton, Great Horton, Bradford, showed rosy forms of Odontoglossum crispum.

Messrs. Hassall and Co., Southgate, brought forward a fine Odontoglossum hybrid between O. crispum and O. amabile, O. Dora and Cattleya speciosissima.

Messrs. A. J. Keeling and Sons, Westgate Hill, Bradford, had in their little group of orchids such interesting plants as Dendrobium nobile album, D. Ainsworthi, varieties of Odontoglossum crispum, Cattleya gigas, and a few cypripediums. We suggest that this firm should add to the value of the meetings by labelling their plants, so that the general public could learn their names.

CERTIFICATES.

Northern Diploma, First Class.—To Brasso-cattleya Queen Alexandra, from Messrs. Charlesworth and Co., Haywards Heath; to Odontoglossum Mansellæ, from Messrs. Mansell and Hatcher, Rawdon, Leeds; to Sophro-cattleya Wellesleyæ, from Messrs. Jas. Cypher and Sons, Cheltenham.

Northern Diploma, Second-Class. — To Dendrobium Plumptonense, from Messrs. Mansell and Hatcher, Rawdon; to Lycaste Mary Gratrix (also Cultural Commendation), from Messrs. Mansell and Hatcher; to Odontoglossum eximium Lily Wilkinson, from Major Rogerson, Harpenden; to Odontoglossum Phœbe Glenburne var., from W. Mathieson, Esq., Glenburne, Horsforth; to Cypripedium Bridgei magnificum, from Messrs. Jas. Cypher and Sons, Cheltenham; to Odontioda Keighleyensis gloriosa, from J. H. Craven, Esq., Beeches, Keighley, Yorks; to Narcissus Aspasia, from Messrs. R. H. Bath, Lim., Wisbech; and an azalea, from Messrs. Robert P. Ker and Sons, Aigburth, Liverpool.

MEDALS.

Large Gold.—To Messrs. R. P. Ker and Sons, Liverpool, for amaryllis.

Gold.—To Messrs. Mansell and Hatcher, Rawdon, for orchids; to Messrs. W. Cutbush and Son, Highgate, for carnations and hardy flowers.

Large Silver-Gilt. — To Messrs. Charlesworth and Co., Haywards Heath, for orchids; to Messrs. Jas. Cypher and Son, Cheltenham, for orchids.

Silver-Gilt.—To Messrs. W. Artindale and Sons, Nether Green, Sheffield, for group of Primula obconica; to J. H. Craven, Esq., Keighley, for orchids.

Large Silver.—To Messrs. R. H. Bath, Lim., for narcissi and tulips; and to Mr. H. A. Inness, Croft Spa, Darlington, for orchids.

Silver.—To Messrs. A. J. Keeling and Sons, Bradford, for orchids; and to Messrs. A. Young and Co., Hatherley, for carnations.

Beckenham Horticultural Society.

It must have been highly gratifying to Mr. Horace Wright to face such an audience as attended at the Beckenham Public Hall on Friday, the 17th inst., to hear him discourse on "Sweet Peas." Many friends from the Bromley and Bickley Societies were in the audience, which also included some ladies. Mr. Sherley-Price, one of the vice-presidents, occupied the chair.

National Dahlia Society.

The conference held by this society last year was so successful that another such gathering was quickly arranged for, and the date fixed for March 17. On this date, at Carr's Restaurant, at six o'clock, the meeting was held, under the presidency of Mr. Edward Mawley, V.M.H.

A fair number of dahlia specialists were present, including Mr. W. Cuthbertson, Mr. Holton, Mr. S. Mortimer, Mr. Stredwick, Mr. Jones, Mr. G. Gordon, Mr. Hawes, Mr. J. B. Riding, Mr. H. G. Oliver, Mr. Davison, etc.

The president opened the proceedings by a few remarks upon "Pompon Dahlias," and then invited Mr. S. Mortimer to say what a good pompon should be like. The latter referred to Mrs. Gladstone, a fine show variety, and said that pompons should, on a small scale, be as good in form as it. The bloom should be round, firm, on long stems, and with regular cupped florets, and a properly developed centre. Mr. Holton gave Emily Hopper as an ideal pompon dahlia for exhibition purposes, and he deprecated the fact that many judges gave prizes to the smallest blooms, often when these were only partially developed. He thought the flowers should be fully developed to receive an award. Mr. J. B. Riding said what was wanting was a clear definition of what a pompon dahlia for show purposes should be. He also agreed that half-developed blooms were frequently given a first prize simply because they were small in comparison with the fully-developed ones. In suburban shows, on the other hand, the largest blooms were usually given the prizes. In late years the plants had grown too rampantly, and to steady down the plants growing in this fashion some of the blooms should be allowed to remain and partly seed, so that the extreme vigour would be retarded, and the succeeding flowers would then come about the right size and of good form. When the plant had been steadied in this respect the old flowers should be picked off.

Mr. Mawley asked for further remarks, but as these were not forthcoming he thanked those who had spoken for the information they had given.

He then called upon Mr. Holton, dahlia specialist to Messrs. J. Cheal and Sons, to read a paper on "Single Dahlias," prepared by Mr. Joseph Cheal, who was unavoidably absent owing to indisposition.

SINGLE DAHLIAS.

For display of colour in the garden the single dahlia is unequalled, and this is the original and natural form of flower. By many years of skilful culture and selection, many other wonderful and beautiful forms have been evolved, but the same skill and care brought to bear upon the singles has produced blooms of marvellous forms and beauty of colouring.

The propagation and preparation of plants is precisely the same as with other dahlias. It is quite easy to raise any number from seed, and well-selected seed should produce a large percentage of really good flowers, but where space is limited and definite colours and heights are required, it is not well to rely upon seedlings, but to use those that have been propagated from known varieties so that beds and borders can be planted with definite colours and sizes that have been produced after years of careful hybridisation and selection. If seedlings are planted, some amongst them may prove to be of the best quality, but they will vary much in colour, size, and habit, so that much time will be saved and better results obtained by planting only selected varieties.

For display in the garden they may be planted in borders, either in lines or groups of colour, with tall varieties at the back and grading down to quite dwarf plants in front. They are also most effective if planted in clumps on grass, and they greatly help to enliven shrubbery borders if a few are planted between the shrubs. Between shrubs, however, the soil is usually impoverished, and it is needful to prepare the holes with fresh soil and manure. In the case of new plantations where for several years the shrubs do not cover all the ground it is an excellent plan to fill open spaces with dahlias.

THE BEST VARIETIES.

With the object of ascertaining which were really the most effective and up-to-date varieties for display in the garden, a trial was conducted at the Lowfield Nurseries in 1910, for the National Dahlia Society. A large number were grown in open quarters, where the best varieties from the leading raisers were grown side by side. The committee, after carefully examining the whole of the varieties, selected the following for recommendation as the best for profuse flowering, habit of plant, and quality of flowers combined:

Cardinal
Snowdrop
Peggy
Leslie Seale
Columbine
Lady Bountiful
Rosy Gem
Mrs. Joynson Hicks
Butterfly
Miss Roberts
Kitty
Owen Thomas
Amy
Mrs. W. Wood
Vesuvius
Rosebank Scarlet
Miss Morland
Fugi San
Winona
Ensign
Morning Glow

PREPARATION OF SOIL.

Any ordinary soil will do for the single dahlia, but it should be dug or trenched in autumn with a moderate quantity only of manure, and the surface left rough for winter frosts. The plants may be put out at the usual time with a small quantity of manure on the surface as a mulching.

The plants should be immediately staked, but do not use stakes that are too tall. One often sees tall stakes standing far above the plants after they have attained their full height. It is better to use three or four small stakes, which are covered by the plant, and it is easier to tie out the branches in a more natural way to branching stakes than to one tall one in the centre.

With singles there is no need to disbud, but it is most important to go over the plants every few days and cut off all old flowers. If allowed to go to seed flowering will immediately cease, but if trimmed as above, they will continue to flower profusely until killed by autumn frost.

Black fly will frequently attack the plants during the first few weeks after planting out. To prevent this the plants should be syringed with quassia extract, and this may require to be repeated two or three times to keep the plants clean and healthy.

SINGLES FOR CUTTING.

Many growers have doubtless been disappointed and even disgusted with the singles for cutting purposes because they drop their flowers so soon after cutting.

This fault is entirely avoidable if the flowers are cut young. Always select flowers that have not fully expanded, and before the bees have touched them. Where it is desired to have a stem longer than the flower stalk, immediately cut off all leaves, as those that are left on the stem cause the flowers to drop much sooner than if they are cleared.

The best time to cut is early in the morning, and they should at once be placed in water, and, if possible, allowed to remain for some time in a cool shady place. Flowers cut and prepared in this way will keep fresh for several days.

The flowers may then be arranged in vases, epergnes, or baskets as desired. As to foliage it is always safe to follow nature and arrange with their own foliage and buds, but for this purpose it should always be cut separately. Effective combinations, however, can also be obtained by using other suitable foliage, grasses, and berries.

For exhibition cut and prepare exactly as above described. In arranging bunches it is needful to wire the flowers in order to form a good symmetrical bunch, and for this it is a great saving of time to use the prepared wire frames upon which the flowers can be quickly arranged and fresh foliage and buds placed behind the flowers.

If these simple directions are followed as to cultivation and cutting, the single dahlia will give the greatest satisfaction, both in the garden, the house, and on the exhibition table.

Mr. Holton gave some reminiscences after reading the paper, and said that great improvements had been made in recent years, and now the varieties were excellent for garden decoration and other purposes. He said that every few days the old flowers should be removed, and seed pods not allowed to form, and then very little further attention was needed. He believed there was a great future for single dahlias.

Mr. Mawley referred to the great work of the late Mr. Girdlestone,and said he always used foliage from starved plants of Glare of the Garden for association with his exhibition flowers. He thought his own border of single dahlias was the gayest in the kingdom during the autumn. Single dahlias needed very little attention beyond the removal of old flowers, after planting and staking, and, therefore, deserved extended cultivation. Mr. Holton said he always used foliage from pot-rooted plants.

Mr. W. Cuthbertson said single flowers had always appealed more to him than any others. At Edinburgh last year they had planted hundreds of plants of many kinds of dahlias, but the finest display was made by the single dahlias. He thought the formal setting up of single dahlias, as generally followed, did nothing at all to help forward the popularity of dahlias. He thought many dahlia experts should reconsider their present methods of exhibiting dahlias, so as to present the flowers in a more natural way to the public. He saw a grand hedge of single dahlias at the Earl of Haddington's garden at Tynninghame, all produced from two-year-old plants, set out six feet apart, these making a glorious and continuous display for two months. Mr. Jones, formerly at Rothesay, said he had gone back to the old formal methods of exhibiting because by that means he produced a rare blaze of colour, setting them up in triangular wire frames, ten blooms in a bunch; further, this method permitted easy packing and the dispatch of flowers from long distances, whereas flowers staged loosely were, in his opinion, less effective, and far more difficult to pack and carry. Mr. Holton advised cutting the flowers when three parts developed, and placing them in water in a cool shed before packing them for the show.

Mr. J. B. Riding objected to the use of "gridirons" for the display of single and some other dahlias, and urged the display of the flowers in a more natural manner. Indeed, he urged that the single dahlia was not intended to be an exhibition flower. The single dahlias had lost their popularity because people did not understand them, and they thought that all that was necessary was to sow a packet of seeds, and from the plants pick good single flowers all the season. Too many exhibitors picked their flowers at a too far advanced stage, and he confirmed the remarks of other speakers in this respect, and also in the regular and frequent removal of old flowers.

Mr. J. B. Riding then, by request, made a few remarks anent colarette dahlias, and said that these varieties, of which he had grown the largest possible number obtainable, were more long-lived than singles proper, and quite as free flowering. The set, as at present known, included a good many that are of no use, and, he was sorry to say, the Continental nomenclature of varieties was in hopeless confusion. Mr. Mawley briefly gathered up the main points, and urged that amateurs should leave the raising of single dahlias from seed severely alone.

DECORATIVE DAHLIAS FOR THE GARDEN.

Mr. G. Gordon, V.M.H., then proceeded to deal with dahlias of special value for decorative effect in the garden.

Mr. Gordon said he did not intend speaking of decorative dahlias as usually understood, but of dahlias that, under ordinary good culture would be of value for decorative effect in the garden. They may be tall or dwarf or of medium height; they may be show, fancy, cactus, singles, pompons, pæony-flowered, colarette, or the varieties known as decorative. He was not specially concerned with the section to which they belonged, but he was anxious to avoid exalting one group at the expense of another, for he felt that all the classes should obtain full recognition, and that at least several should be represented in gardens in which dahlias were systematically cultivated. It was essential in the interest of the dahlia and the garden that raisers and growers should carefully consider whether the time had not arrived when a new departure should be made with a view to the creation of varieties specially adapted for beautifying the garden. He did not suggest that dahlias which by reason of the perfection of form of their flowers are specially adapted for exhibition should be in any way neglected, but he regarded it as a serious mistake that raisers should for many years past have concentrated their energies on the production of exhibition varieties and the National Dahlia Society should have failed until within a very recent period to adequately encourage varieties other than those of value for competitive purposes.

What is wanted at the present time is dahlias of good habit; in other words varieties that have a sturdy, free-branching growth, and great freedom of flowering. It was also essential that the flowers be borne on stems of sufficient length to carry them well above the foliage, because freedom of blooming is of little value so far as colour effects in the garden are concerned if the blooms are hidden away among the leaves.

It would appear that dahlia raisers and dahlia fanciers have taken an altogether too narrow view of the dahlia as a generally useful garden flower. For long, long years every effort has, practically speaking, been devoted to the production of exhibition varieties and exhibition blooms, and, unfortunately, societies that have in any way recognised dahlias by providing classes for them in their schedules have given encouragement thereto. This is practically the reason why the National Dahlia Socety became somewhat moribund, and for some time failed to enjoy the prosperity which a society associated with so important a class of flowers should possess. Happily, there had been a change of policy, and this justified the hope that dahlias for all purposes would receive recognition and encouragement. It is quite certain that if the society is to fulfil its mission strenuous endeavour must be made to make the dahlia a popular garden flower, and it is therefore gratifying to know that the executive are beginning to appreciate this important fact.

The history of the National Rose Society, the National Carnation Society, and the National Chrysanthemum Society afforded ample evidence of the importance of a floricultural society taking a broad view of its work, and not losing sight of the fact that the proper place for the flowers with which it is associated is the garden. While the National Rose Society devoted nearly the whole of its attention to exhibition roses it was a small body with a few hundred members; but now, as the result of a change in its policy, and a full recognition of roses for the garden, it had between 4,000 and 5,000 members. Again, the National Carnation Society was for a long time stationary until the late Mr. Martin Smith, at a conference at Chiswick boldly condemned the practice of giving almost exclusive attention to the cultivation of carnations for exhibition, and by methods that necessitated the use of glass. The condemnation had the desired effect. Border varieties and border culture were liberally encouraged, and an immense impetus given to cultivation. The National Chrysanthemum Society in like manner gave itself up wholly to the cultivation of exhibition varieties, and suffered accordingly. But it is once again showing renewed life, and trade growers are benefited, as the result of the attention it has devoted, and is devoting, to improved varieties for the decoration of the garden and conservatory, and the supply of cut blooms for the embellishment of the home.

These historical facts are of special interest as evidence that no floricultural society can flourish when it gets into a groove so narrow as to prevent it seeing more than one side of work that has many aspects. They are evidence also that the flowers suffer from a want of breadth in the policy of the societies associated with them, and that a change of policy by which both decorative and exhibition varieties receive equal encouragement invariably proves beneficial both to the society and the cult it represents.

Besides, said Mr. Gordon, producing varieties of fine habit and with long-stemmed flowers and remarkable for their effective colouring, it was essential strenuous efforts should be made to increase the length of the dahlia season by the production of varieties that come into bloom earlier. It would seem to him that there was room for a new race that would be to the dahlia what the early-flowering chrysanthemums are to the November and exhibition varieties. In other words we must have a longer dahlia season if the flower is to become, in any measure, as popular as the rose, the chrysanthemum, the carnation, and the sweet pea. We must have dahlias that, under ordinary cultivation, will be in full bloom by the beginning of August, and continue to yield up their floral wealth until the frost comes in the autumn. It was not sufficient that dahlias should be at their best in September, for if their season extended over a few weeks only they did not justify the time and space devoted to them. Happily there was a foundation available for such race, and as raisers had of late devoted some of their attention to the creation of garden varieties, and already achieved considerable success, there was full justification for the anticipation that at no distant date an immense improvement will be manifest.

Mr. Cuthbertson thoroughly agreed that the introduction of the show cactus dahlia and the great efforts put forward in its cultivation had kept back the extended growth of dahlias as garden flowers. Probably 90 per cent. of dahlia growers never competed. In America the flower was grown almost solely for garden effect, and little for purely exhibition purposes. The dahlia has three strong competitors—the H.T. rose, the waved sweet pea, and the early chrysanthemum, therefore there was a need for great work in securing earlier and longer-flowering varieties, so that the dahlia might occupy a rightful position in the floricultural world.

Mr. Hawes expressed himself as entirely in favour of dahlias for garden decoration, and said that he considered that the future of the National Dahlia Society depended almost entirely upon the stand it would take in this respect. Some pæony-flowered varieties were good for garden decoration, but there was room for great improvement. Mr. Curtis and Mr. J. B. Riding emphasised the chief points, and gave it as their opinion that there was great need for the evolution of varieties of dahlias that will come fully into flower early in August. Mr. Riding thought the N.D.S. had itself more or less killed the popularity of the dahlia by certificating varieties of value only for exhibition purposes. He thought, however, there was a turn for the better, and he hoped that in time the dahlia for garden decoration would be forthcoming from the raisers. We needed to go back to varieties like Amos Perry, and from these raise new and improved and early varieties.

Mr. W. Cuthbertson brought the proceedings to a close by moving a vote of thanks to those who had contributed papers, and Mr. Mawley for presiding; this was seconded by Mr. S. Mortimer, and carried with acclamation.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, MARCH 14.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair), Sir Everard im Thurn, Sir John T. D. Llewelyn, Dr. O. Stapf, Dr. J. A.

Voelcker, Messrs. C. T. Druery, J. Douglas, A. Worsley, E. M. Holmes, J. T. Bennett-Poë, W. Cuthbertson, J. Fraser, G. Gordon, and F. J. Chittenden (hon. secretary).

PRIMULA STELLATA, ABNORMALITIES IN.—Mr. A. Worsley showed flowers of P. stellata having two to five antipetalous outgrowths at the throat, the flowers being otherwise normal. The outgrowths were similar in structure to the petals, but only about half the size and reversed, i.e., having the dark red surface opposed to the dark red surface of the petals and the paler surface turned towards the centre of the flower (and similar in colour to the outer surface of the corolla).

GREEN PRIMROSE.—Mr. J. Fitt, of The Frythe Gardens, Welwyn, showed a well-grown plant of the long-known primrose with virescent petals. In the present instance the petals showed rather more of the leaf-like character than usual, the venation being very distinct. The plant had been found growing wild near Welwyn two years ago.

RHODODENDRON GRANDE.—Sir John Llewelyn showed flowers from a seedling Rhododendron grande gathered in the open. The plant, with others, had been raised from seed received from the late Sir George King, from Calcutta, but had never before flowered, the flower-buds having always previously been destroyed by frost. All the other plants raised at the same time came into flower six weeks later. The instance is an interesting one of a persistent and apparently congenital one of variation from the normal time of flowering and quite independent of climatic conditions. Similar instances occur in other species of rhododendron, particularly R. arboreum.

DISEASE OF CELERY.—Mr. Chittenden commented upon the widespread character of, and great loss occasioned by the disease of celery due to the fungus Septoria petroselini var. Apii during the past year. He drew attention to the fact that a considerable amount of celery "seed" on the market, including samples grown in England and on the Continent, showed the perithecia containing ripe spores of the fungus. Klebahn has recently shown that the spores from affected "seed" are capable of reproducing the disease, and as so much of the seed seems likely to contain spores, the desirability of special attention to celery during the coming season is indicated. If the foliage shows the least sign of the disease by the development of small brown spots, the plants should be sprayed with potassium sulphide or with Bordeaux mixture at once, the spraying being repeated if necessary.

CERTIFICATES TO PLANTS OF SCIENTIFIC INTEREST.—Mr. Worsley brought forward a resolution upon the question of granting certificates to plants shown before the committee. The fact that the Botanical Certificate had (erroneously) come to be looked upon as an award to be made to a plant of no decorative or commercial value was commented upon. The actual intention of the Botanical Certificate was to encourage the introduction and cultivation of plants of intrinsic interest or of potential value, and it is, as stated in the "Book of Arrangements," intended to be awarded to "Plants newly discovered or raised, and of botanical interest irrespective of decorative value." After further discussion, a sub-committee was re-appointed to select plants at each meeting for the full committee's consideration, the sub-committee consisting of Messrs. J. T. Bennett-Poë, J. Douglas, C. T. Druery, and A. Worsley. The further discussion of the question was adjourned until the next meeting.

British Gardeners' Association.

The usual monthly meeting of the London branch took place at Carr's Restaurant, on Thursday, March 9. Mr. North presided, and there was an average attendance of forty members present. On the motion of Mr. Hawes, it was resolved to send two guineas as a donation to the Royal Gardeners' Orphan Fund from the proceeds of the concert held on February 25. A very interesting address on "A Young Gardener's Education" was given by Mr. Thomas Bevan, chairman of the Executive Council of the B.G.A. The speaker traced the gardener's career from garden boy to head gardener, and from his long and varied experience in gardening he was able to give much valuable and practical advice to those young gardeners who are desirous of becoming shining lights in their profession.

The following points were strongly emphasised by Mr. Bevan: The power of observation should be carefully cultivated, and a diary kept to note the time of seed sowings, rotation of crops, budding arrangements, and other gardening operations. The study of horticultural knowledge, both practical and theoretical, should be systematically carried out; always endeavour to learn the why and wherefore of all you see done, and never be afraid or too proud to ask questions. Read the horticultural papers regularly, visit gardens of interest in the neighbourhood, and attend flower shows whenever possible. Young gardeners should not confine themselves to one area, but endeavour to gain a varied experience by going to various parts of the country. Above all, learn to work and think.

An interesting and animated discussion followed, which was taken part in by many of those present.

A hearty vote of thanks to Mr. Bevan brought the meeting to a close.

Royal International Horticultural Exhibition, 1912.

For the purpose of assisting in the promotion of this exhibition, the Executive Committee invited prominent horticulturists in the various counties to act as provincial secretaries. The first duty of these secretaries was to get together a committee and chairman for each county. These committees will do what is possible to encourage local cultivators to participate in the exhibition. They will also endeavour to obtain subscriptions and guarantees, and in various ways popularise the exhibition in the counties. At the invitation of the Executive Committee a number of the secretaries, including representatives from Wales and Ireland, attended a meeting on the 14th inst., at the Hotel Windsor, Westminster, for the purpose of conferring as to the best means of carrying out their work, and for the purpose of hearing from the chairman of the Executive Committee, Mr. J. Gurney Fowler, some information upon the progress which has been made since the last meeting. Mr. Fowler first delivered an address, in which he showed that everything was being done to push forward the work of organisation as rapidly as possible, and he described the ways in which the provincial committees could best support the efforts of the Executive Committee. Following the chairman's address, there were speeches from many of the provincial representatives, some of whom sought information. On the whole the reports were of a reassuring character, for whilst some had encountered considerable difficulties in their initial proceedings, others had succeeded in gaining the support of all whom they had approached. On behalf of the Executive Committee, Mr. Fowler promised that certain suggestions advanced by the delegates should be adopted. In the evening of the same day the party joined the members of the Horticultural Club at dinner.

Bristol Gardeners' Association.

This society received its annual visit from the Bristol Amateur Society on March 9 at St. John's Parish Rooms, when Mr. Hayball presided over a large attendance.

A paper on "Rose Culture" was given by Mr. Harris, of the visiting society, and in a brief history of the rose, Mr. Harris went as far back as 600 years B.C. He spoke from an amateur's standpoint throughout his paper. He said a situation should be chosen little liable to severe frost or strong wind; pure air was essential; the soil most suitable is a strong, deep, heavy loam, resting on gravel or chalk. His advice was to trench deeply, and incorporate grit, road-scrapings, burnt clay, and manure; plant early, and cover the point of union. The lecturer strongly recommended the use of liquid manure in May or June when roses are growing freely.

For two pots of narcissus, Mr. Shelton was first, Mr. Ayres second, and Mr. T. Clark third. In the point competition Mr. Woodward received six for Cattleya Trianæ, and three for violets; Mr. Hunking four for Cattleya Schroderæ, and Mr. Scott two for a seedling hellebore.

FORTHCOMING ENGAGEMENTS.

TUESDAY, March 28.—Royal Horticultural Society; Daffodil Committee meets at 11.30 a.m.; Fruit, Floral, and Orchid Committees, at 12 o'clock; lecture at 3 p.m. on "Alpines in their Native Homes," by Mr. R. C. Reginald Nevill; Scientific Committee, at 4 o'clock.

WEDNESDAY, March 29.—Irish Gardeners' Association and Benevolent Society meets.

THURSDAY, March 30.—Torquay Spring Flower

SATURDAY, April 1.—Paisley Florists' Spring Show.

TUESDAY, April 4.—Truro Spring Show; two days.

Bournemouth Spring Show; two days.

Scottish Horticultural Association meeting.

WEDNESDAY, April 5.—Liverpool Spring Show; two days.

Royal Horticultural Society's general examination in Horticulture.

THURSDAY, April 6.—Linnean Society meets.

FRIDAY, April 7.—Kingsbridge Daffodil Society.

MONDAY, April 10.—United Horticultural Benefit and Provident Society, committee meeting.

TUESDAY, April 11.—Royal Horticultural Society; Daffodil Committee meets at 11.30; Fruit, Floral, and Orchid Committees at 12 o'clock; lecture at 3 p.m. on "The Origin and Structure of Aquatic Flowering Plants," by the Rev. Prof. G. Henslow, V.M.H.; Scientific Committee at 4 o'clock.

WEDNESDAY, April 19.—Royal Horticultural Society of Ireland; Spring Show.

Devon Spring Flower Show, at Plymouth; two days.

THURSDAY, April 20.—Ipswich Spring Show.

TUESDAY, April 25.—Royal Horticultural Society; Daffodil Committee meets at 11.30; Fruit, Floral, and Orchid Committees at 12 o'clock; lecture at 3 p.m. on "The Tulip—Its Problems and History," by Rev. J. Jacob; Scientific Committee at 4 o'clock.

Eckford's Giant Sweet Peas

The Finest Blooms

that blossom on the Sweet Pea Plant are grown from Eckford's famous seeds. Eckford, the Sweet Pea Specialist, supplies only seeds that are bound to give good results. Eckford's seeds flower brilliantly, give brighter colours, longer stems, larger flowers, and succeed even in the most difficult soils.

ECKFORD'S are the largest retailers of Sweet Peas in the world, and do not supply the trade.

Villa (B) Collection.
24 Splendid varieties, suitable for exhibition, 50 seeds of each, **5/6**, post free for cash.

Villa (C) Collection.
12 Splendid varieties, suitable for exhibition, 50 seeds of each, **2/9**, post free for cash.

Villa (E) Collection.
12 Extra varieties, suitable for exhibition, 25 seeds of each, **1/6**, post free for cash.

A specially written booklet on Sweet Pea Growing given with every order.

For full list of Special Novelties see next week's issue.

FREE. Send a postcard to-day for large Illustrated and Coloured Catalogue. It gives full particulars of all novelties in Sweet Peas for 1911, and contains full list of all flower and vegetable seeds.

HENRY ECKFORD, F.R.H.S.
(Dept. 221), Wem, Shropshire.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

PLANTING WATER LILIES.—J. B., Malvern: You will find an article in the present issue giving just the information you require.

HARDY PRIMULA SEEDS.—G. F., Weymouth: As a general rule the best time to sow seeds of the hardy primulas is directly they are ripe. Cold frames will provide ample shelter for the seed beds or boxes, and such shelter as is needed chiefly for the purpose of throwing off heavy rains.

SPOTTED STRAWBERRY LEAVES.—A. C. R., Iping: The leaves sent show a very bad attack of the fungus known as Strawberry Leaf Spot (Sphærella fragariæ). Bordeaux mixture at half the normal strength should be sprayed over and among the plants directly an attack is noticed, and, where the disease has been prevalent the strawberry plants should be sprayed in early spring, when the new leaves appear. More than one spraying may be desirable in the early spring, but spraying must cease just before the flowers open. An excellent method of getting rid of the pest is to adopt somewhat drastic methods in the early autumn. Sprinkle thin layers of straw over the entire bed, and set it on fire; by this means the old infected leaves and all debris holding fungus spores will be burned up. If this is followed by hoeing and light manurial dressings a luxuriant growth of healthy and vigorous foliage will follow. In the succeeding spring a spraying with weak Bordeaux mixture should be given as a preventive.

CLEMATIS.—J. C., Epsom: Clematises may be propagated by the common method of layering, but the branch layered must not be separated from the parent before it is thoroughly well rooted. Pieces of growth cut up into portions, each with at least one eye, will root in brisk heat, in sandy soil, if inserted in spring. Most of the garden varieties are increased by the growers by means of root grafting in spring, in a warm house. The kinds most used as stocks are Clematis vitalba, C. viticella, and C. flammula. Clematises like a rather rich soil, containing a fair proportion of lime, so that lime rubble may, in most cases, be advantageously added to the garden soil. A mulching of rotten manure in the autumn, and a similar dressing in early summer, will materially aid growth and flower production.

PLANTING CHRISTMAS ROSES.—L. E. S., March: Some few years ago we dealt at some length with the preparation of permanent beds for Christmas roses for the purpose of providing an abundance of fine clean flowers during the winter. The work should be carried out without delay. The site for the bed must be marked out according to the size of the frames to be used, and the prospective demand. If the natural soil is at all doubtful, heavy, or over a wet subsoil, it should be removed to the depth of 2ft.; after breaking up the subsoil put in six inches of brick rubble and clinkers, covering this with a good layer of last season's leaves or inverted turves. Then fill up the space with a mixture of turfy loam, peat, leaf-soil, road grit, and a little half-decayed manure. Make all this quite firm, and then plant out the hellebores after carefully pulling the old plants into pieces about six inches in diameter. Press the soil firmly about the roots, only just bury the crowns, and leave six clear inches of space between the plants. Put the frames in position, and keep the lights on for a little while to encourage growth. In May apply a light top-dressing of leaf-mould and old hotbed manure. Ventilate freely after the plants are established, presently removing the lights entirely. Give water as occasion demands, and when the growth for the year has finished remove the frames from the bed, returning them during October, but only putting the lights on in bad weather until the flowers begin to open, when they should remain in position, tilted, to keep the blooms clean.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

W. B. C., Ruabon.—1, Odontoglossum cirrhosum; 2, Fuchsia procumbens.

J. D. L., Warwick.—1, Abies Douglasi; 2, Pinus pinea; 3, Ruscus aculeatus; 4, Viola gracilis.

H. H. S., Dunstable.—1, Saxifraga sancta; 2, Anemone blanda; 3, Adonis amurensis; 4, Saxifraga apiculata.

A. H., Chester.—1, Dendrobium signatum; 2, Eucharis candida; 3, Areca lutescens; 4, Coleus thyrsoideus; 5, Hibbertia dentata.

E. S., Esher.—1, Primula rosea; 2, P. frondosa; 3, Ribes sanguinea; 4, Cornus Mas; 5, Ulmus campestris; 6, Chionodoxa Luciliæ.

L. S. M., Winchcombe.—1, Rhododendron præcox; 2, Primula denticulata Cashmeriana; 3, Kalmia latifolia; 4, Sempervivum arachnoideum.

CATALOGUES RECEIVED.

SUTTON AND SONS, READING.—The Farmers' Year Book and Graziers' Manual, is, as usual, an excellent catalogue of good things in the way of roots and fodder crops of all kinds.

AMOS PERRY, ENFIELD.—Florists' flowers, chiefly hardy kinds, form the contents of Mr. Perry's spring issue; pentstemons figure largely, and a coloured plate of these beautiful flowers is included; phloxes, delphiniums, carnations, pinks, and pyrethrums, are also treated at length.

BEES, LTD., MILL STREET, LIVERPOOL.—A catalogue of 134 pages is devoted mainly to descriptions of hardy herbaceous plants, alpines, and the new hardy primulas (illustrated), but pot roses, dahlias, chrysanthemums, and bedding plants receive a full share of attention.

THOS. S. WARE, LTD., FELTHAM, MIDDLESEX.—Under the title of "Hardy Plants for Herbaceous Borders and Rockeries, Water and Bog Gardens," the Feltham firm has issued a most interesting and descriptive catalogue, the value of which is greatly enhanced by the inclusion of excellent views of rock and water gardens, herbaceous borders, and specimen plants.

"CARRUSTICIDE."

The Best and Cheapest Remedy for Carnation Rust and other Fungoid Diseases.

A well-known Carnation Grower writes:

Dear Sir, The Nurseries, March, Cambs.

"During the 27 years I have been growing Carnations (Perpetual and American) I have tried most of the fungicides placed on the market, but yours is the best. It is a pleasure to see how "Carrusticide" catches hold of the Rust and destroys it. I should say your preparation will be extensively used when it is better known." Yours very truly,

GEO. CLARKE.

One gallon makes 25 gallons for spraying purposes—Price 3s. per quart, 7s. 6d. per gallon. Special quotations for larger quantities.

LATEST SUCCESS.

GRAND PRIX AND GOLD MEDAL.
Japan-British Exhibition, White City. (The only Grand Prix awarded for border plants anywhere during 1910.) Unanimous award of the International Jury to Kelway and Son for Pæonies, Delphiniums, Gladioli, Pyrethrums, etc.
Kelway's Manual of Horticulture, 2s., post free, on demand.
LANGPORT, SOMERSET.

THE KELWAY ARTISTIC BORDER ensures a garden of enduring beauty from early spring to late Autumn with a minimum of cultivation, and without the trouble of constant digging or bedding-out. The plants composing the border are selected by experts, and include some of Kelway's improvements in Pæonies, Delphiniums, etc. Send dimensions of spaces to be filled, or for Kelway's "Gardens of Delight," 6d. The cost of this border is 15s. or 25s. for every 10 square yards.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

KELWAY'S MANUAL OF HORTICULTURE is the best of all Garden Books. 2s. post free.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

NOW IS THE TIME TO PLANT KELWAY DELPHINIUMS, which have been improved almost out of recognition in the past twenty years. They produce plants ranging in height from four to eight feet, exceptionally hardy and with a rich profusion of choice blooms in all the shades of blue.
Choice named varieties: 24s., 34s., and 56s. a dozen.
The celebrated present-day Delphiniums, and nearly all the best well-known varieties shown at exhibitions, originated in Kelway's Langport Nurseries.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

FIDLER'S NEW ILLUSTRATED CATALOGUE OF CHOICE GARDEN SEEDS will be sent, post free, to any address on receipt of postcard. Write at once for a copy. It may help you to save 50% on your seed bill this season. FIDLER and SONS, Royal Berks Seed Stores, Reading.

THE POPULARITY OF XL ALL SPECIALITIES increases every year. All gardeners proclaim that nothing equals these celebrated preparations.

XL ALL NICOTINE VAPORISING COMPOUND, the gardener's favourite Fumigant, both Liquid and Cake.

XL ALL NICOTINE INSECTICIDE WASH for Syringing, Dipping, and Dressing Fruit Trees and Plants. Mealy Bug, Scale, etc., cannot exist where this is used.

XL ALL INSECTICIDE WASH B (sine Nicotine), best non-poisonous Wash on the Market. No licence required to sell this. Other preparations of great renown both poisonous and non-poisonous are XL ALL WEED KILLER, XL ALL FERTILISER, RICHARDS' ARSENATE OF LEAD PASTE, CUCASA POWDER (fungicide), etc. Don't forget to ask your N.S. or Florist for Richards' small pink list.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

The North of England Horticultural Society.

Having watched with much interest the steps that have been taken within the past few months in founding a society whose object shall be the advancement of horticulture in the Northern counties of England, it was with much pleasure that we were able to record in our last week's issue the fact that the first meeting of the North of England Horticultural Society was attended with a large measure of success. The council of the society have not as yet, perhaps, found the best possible building in Leeds in which to hold the meetings. Emmanuel Hall is rather a long way from the railway station, and, while well adapted to the purpose to which it was put on the occasion of the first meeting, it ought not for any length of time to be big enough to properly accommodate the contributions from the private gardens and nurseries in the North. There was a fair representation of the various classes of plants that now find favour for the season, but the products were chiefly from nurserymen, the Leeds amateurs, as exhibitors, being conspicuous by their absence. This is much to be regretted, for unless the amateurs contribute with some degree of liberality of the choicest products of their gardens and plant houses, and thereby induce their friends to attend the meetings, the nurserymen, and especially those from long distances, will stop away. Nor can it be said that the northern nurserymen supported the council in a manner that might have been expected, having regard to what has been said about the establishment of such a society. Several southern firms came forward in fine style, and showed an excellent spirit in bringing their plants and flowers, but the display could not be regarded in any sense as representative of the spirit and skill of the northern cultivators. To this fact we have felt it desirable to direct special attention because, after all, upon the latter the success or failure of the venture must depend. Further, it cannot be too clearly stated that the public must be educated up to an appreciation of these monthly exhibitions, and thus ensure a good attendance of visitors, because, unless visitors are numerous, exhibitors will not be forthcoming; just as, on the other hand, if the northern growers do not bring the products of their skill it will be useless to endeavour to persuade the public to attend. Trade growers exhibit, and necessarily so, chiefly for the sake of business, and it should be obvious that it would be unreasonable to expect them to incur a heavy outlay in exhibiting if there is but little, if any, return therefrom. It is for this reason that we are anxious to emphasise the great need there is for northern amateurs to support the society, especially at this period of its existence, by their exhibits and their presence, because it is upon the amateurs that the trade growers depend. The lecture given in connection with the exhibition was an unqualified success. The subject of soil sterilisation is one of immense importance to horticulturists, and it was handled in a remarkably interesting and skilful manner by Dr. Russell, who, in the course of his investigations at Rothamsted, has been successful in throwing new light on sterilisation in relation to the fertility of the soil. In the course of his lecture he pointed out the many advantages to be derived from soil sterilisation, and also some of the disadvantages, and he urged the importance of cultivators studying the subject from the practical side, and carefully recording the facts relating thereto that may come under their notice for the purpose of future reference. The animated and extended discussion that followed the lecture was a great compliment to Dr. Russell, and one that he greatly appreciated, as it brought out many points of great practical importance. On this occasion the lecture was given at 6.30 p.m., but it is intended to hold the meeting at which the lectures will be given at 3 p.m., and this will be a convenience, as it will enable visitors who come in the afternoon to hear the lecture without having to wait a considerable period after inspecting the exhibition, or making a second journey thereto. The society's programme is an ambitious one, and, therefore, requires not only substantial contributions to the exhibition, but a considerable amount of money to carry it out. It now remains to be seen whether the northern horticulturists really want such a society, and such a programme, and, if wanting them, are prepared to provide the sinews of war. We hope they really do feel the need of the society, and are prepared to do whatever may be necessary to ensure its complete success. The association with the Royal Horticultural Society should be advantageous to the northern society, more especially as the invitation is extended to the members of the committees of the former society to take part in the business of the corresponding committees at Leeds. This is a good thing, at any rate for the present, because the association of the respective committees should assist in bringing the work at London and Leeds into harmony.

MR. WILLIAM ALLAN.

Mr. William Allan, whose portrait we have the pleasure of giving in this issue, is remarkable alike for his geniality, his cultural skill, and great administrative ability; and by the splendid work he has accomplished during the long period he has had charge of the important gardens of Gunton Park, has fully justified the reputation he enjoys as one of the foremost gardeners of his day. Mr. Allan had the advantage of commencing his gardening career at Rendlesham Hall Gardens, then in charge of his father, who was a gardener of considerable eminence. He had also the advantage of serving during the probationary stage of his career under such men of commanding ability as the late Mr. D. Thomson, the late Mr. D. T. Fish, and the late Mr. J. Shepherd, and evidently the opportunities he had for the acquisition of knowledge of garden management were fully utilised. It is reasonable to infer this, for during the five years he was head gardener at Henham Hall he effected many improvements, and within a short period of his taking charge of the Gunton Park gardens they were generally regarded as among the best-managed in the United Kingdom. This reputation they have maintained to the present day. Where all things have had skill of the highest class brought to bear upon them, it is not easy to single out anything for special mention. At quite an early period Mr. Allan devoted special attention to bulbous plants, and before the beautiful Lachenalia Nelsoni became generally known it might have been seen at Gunton Park in large numbers, and in a state of development that has probably not been surpassed. Mr. Allan is perhaps best known as a cultivator of fruit, and many are his successes at the exhibitions that we have had to record during the past forty years. Especially has he been successful with grapes, pears, and strawberries, and, with reference to the last-named, it may be mentioned that he raised several varieties remarkable for their high quality, notably Gunton Park, Lord Suffield, and Empress of India. One of Mr. Allan's latest achievements has been the introduction of Norfolk Beauty apple, which, by reason of its productiveness and high quality has now taken a prominent position among the culinary apples of quite exceptional excellence. Long successful with border carnations, Mr. Allan has entered with much zest into the cultivation of perpetual-flowering varieties, and, as the result, these beautiful flowers form one of the most interesting of the many fine features of the Gunton Park gardens.

Exhibition and Garden Dahlias.—In our issue for the 8th inst. we shall devote particular attention to dahlias for garden decoration and exhibition. The several articles on these attractive flowers will have special reference to the matters requiring attention at this season of the year, and the illustrations will include portraits of several of the newer varieties that are of great value in the garden. The issue will also contain several articles and illustrations having reference to the preparations for the production of distinct effects in the flower garden during the summer months.

Horticulture at the Festival of Empire.—A great feature of the forthcoming Festival of Empire at the Crystal Palace will be the great beauty of the grounds, in which are now being erected the splendid palaces of our various overseas dominions. The 250 acres of Sydenham's slopes offer a noble field for the operations of the horticulturist, and it is hoped that British nurserymen will do their utmost to demonstrate to the world the charm and infinite variety of the English garden. Millions of people from all parts of the globe will visit the Festival of Empire between May and October, and the King and Queen will grace the gathering on State occasions. Again, the festival is under the patronage of H.M. Government, and all profits will be given to the King Edward VII. Hospital Fund. British horticulturists will have ample room at their disposal, and the presentation of Imperial awards, in the form of cups and medals, should form an extra inducement to our leading nurserymen. In addition to the planted displays in the grounds, two exhibitions of cut roses have been organised, and these will be held in specially erected structures. Full particulars can be obtained from Mr. F. G. W. Henslow, M.A., Empire House, 175, Piccadilly, W.

R.H.S. Daffodil Committee.—We understand that the council of the Royal Horticultural Society have accepted the recommendations of the Daffodil Committee in respect of a two-day show of daffodils and tulips in April, a Year Book, and the preparation of a schedule. The committee will at once proceed to appoint sub-committees for special purposes, and it is hoped when these get to work and complete their arrangements, it will be found there is no need for a National Daffodil Society. At any rate, the matter now lies chiefly with the R.H.S. Daffodil Committee.

Euonymus Mildew.—The progress of a mildew that attacks euonymuses along the South Coast is attracting a good deal of attention, and efforts are being made to stay the disease. At a recent meeting of the Bournemouth Natural Science Society Sir Daniel Morris read a paper on this subject contributed by Mr. G. Massee, F.L.S., V.M.H. Specimens were exhibited, and Sir Daniel explained how the attack spread. The removal of attacked leaves in spring, and spraying with sulphide of potassium, were suggested as remedies. It is hoped that Mr. Massee's paper, with illustrations, will soon be issued in pamphlet form.

Spraying with a Lime-sulphur Wash. To the recent issue of the "Journal" of the Board of Agriculture Mr. E. S. Salmon, F.L.S., contributes an exhaustive report on the experiments that were carried out last year in spraying apples and gooseberries in the plantations at the South-Eastern Agricultural College, Wye, and on two farms in Kent, with the lime-sulphur wash. This wash is largely used in America, and the best formula is considered to be 50lb. quicklime and 100lb. flowers of sulphur, boiled together for an hour in 50 gallons of water. Before using this concentrated solution is diluted according to requirements. In his conclusions with regard to the experiments Mr. Salmon states that no opportunity occurred for testing the value of lime-sulphur as a fungicide against apple "scab" and "black spot." As, however, it has been stated, as the result of experiments carried out in the United States, that it "is about as effective" for this purpose as Bordeaux mixture, the lime-sulphur wash may be recommended for trial in this country on those varieties of apples whose foliage or fruit will not stand spraying with Bordeaux mixture. The experiments show that while the foliage of some varieties, e.g., Worcester Pearmain, show no injury when sprayed with a lime-sulphur wash of sp. gr. 1.01, the foliage of other varieties, e.g., Cox's Orange Pippin, Charles Ross, King of the Pippins, Blenheim Orange, and Besspool (Tower of Glamis) are severely "scorched" by the wash at this strength. For such varieties a lime-sulphur wash of sp. gr. 1.005 should be used when spraying them in June or later—though possible the "full-strength" wash is safe to use in May. In fighting apple "scab" or "black spot" Bordeaux mixture still remains the best fungicide known, and should always be used for this purpose except on those varieties of apples which are liable to "Bordeaux injury." The lime-sulphur wash, as well as the iron sulphide and copper sulphide washes mentioned above, should only be used at present experimentally and on a small scale.

The King's Prize for Chrysanthemums.—His Majesty the King has presented a handsome challenge cup to be competed for at the exhibition of the Windsor, Eton, and District Chrysanthemum Society. The class specification is for eight vases of three blooms each, the cup must be won three times before becoming the absolute property of a competitor, and there must be not fewer than three competitors in any one year. The class is an open one. The forthcoming exhibition will be the twentieth the society has held, and it will take place on November 10, in the Royal Albert Institute, Windsor.

The Royal Botanic Society continues to add to its Fellowship. At the recent monthly meeting one hundred new Fellows were elected, and there were ninety-two nominations for election at the next meeting. Provided there has been no considerable leakage, the membership should now be considerable, and there ought soon to be signs of prosperity in the society's gardens, and evidence of renewed activity in other directions.

The Great African Snail (Achatina fulica), which has recently appeared in immense numbers in Ceylon, is dealt with at some length in an interesting contribution to the February issue of the "Zoologist." This species is a native of East Africa, and was introduced many years ago into Mauritius. It was introduced to Calcutta about half a century ago, and in twenty years it had become abundant in the gardens of the houses in Chominghi, while it had also crossed the Hughli to Howra and Barrakpur. Some ten years ago a collector introduced the species to his estate in the highlands of Central Ceylon, and here it increased so rapidly that very soon efforts were made to exterminate it, and it was believed that these were successful. Some, however, escaped destruction, and two were carried down with vegetables to the lowlands. The increase under warmer conditions was remarkably rapid, and the snails spread over an area of about five square miles. It was conjectured that on this area there were millions, and 227 were found on the stem of a cocoanut palm about six feet in length. The natives were alarmed for the safety of their crops, but comparatively little damage has been done. Now, without the adoption of restrictive measures, the snails are diminishing, owing, probably, to the enemies with which they have to contend in a young state.

Colonial and Indian Gardening Appointments. It is recorded in the "Kew Bulletin" that Mr. Harold Green, a member of the gardening staff of the Royal Botanic Gardens, has been appointed by the Secretary of State for the Colonies, on the recommendation of Kew, assistant superintendent of the Botanical and Forestry Department, Hong Kong.—Mr. Harry Dodd, who was appointed curator of the Botanic Station at Onitsha, Southern Nigeria, in 1906, has been appointed by the Secretary of State for India in Council, on the recommendation of Kew, a probationer gardener for service in India.

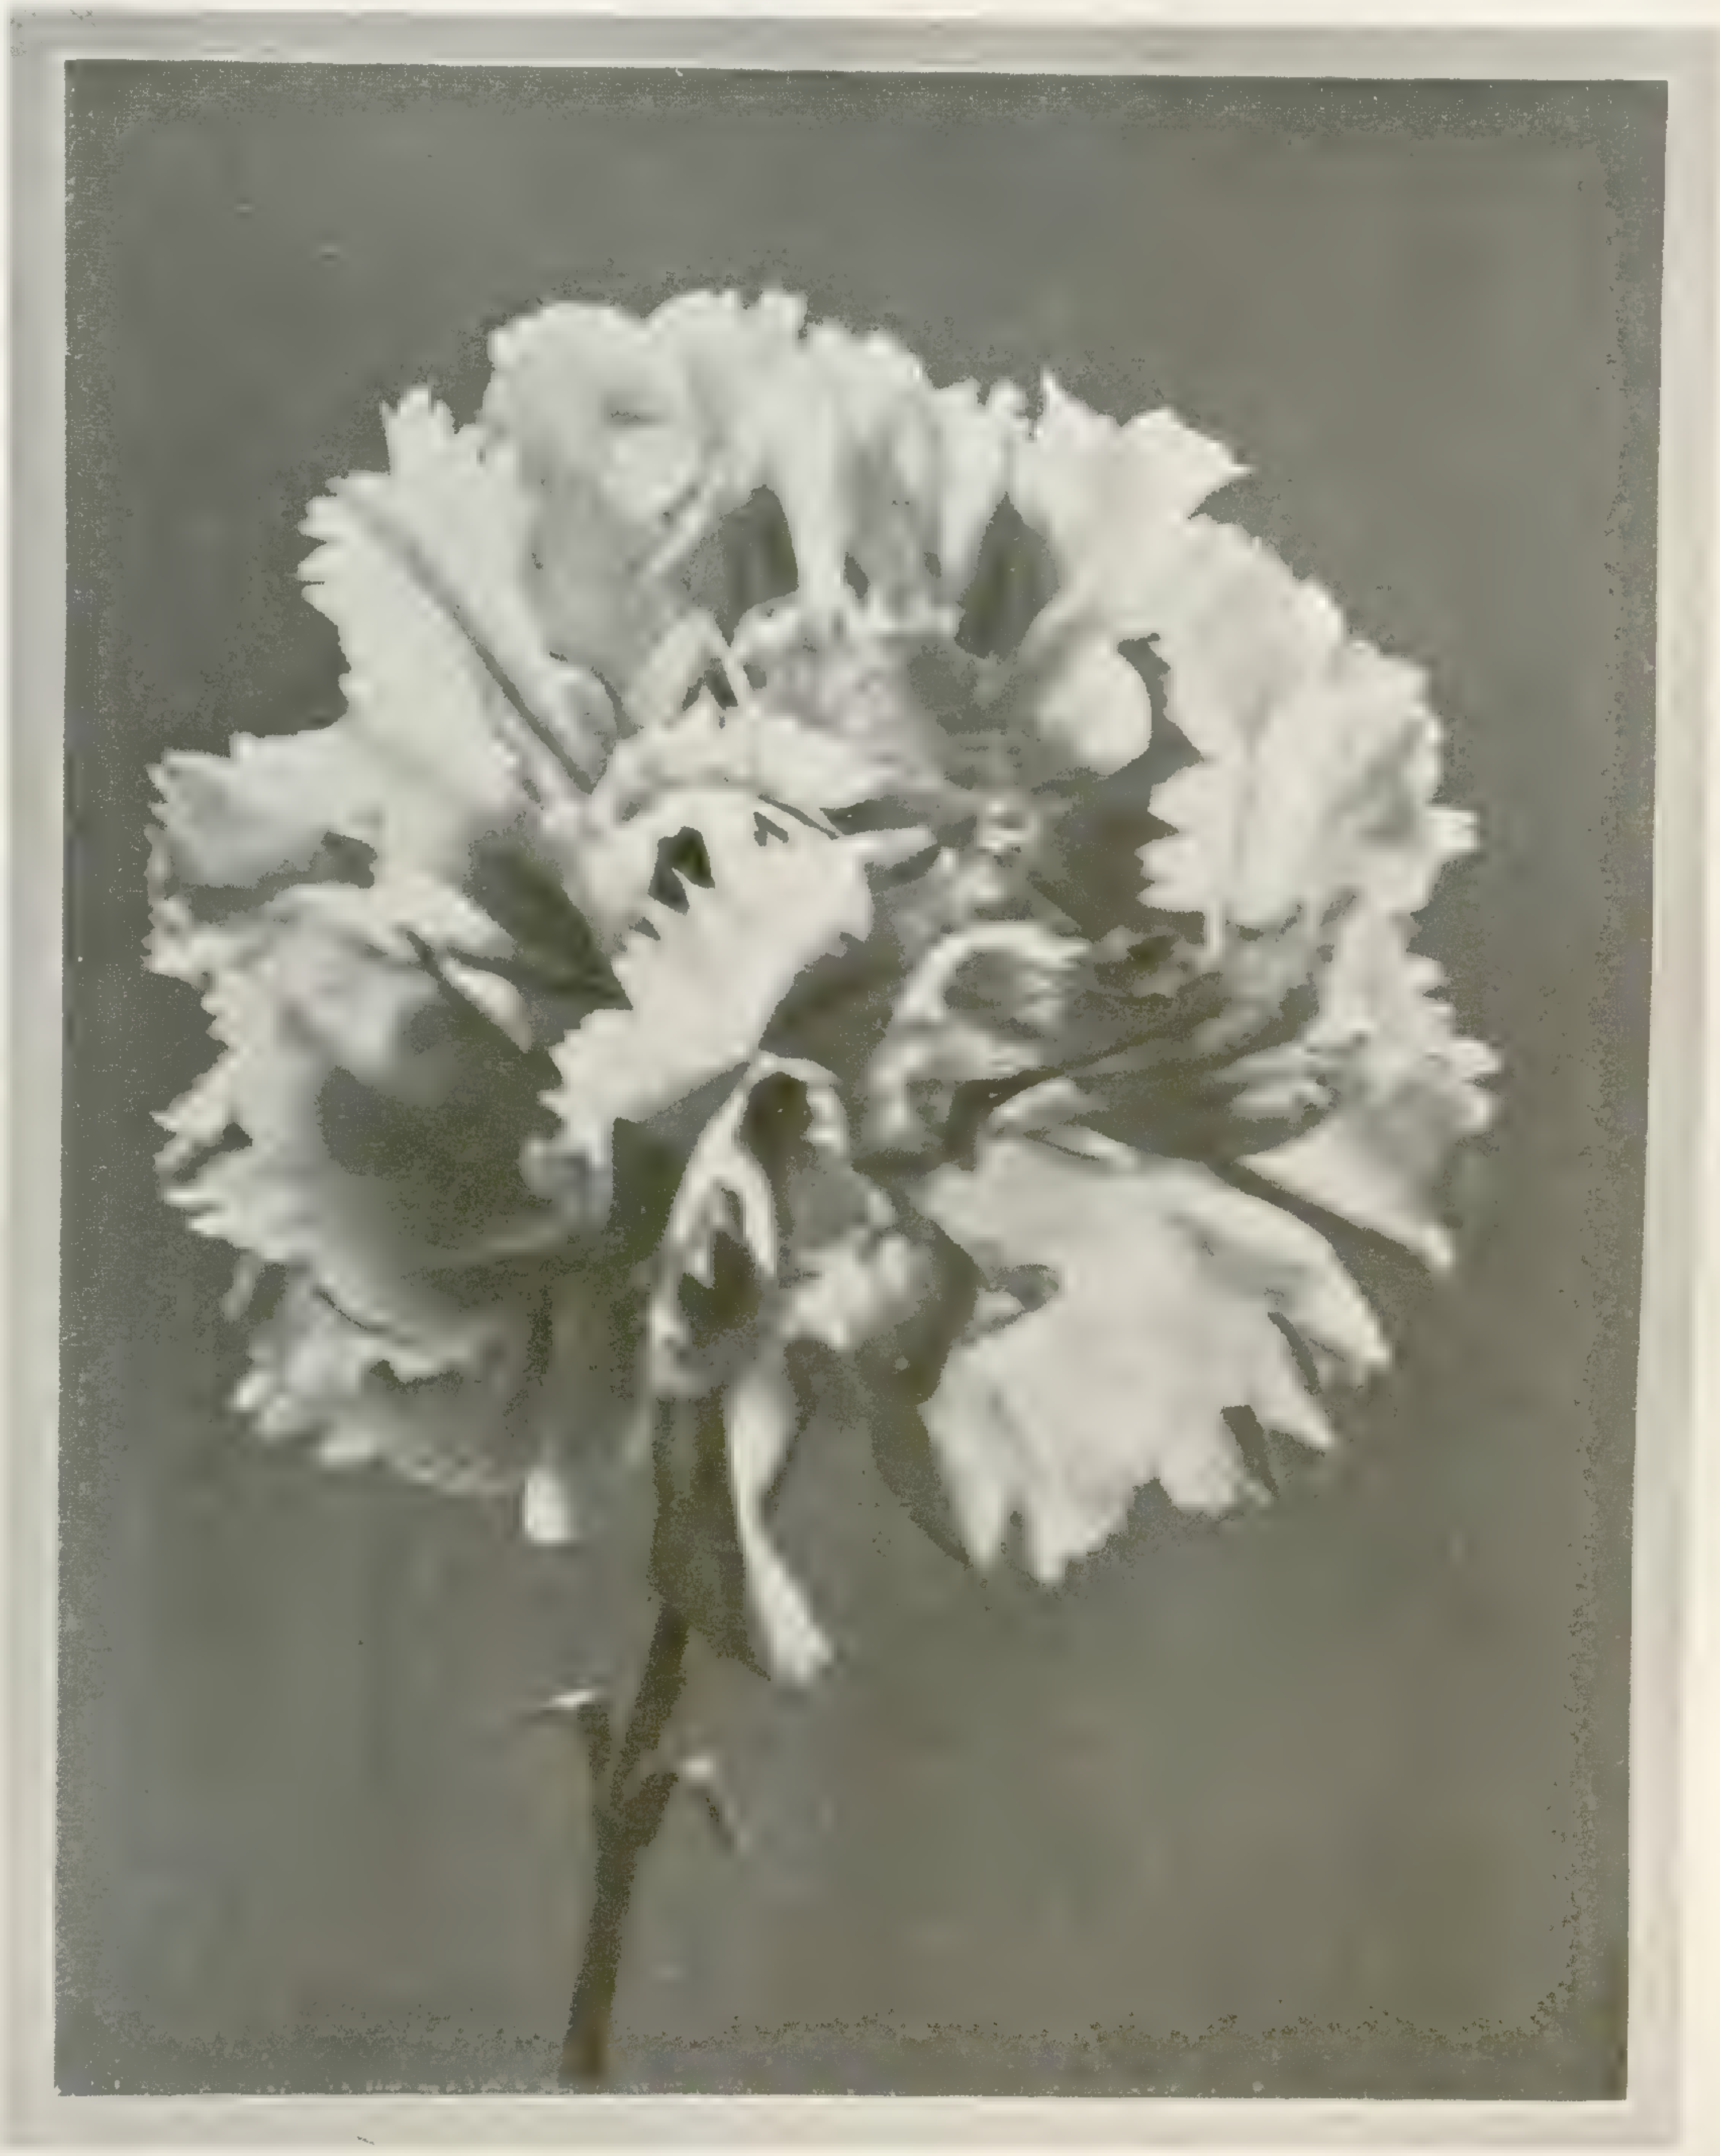
A Musselburgh Gardener Suffocated.—On the afternoon of March 25 the body of Thomas Hogg was discovered in a chair in the little tool-house at the Fever Hospital, Portobello, where he was employed once a week attending to the garden and grounds. Hogg, who lived in Downie Place, Musselburgh, had gone to the hospital as usual on the previous day for his ordinary weekly day's work, and had disappeared. On search being made, it was found that the door of the shed would not open, and, an entrance being made through the window, he was discovered sitting dead in a chair, with a tin of seed potatoes between his knees. It appeared that he had taken a stove into the house to heat it, and, there being no ventilation, had been suffocated.

Boskoop Jubilee Flower Show.—At the great exhibition of forced shrubs and perennials, to be held at Boskoop on April 5 to 16, H.R.H. Prince Henry of the Netherlands is expected to attend the opening ceremony; he has already presented two large medals for competition. His Excellency the Minister of Agriculture will deliver the opening speech. The De Volharding Steamboat Company of Leiden will place a large saloon boat, gratis, at the disposal of the members of the International Jury, officials of the Pomological Society, and the Commissioners of the exhibition, and will make a trip to Rotterdam to inspect the famous harbour works. At Rotterdam the Holland-America Company will entertain the international company at luncheon on one of its large Transatlantic passenger boats.

Sir Joseph Banks' House.—The famous botanist, traveller, and horticulturist, Sir Joseph Banks, after whom one of the Royal Horticultural Society's medals was struck, resided for some years at No. 32, Soho Square, and a tablet notifying such residence has been affixed to the house by the direction of the London County Council.

Dominica Botanic Station.—The work of this important station continues to be carried on with much success. The gardens are maintained in a high degree of efficiency, and the activities during the past year included experiments with spineless limes, grafted cacao, various citrus plants, and Para rubber. According to the annual report Para rubber succeeds admirably in the wet districts of the island, and the lime industry has become well established. About 75,000 economic plants, and large quantities of seed, were distributed during the year.

Alterations in St. James's Park.—The statements that have been made with reference to the construction of a new roadway in St. James's Park, and the building of a stone bridge of a highly ornate character over the ornamental water therein, has given rise to some apprehension and considerable discussion. In the House of Commons on Monday last Mr. Noel Buxton asked Mr. Dudley Ward, as representing the First Commissioner of Works, whether he could give an assurance that no alterations to the width of the bridge across the lake in St. James's Park was in contemplation. In reply, Mr. Dudley Ward said that the statements which had appeared on the subject of the Memorial to King Edward were not authorised by the committee appointed to deal with that matter, and were consequently liable to convey a wrong impression. It is evident that this was the case, for he observed that most of the questions suggested that it is proposed to make a new road and construct a broad bridge across the water in St. James's Park. He had the fullest authority for saying that no proposal to make a roadway and a bridge for vehicular traffic had ever been put forward, much less considered; and could assure the hon. members that the First Commissioner would not for a moment consent to such a scheme, which would be exceedingly detrimental to the amenities of the Park. The suggestion of the Executive Committee was that a statue of King Edward VII. shall be placed on the south side of the Mall, immediately opposite Marlborough Gate; that such rearrangement of the formation of the ground as may be necessary for the surroundings of the statue shall be carried out; and that, in order to give a vista of the statue from the south side of the Park, in Birdcage Walk, a footpath shall be made, which will be carried over the lake on a stone bridge, which will only be of sufficient height to admit of the passage of boats beneath it, and will thus form a distinct improvement upon the present suspension bridge. This suggestion of the Executive Committee was considered by the General Committee at the Mansion House on Monday morning; and, after the misapprehensions caused by the reports had been removed, it was adopted at a full meeting with only four dissentients. The department which he represented would welcome any discussion upon the project, as it could not fail to remove the misapprehensions with which, at present, it appeared to be surrounded. At the meeting of the General Committee of the King Edward Memorial for London held on Monday, the Lord Mayor stated that, in carrying out the proposed scheme, to destroy the rural aspect of the park was never contemplated, and he was assured that in carrying out the scheme only one plane tree would be removed, and that the area of turf would be increased.



PERPETUAL-FLOWERING CARNATION EMPIRE DAY.
Colour, bright pink. A.M., R.H.S., March 28. Raised by Mr. Smith, Enfield Highway, and exhibited by Messrs. R. F. Felton and Son, Hanover Square, W.

Tobacco Culture for Nicotine.—Our contemporary "Farm and Garden" urges that the only reason for growing tobacco in this country would be for the production of nicotine for the use of fruit growers and other horticulturists as an insecticide. It is very valuable for this purpose, but at its present price, 15s. per lb., is out of reach. The possibility of growing tobacco for such a purpose has been the subject of Experiment at the South-Eastern Agricultural College, Wye, and it has been found that nicotine could be produced on the farm at considerably less than the price quoted above. What is wanted now is for the Government to permit fruit growers to cultivate tobacco for this purpose.

R.H.S. Gardens Club.—The annual meeting of this club will be held at the R.H.S. Gardens, Wisley, on Saturday, May 13. Will all members who can possibly attend please communicate at once with the hon. secretary, Mr. R. J. Wallis, Newdigate, Dorking, in order that early arrangements may be made for conveyances and refreshments.

THE QUEEN VICTORIA NIAGARA FALLS PARK SYSTEM.

The following account of the Park system in process of formation at Niagara Falls, in the Dominion of Canada, is part of an interesting communication received at Kew from Mr. H. J. Moore, chief gardener, who was formerly a member of the gardening staff at Kew. The scheme outlined promises to provide the Dominion of Canada with a most important botanical collection of trees, shrubs, and hardy plants, as well as a park system of remarkable beauty, unique in the grandeur of its surroundings. We reprint it, with due acknowledgments, from the "Kew Bulletin."

Many people who have visited the Falls of Niagara associate the name with the cataract only. The district, however, has other claims to fame. In the Niagara peninsula is to be found one of the finest fruit-producing countries in the world. Fruits from this district bring the highest prices, the quality of the peaches, apples, and grapes (outdoor) being unsurpassed. The Niagara district also furnishes much of historical interest, for here were fought some of the bloodiest battles of the fierce conflict of 1812 which has had such an effect upon present-day administration along both sides of the Niagara frontier.

On the Canadian side of the Niagara River, extending about 26 miles, between the villages of Queenston and Bridgeburg, is a strip of land which the Provincial Government of Ontario very wisely purchased and set aside as a national park, the total area of which is just over 800 acres. At one end of this reserve, near Lake Ontario, is the battlefield of Queenston Heights; and at the other end the battlefield of Fort Erie. The city of Niagara Falls, Ontario, is about midway between these two points, and here the Queen Victoria Park Commissioners are doing a splendid work in developing a park system which will undoubtedly rank with the best in the world, both from an æsthetic and an educational standpoint.

Perhaps the most important project the Parks Commission have in hand is the construction of a boulevard extending from a point near the Falls to Bridgeburg 16 miles up the river. I need not enter into details of its construction; suffice it to say that each mile section along its course will be planted with one variety of shade tree, while at several points, where the width is sufficient, small parks will be formed. Along such sections of the boulevard as are somewhat removed from the river, avenues of trees will be planted, but where the river runs parallel with it the trees and shrubs will be grouped in such a manner that they will not obstruct the general view of the river, which is, in many places, over a mile in width.

The park system will undoubtedly be very attractive, enhanced as it is by the beauty of its environment. The proximity of large Canadian and American cities, such as St. Catharine's, Niagara Falls, and Buffalo, renders its construction essential, and in time it will no doubt rank with the best American park systems in point of utility as well as beauty.

The area in the vicinity of the Falls, amounting to two hundred acres, is being transformed and laid out more or less in the nature of a large botanical garden. The southerly portion will form the arboretum. A large range of iron-frame greenhouses and conservatories will be built to accommodate various exotic species and varieties of plants, also to furnish a sufficient space to display the decorative or greenhouse types, such as chrysanthemums, cyclamens, primulas, etc., in their respective seasons.

The northerly portion, in which are situated the herbaceous borders and flower beds, also contains the baseball, football, and cricket grounds, the tennis courts, and bowling greens. In this area many beautiful and valuable specimen trees and shrubs are planted.

Coniferæ are strongly represented, and flourish well under the conditions at the Falls. Thuia occidentalis, Juniperus virginiana, Tsuga canadensis, Pinus Strobus, and Taxus canadensis grow naturally at various points in the park proper, and are also to be found in abundance along the lower Niagara Gorge.

Evergreens other than conifers are rare, very few of the broad-leaved type have up to the present proved hardy enough to stand the rigours of the severe Canadian winters, therefore this class of plants is only represented by such subjects as Rhododendron catawbiense, R. maximum, and Kalmia latifolia.

There are many remarkable specimens of deciduous trees, some of which are growing naturally, while others, perhaps the majority, have been planted. Splendid specimens of Ulmus americana, Æsculus hippocastanum, and Fraxinus americana are to be seen at every turn; Juglans nigra, the Black Walnut, is fairly common, and attains a great height, many specimens in the park are at least 80 feet high.

Catalpa Bungei, C. speciosa, C. bignonoides, Liriodendron tulipifera, Quercus coccinea, Q. palustris, Q. rubra, Tilia europæa, and T. americana are also included among our arboreal specimens. Of the genus Fagus we have three species, namely, F. ferruginea, F. sylvatica, and its variety purpurea.

Nowhere do hardy shrubs flourish better than at Niagara Falls, the spray conditions being such that plant life very rarely suffers from drought, consequently the shrubs are healthy and vigorous, although in the past they have suffered somewhat through lack of proper pruning and thinning; the same is also true of the trees.

Berberis Thunbergi, B. vulgaris, B. aquifolium, and B. canadensis thrive splendidly. Cornus of many species, forsythias, ligustrums, hydrangeas, loniceras, deutzias, including both single and double flowering kinds, such as D. crenata, D. Lemoinei, D. candidissima, D. gracilis, and D. scabra also flourish. There are in addition a few varieties of the above species.

The herbaceous garden has during the past been arranged in the form of a huge border, but steps are being taken to arrange the whole collection botanically after the Kew method. Space forbids a detailed account of the species and varieties of herbaceous plants, but from the fact that the garden covers one acre of ground, the number of plants may be approximately estimated. Liliums, phloxes, and perennial asters flower profusely, each in their respective seasons affording a beautiful sight to the thousands of visitors who annually visit the park.

The proposed arboretum in the southerly portion of the park will be so designed that the trees and shrubs can be planted botanically in groups for educational purposes. There will be a pinetum, an ericaceous garden containing a rhododendron glen, and a collection of lilacs amongst other features. I mention these simply to give the idea of what is contemplated. All trees and shrubs indigenous to temperate North America, and especially to Canada, will be planted in this area, while acclimatised exotic subjects will also be included in the collection.

A better location for an arboretum would be hard to find; on the west the area is flanked by an escarpment 100 feet high covered with beautiful hardwood trees interspersed with a few pines. It is sheltered from violent storms from that quarter, also in some degree from the north, as the escarpment bends round and covers a distance of two and three-quarter miles. At the most southerly point are situated the beautiful Dufferin Islands. The Niagara River borders the entire park system on its eastern side. In both the old and newer portions of the park system the trees and shrubs will be named after the method in vogue in Kew, lead labels being used. One of the objects of the Park Commission is to develop the park system along educational lines, and the Commission and their superintendent, Mr. John H. Jackson, have entered upon the work in the right spirit. What the Ontario Agricultural College is to the province in agriculture, so will the Queen Victoria Park be to the province and to the Dominion of Canada in horticulture and botany. In landscape beauty the park system will undoubtedly rank amongst the best of its kind, for glorious natural features abound on every hand.

There are four power generating stations in the park, the Toronto Power Company's, the Canadian Niagara Power Company's, the International Railroad Company's, and the Ontario Power Company's. The Toronto Power Company's generating station is a magnificent structure, and although it is not quite completed, it has the appearance of a beautiful library or museum. In the immediate foreground are beds sunk in concrete, the whole being arranged in the form of a terrace approached by steps. In these beds are usually planted sub-tropical and ordinary bedding planting plants in spring, and in the autumn bulbous plants, such as tulips, hyacinths, and narcissus.

The Administration Building contains the offices of the Parks Commission and of the superintendent and his staff; the basement is divided into lavatories and constables' headquarters. The second floor serves as a restaurant, while the board-room of the Commission and their bedrooms are on the top or third floor. These rooms are only used when the Board is in session. Standing as it does in proximity to both the American and Canadian Falls, the building has a very desirable location, and from its balconies splendid views can be obtained.

The office staff of the park is composed of the superintendent and his assistant, a landscape gardener, an assistant engineer, and two draughtsmen, an accountant, and assistant stenographer. The number of men employed in the park proper is about 80 in summer, this number being reduced to probably 20 in winter; the greenhouse staff of four men is permanent. The total number of men employed in the entire park system, including the outlying parks and boulevard, is approximately 120. This number of necessity must be greatly increased as the boulevard is extended.

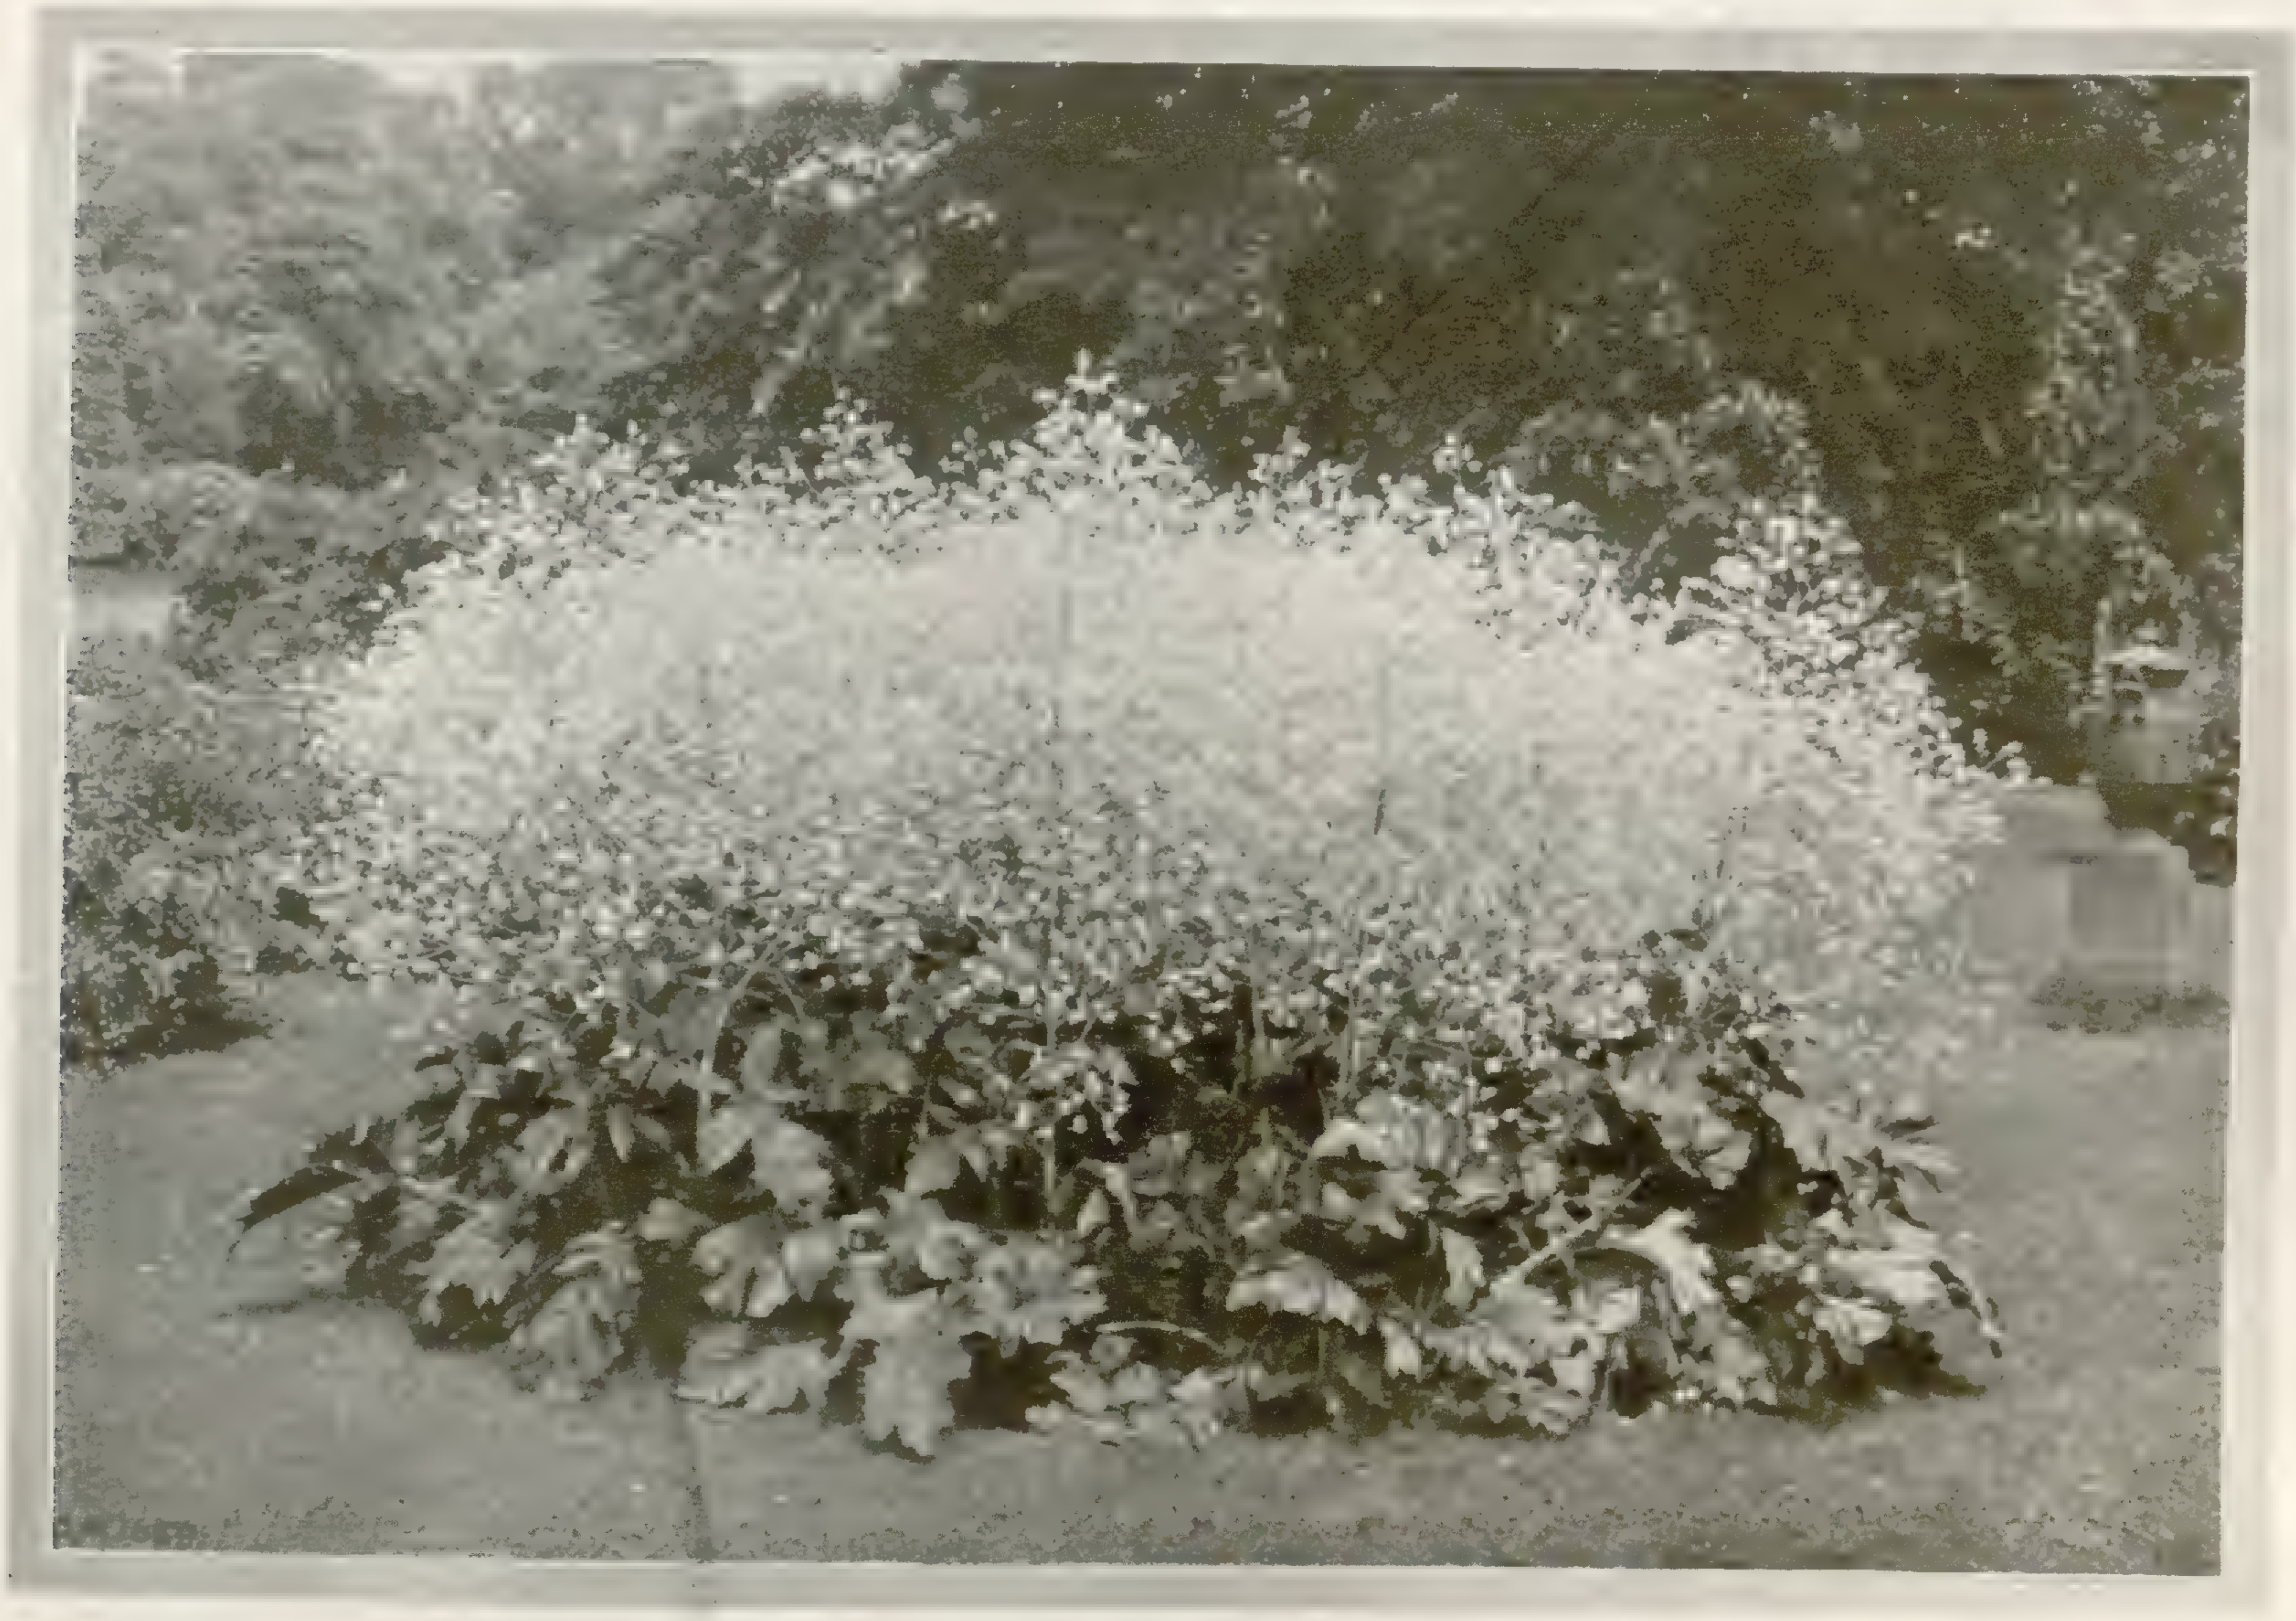
There are only four trained gardeners employed by the Parks Commission, two of them Kew men. I have met many gardeners from Britain, and am glad to say that in nearly every case the best positions are held by old Kewites. I may state that the mere fact of having taken the Kew course places a man in the front rank of horticulturists out here. Let me say that nowhere else is it possible for a gardener to obtain such a training as Kew affords. This fact strikes home to many a Kewite, when Kew to him is a thing of the past.

As an old Kewite I would advise the young fellows in Kew to make the best of their time, not only as far as practical work is concerned, but also in the various courses of lectures. Two years is a very short period, they should therefore crowd all they possibly can into them. The opportunity will never come again, and when they leave they should remember it is their duty wherever they may be to uphold the reputation of Kew. By so doing the chances of their fellow Kewites are materially improved.

Senecio scandens is a welcome addition to climbing shrubs, as it flowers when the majority of this class are over, being at its best from August till October. The flowers are a rich shade of orange-yellow, very freely produced, and are conspicuous at some distance. The plant shows to best advantage when allowed to ramble freely over rough timber, and is effective beside water or grown on poles among other shrubs. It succeeds in ordinary garden soil, provided this is well trenched and manured previous to planting, and, although somewhat slow the first season, growth is extremely rapid once the roots become established. Like the herbaceous members of this genus, the plant under notice is quite hardy in the open.—L. O. V.

CRAMBE ORIENTALIS.

The genus to which the much-appreciated seakale belongs includes several species that are sufficiently attractive to justify their being utilised for beautifying the flower garden and pleasure grounds, and prominent among them is the one herewith illustrated. It has large, deeply lacinated leaves, and elegant, much-branched flower stems, which rise to a height of six or seven feet and bear myriads of fine white flowers. The effect it is capable of producing when grown under conditions favourable to the full development of leafage and flowers is so well shown in the accompanying illustration that there is no occasion to refer otherwise than briefly to its usefulness for enhancing the attractions of the pleasure grounds, and especially those parts that are maintained in a semi-wild state. The Eastern "kale" is highly effective when arranged in a bold group, as at Kew, but in private gardens, where it is desirable that the whole of the beds should be more or less attractive throughout the summer months, the preferable course is to arrange it in groups of moderate size in mixed borders, and thus avoid any appreciable gaps after the plants have yielded of their floral tribute. As in the case of the seakale, this stately species should have a liberally enriched and deeply stirred soil, and plants that have occupied their positions for some time should annually have a rich top-dressing in the course of the winter or early in the spring. C. cordifolia is also highly ornamental, and well deserving of cultivation; C. orientalis, Jacq. is now referred to as C. pinnatifida, and, as in the case of the last-named, is well worth growing where space is available for hardy herbaceous plants of robust habit. When occupying beds C. orientalis may have daffodils and gladioli associated with them for prolonging the attractions of the beds.



CRAMBE ORIENTALIS AS GROWN AT KEW.
A handsome species with white flowers, and possessing much value for the less highly-dressed parts of the pleasure grounds.

NOTES FROM KEW.

Arctotis aureola.

A good deal of confusion exists with regard to the nomenclature of the different species of arctotis, another name for this being A. aspera. In the "Kew Hand List" this last-mentioned name is given as the correct one, but in the greenhouse at the present time several flowering examples have the name of A. aureola applied to them. Whatever is the real name, it is certainly a very beautiful subject for the embellishment of the greenhouse at this season, and not this season alone, for it will continue to bloom for months together. It is a plant of a fairly woody nature, and will flower well when from eighteen inches to four feet in height, or even taller than that. The pinnate leaves are from six to eight inches long, and are covered with a silky white tomentum, more pronounced on the lower than on the upper surface. The composite flowers are a good deal in the way of a single chrysanthemum, and are from three to four inches in diameter, the ray florets being of a rich orange-yellow colour, and the disc dark tinted. In a small mass or group this arctotis is seen to considerable advantage. Another form also in flower in the same structure used to be known as Arctotis aspera arborescens. This is less effective than the preceding, the flowers being of a creamy-white colour with a slight purplish tinge on the reverse of the petals. The different members of the genus are natives of South Africa, and, like the pelargoniums which come from the same region, they are essentially sun lovers. The same kind of potting compost, too, will suit both classes of plants.

Cinerarias.

These contribute largely to the embellishment of the greenhouse, and a vast number of different forms are therein represented. A notable feature is the comparative absence of the massive-flowered florists' varieties, which used at one time to be grown to the exclusion of all others. Now those of a lighter and a looser habit are preferred. The variety Matador, which last season aroused in many places a good deal of interest by reason of its distinct shade of red, stands out in its colouring quite away from any of the others.

Anoiganthus breviflorus.

This South African bulbous plant is quite distinct, and possesses the merit of readily conforming to pot culture. It is not often met with, though flowering examples have been noted at Kew for years, and not always at this season of the year. Just now it is in bloom in the cool portion of the T range. From a firm oval-shaped bulb strap-shaped leaves are pushed up to a height of a foot or a little more, and the flower scapes are often rather shorter than the foliage. They are terminated by a loose umbel of flowers, which individually are about a couple of inches in length and funnel-shaped, their colour being rich yellow. Even when fully expanded the flower presents the appearance of being only partially opened. This anoiganthus needs to be freely supplied with water when growing, but during the dormant period it should be kept almost dry. An ordinary greenhouse temperature is all it needs.

Thyrsacanthus rutilans.

This is an old and well-known plant, but at the same time it makes such a goodly show in the intermediate portion of the T range that it merits at least a passing notice. Unlike many decorative subjects, this thyrsacanthus is seen at the best advantage in the shape of leggy specimens, as then the long pendulous racemes display the scarlet-crimson tubular-shaped blossoms to the fullest extent. This thyrsacanthus belongs to the order Acanthaceæ, and is, therefore, a near ally of the aphelandras, eranthemums, jacobinias, and justicias.

Eupatorium Raffilli.

Some well-flowered specimens of this eupatorium in the intermediate portion of the T range serve to show what a valuable subject it is for decorative purposes at this season. At the same time, though difficult to say without actual comparison, it appears to me very little, if at all, removed from the form which was commonly grown some years ago under the name of Hebeclinium atro-rubens. The genus Hebeclinium is now merged into that of eupatorium, the well known species formerly called H. ianthinum being now Eupatorium ianthinum.

Medinilla magnifica.

A good form of this grand flowering stove plant in the Victoria House is bearing a number of its drooping panicles of clear rose-coloured blossoms. It is justly entitled to be regarded as one of the finest stove plants we have, and in the days when large specimen plants were grown and frequently exhibited it was very popular. This medinilla was found in Manila by Thomas Lobb, when travelling in the Malayan Archipelago on behalf of Messrs. Veitch, in whose nursery in Exeter it first flowered in April, 1850.

Begonia scabrida.

The "Dictionary of Gardening" gives the date of the introduction of this begonia from Venezuela as 1857, but notwithstanding the fact that it is a very desirable species, one rarely meets with it in gardens. In the T range it is just now flowering freely. It is of rather erect growth, clothed with roughened bright green leaves, and bears a great profusion of white flowers.

Nuttallia cerasiformis.

Although this shrub is frequently mentioned in horticultural publications, it is really planted to a very limited extent. It certainly merits further recognition, and some good examples just now at their best in Kew show this shrub in a very favourable light. It forms a dense-growing mass or clump, usually about six feet in height, and the flower racemes, upon which its beauty depends, are drooping, in a manner somewhat suggestive of those of the flowering currant, but white in colour.

Ceanothus rigidus.

The fact that this ceanothus, if protected by a wall, blooms at about the same time as our early-flowering shrubs, is too often overlooked. It is a stiff-growing kind, whose woolly branches are clothed with small, firm-textured leaves. The purplish-lilac flowers are disposed in little clusters, and borne in great profusion in the spring months. As illustrating its early-flowering qualities, it may be noted that a specimen trained to the wall of the herbaceous ground had a few of its blossoms expanded in the middle of March.

K.

A FINE BEETROOT—SUTTON'S BLACK.

BEETROOT.

To ensure perfect specimens of medium-sized high-class beet it will be found necessary on most lands to bore deep holes and fill these in with fine soil which has been sifted, such as old material collected from the potting shed. This soil should be made moderately firm, and the seed not sown too early—a mistake frequently made. The first or second week in May will be quite early enough. Two or three seeds should be sown at each station, and covered to the depth of about a quarter of an inch; thin the seedlings to one at each hole, when large enough. Except for keeping the ground constantly stirred little other attention will be needed until the time for lifting, which should be done immediately the roots are large enough, and, if stored in the usual way, these will keep sound and good until the following year. Care should be taken when lifting the crop not to break the tap roots.

Good and reliable varieties are Dell's Blood Red, Pragnell's Exhibition, Sutton's Black, and Delicacy.

E. Beckett, V.M.H.

HAMAMELIS AND CORNUS.

In these days of interesting and beautiful gardens, is it not rather surprising that plants of Hamamelis or Witch-hazel so rarely find a place among our flowering trees and shrubs? A specimen witch-hazel is very seldom seen, and yet the shrub has many claims of merit to a position in every collection. Its period of blooming—the winter months—and beautiful and quaint flowers, with a charm of their own, commend it for interest, use, and ornament in the pleasure ground. In a cut state it stands well, resembling an odontoglossum, with the parts of the flower cut into segments. It is not particular as to soil, but prefers a moist sandy loam. There are several kinds of witch-hazels, all of which are well deserving of a sheltered corner in a shrubbery. H. mollis is, perhaps, the best, but H. virginica, H. japonica, and H. arborea will also be found useful, effective flowering subjects for winter decoration, and render their position both ornamental and attractive in January and February.

The Cornelian Cherry (Cornus mas) is an old-world plant, which seems to have been lost sight of, or to have lost favour with the present-day planters, as only an odd specimen is met with in the country, and that at some long-established place. It, too, blooms at a time when outdoor flowers are scarce, and forms a very conspicuous object in a shrubbery or margin of a wood. It also fruits freely, and, at one time, the berries were used for tarts. Evidently better things are now available for this purpose, otherwise more cornus would be found in cultivation. Apart from this, however, its greenish-yellow blossoms in March and April give life and beauty to the landscape, mark the coming floral year, and win for itself a claim to be included in all collections of flowering trees and shrubs. It is not fastidious as to soil, but luxuriates in a medium inclined to be heavy and moist, and in this attains a height of something like 20ft.

Both of these neglected shrubs are much more valuable decorative subjects for our pleasure gardens than many species employed in their embellishment at the present time, and, flowering when all else around them is dormant, in keen, cold winds and snow, their value cannot be too highly estimated.

X. Y. Z.

DWARF POLYANTHA ROSES.

The extreme beauty and general usefulness of the dwarfer-growing Polyantha or Multiflora roses cannot well be overestimated. We do not obtain the size and substance found in other classes, but many varieties have perfectly-shaped blossoms, and these are borne in immense trusses, which not only make a good show at once, but continue for a long time. They are also the most perpetual bloomers we have, and certainly the easiest of all to cultivate, there being no necessity for elaborate preparation of beds, staking, tying, and the numerous other work needed to get the "show" roses to perfection. In pruning, too, the work is very simple and consists of merely thinning out some of the centre growths and lightly "tipping" the remainder.

As bedders, very few subjects can surpass them, notwithstanding the immense number of beautiful subjects now available. We have to look down at these beautiful little roses, and thus the whole of their beauty is revealed, and the centres of some are perfect and very pleasing. The roses lend themselves equally well to short standard culture, and, though not often seen in this form, I venture to say that "once grown always grown," applies here. Imagine a bushy and well-flowered plant of Mrs. W. H. Cutbush, Etoile d'Or, Aschenbrodel, Aennchen Muller, Katherine Zeimet, or the newer and very deeply coloured Jessie, raised upon a one and a-half to two feet stem. They far surpass many other varieties grown as half-standards. They flower from June until October, and are so dwarf and sturdy that inclement weather has not the same disastrous effect as in the case of roses of larger growth, and in any case, there are far more buds to open upon each truss, which cannot be said of our larger roses.

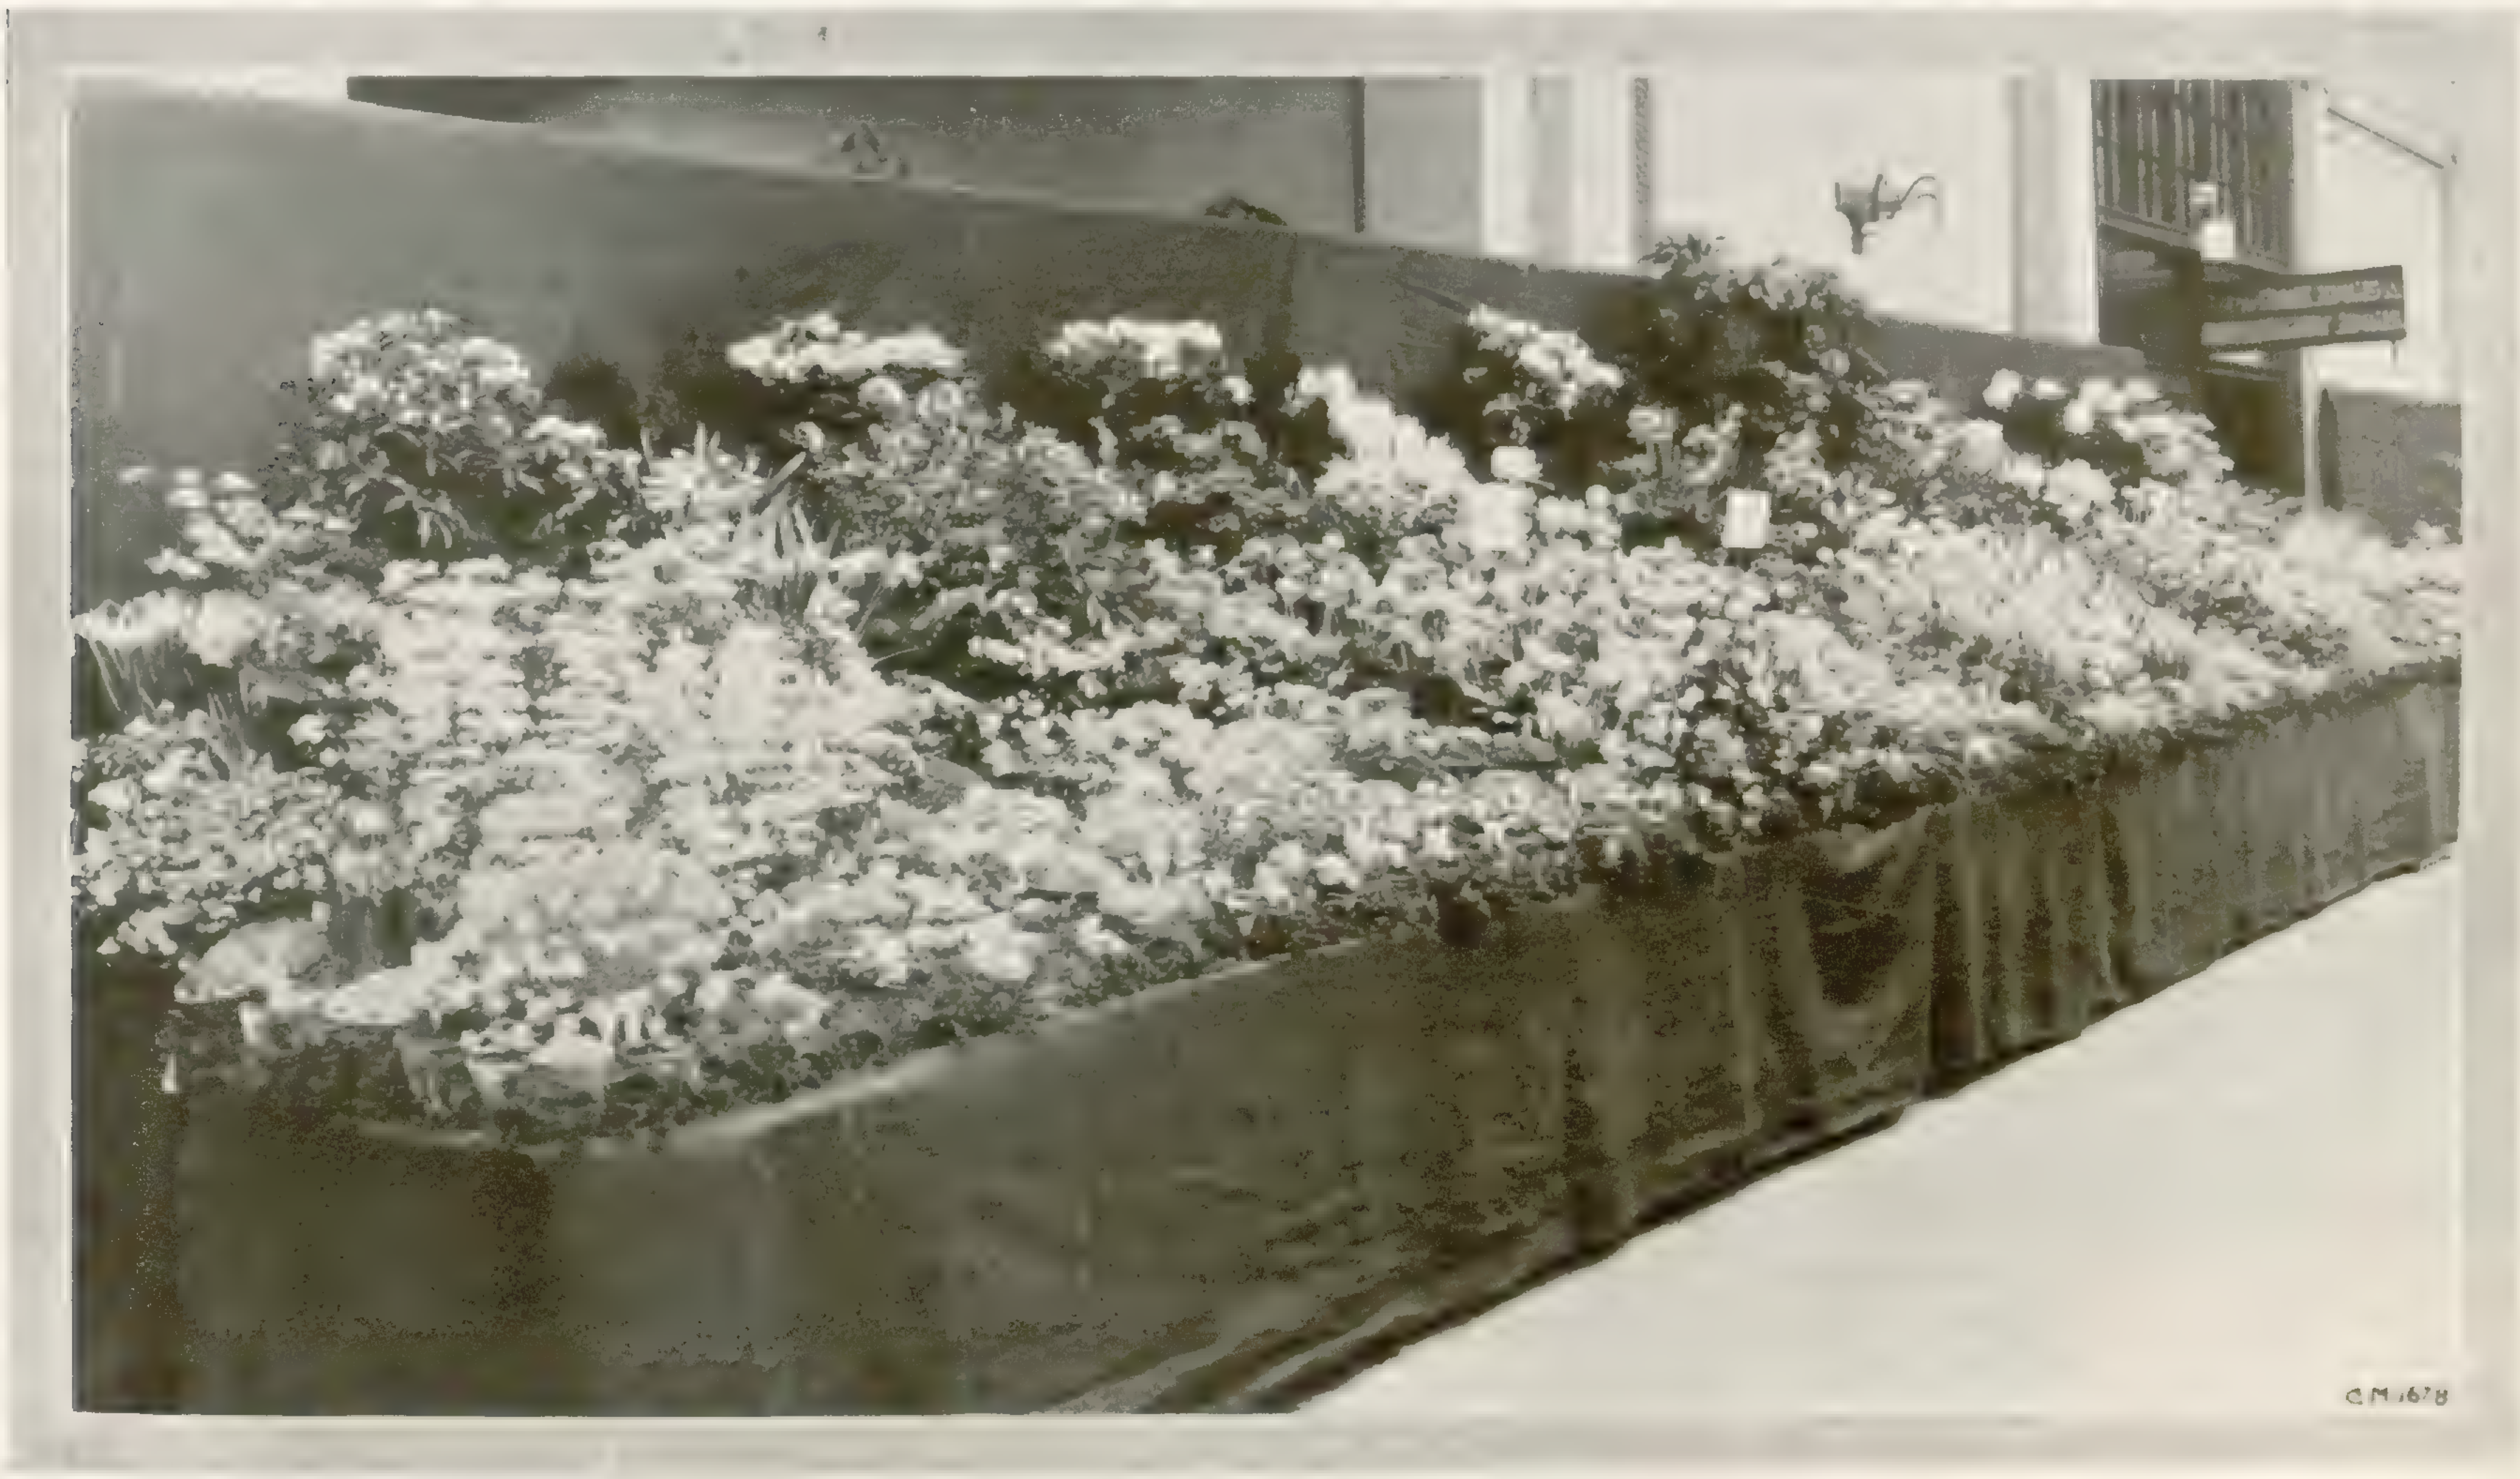
Not only are dwarf Polyantha roses unsurpassed as bedders, and to edge other masses of roses, but we have few more suited for pot culture, while they are much more easily managed than the majority of teas and hybrid teas, never failing to flower. Their large trusses and compact habit render them very useful as decorative roses in pots. True, they are not of much service to cut from, except it be as coat flowers; but they last longer and are more certain than the large flowers generally grown. They possess yet another advantage; they not only force well, but, if afforded a little aftercare when the valuable early crop is over, they will give a second display within six weeks. After the plants have been in pots for a couple of seasons, we find it better to turn them out as soon as the first crop of the season has been realised. The plants then make good growth and flower again during late summer and autumn.

This section yields a large range of colours now; perhaps the best pure whites are Katherine Zeimet, White Pet, Flocon de Neige, and Schneewittchen; blush white, Aschenbrodel, Mignonette, and Gloire des Polyanthas; deep rose, Orleans Rose, Aennchen Muller, Primula, Mrs. W. H. Cutbush, and Phyllis; yellow and orange, Perle d'Or, Canarienvogel, Etoile d'Or, Eugenie Lamesch, and Perle d'Or; deep red, Perle des Rouges and Jessie.

In Kleiner Alfred we have a plant seldom exceeding a foot in height when well established. This is grand when massed thickly, and very showy in quite small pots; red on the outside, suffused with ochre-yellow. Leonie Lamesch is also peculiar, with its bright coppery-red hue, shaded with yellow; the flowers are not borne in trusses so much as the others; indeed, they are generally produced singly, but are very lasting and always accompanied by green and shining foliage. Jessie and Orleans Rose are the only two newer varieties I can speak of from experience, and they are of much value. A. P.

A BEAUTIFUL EXHIBIT OF ALPINES.

There is at the present time a great and growing love for alpine plants, especially for those kinds that may be grown in our gardens with a fair amount of success. This love has led many people to slightly anticipate the spring display in the rock garden by growing a collection of early-flowering kinds and varieties in cold frames, or in a quite cold house. That charming results can be obtained in this way has been amply demonstrated at Kew, where the Alpine House has for very many years been a great source of pleasure during the early months of the year. Exactly how the fine collection of alpines grown in pots and pans by Mr. Grandfield, gardener to Sir Everard Hambro, at Hayes Place, Hayes, is housed we do not know, but we imagine that little beyond protection from rain and snow and the severest frosts is all that is provided. Anyhow, the exhibit staged at the meeting of the Royal Horticultural Society on March 14 was a delightful one, and by its extent and beauty it attracted a vast amount of attention from the visitors, and received a rare meed of praise. As already referred to in these pages, the primulas and saxifrages were mostly in evidence, and they were represented by finely developed specimens. It is not too much to say that this splendid exhibit, to which a gold medal was awarded, did a very great deal to further popularise alpine plants and flowers.



A BEAUTIFUL GROUP OF ALPINES.
Staged at the R.H.S. Meeting on March 14, by Mr. Grandfield, gardener to Sir Everard Hambro, Hayes Place, Hayes, Kent.
A Gold Medal was awarded.

Early Melons.—These will now require much care and attention. Carefully tie in the growths as becomes necessary, and as soon as three or four female flowers are ready they should be pollinated, preferably about the middle of the day. Do not set any till there are sufficient for the crop. Two or three good fruits will be enough on cordon plants, and, as far as practicable, let them all swell away at once. Admit a little air on all balmy days.—W. A. Cook.

CORNWALL COUNTY FRUIT PLOT.

The Cornwall County Council has established an experimental fruit plot at Gulval, near Penzance, for the benefit of market gardeners and smallholders. The plot is not worked solely for financial profit, but chiefly for educational purposes. The grounds are open every working day of the year to anyone requiring information on fruit culture and kindred subjects, and Mr. W. Avis, the head gardener, is instructed by the Council to also deal with questions asked through the post by those who are unable to visit the plot, and needless to say many take this opportunity of obtaining information on the numerous subjects relating to horticulture.

When the Council took charge of the grounds, four years ago, everything was in a backward state, the progress made since that time, however, is an object-lesson for all horticulturists. Every spring a report is issued, stating what progress is being made, and valuable hints are given for the benefit of those who earn their living on the soil. The following account of the various experiments, and the amounts realised from the sale of the produce, will be of interest to your readers.

Apples and Pears.

There are 150 apple trees at the plot, planted 13 years ago, and if there were no vacancies they would cover a half acre of ground. The varieties which produce the best results are Bramley's Seedling, Bismarck, Newton Wonder, Golden Spire, Lord Grosvenor, Beauty of Bath, American Mother, Allington Pippin, Worcester Pearmain, and Lord Derby. Last year the crops realised about £50. A few gooseberries are grown among the trees, but these are being diminished each year. The net returns from the gooseberries was £9. The pear crop was almost a failure, owing to the heavy crop of the previous year, and to the very unfavourable weather while the trees were in flower; in spite of this the average returns for the past two years works out at £75 per acre.

Experimental Salad and Early Vegetable Department.

In this department the past year was a highly successful one, the net returns being £152, compared with £102 in the previous year. With the aid of frames and handlights, which cover about 14 perches of ground, a net return of £47 was realised. Most of the produce was sold to local tradesmen, and the demand was greater than the supply. The crops raised were radish, lettuce, carrots, cauliflowers, marrows, cucumbers, melons, tomatoes, and celery. In the intensive culture garden, after deducting cost of manure and labour, there was a clear profit of £1 9s. 9d. per perch, equal to £238 per acre. Forty perches were devoted to outside intensive culture, and there was a fairly good year in such things as endive, Cos lettuce, broad beans, cauliflowers, early carrots, etc., the bulk of these being sent to London from February to the end of June, after which it was of no use sending to London; the net returns from endive, Cos lettuce, and broad beans were £47.

Methods of Culture.

The endive and lettuce were planted in rows one foot apart, every fourth row being missed. In November broad beans were planted in the vacant rows; the ground was all clear of these crops by the end of June, the beans, of course, being the last. The ground was then planted with cauliflower and broccoli for local trade. Early out-door carrots is a line that any market gardener with early ground might take up, and it would pay him well for his labour. Early Shorthorn carrots were sown on the plot on March 1, and they were pulled on June 1, at 1s. 6d. per doz. bunches; Covent Garden, or any other large market, would take large quantities at this time. Some were sent to Covent Garden from the plot as late as June 16, and they sold at 3s. per doz. bunches of about twelve small carrots in a bunch; these were sown on a south border measuring 26 by 7 yards, and gave a net return of £6 10s. French beans proved another good line; Canadian Wonder was the variety, and seeds were sown in cold frames on April 18, transplanted (three plants to a clump) in four rows, 34 yards long, the first week in May, and covered with hand lights for about a fortnight. The beans were ready for picking on June 27, and sold at 8d. per lb. from that date to August 9. These four rows produced a net return of £3 11s. 8d. Scarlet Runner beans were treated in the same way, and were ready for picking on July 15; they were not covered. Two rows produced £2 7s. 4d. The total returns for the year in this department were £214, as against £191 for 1909.

Broccoli.

Varieties were grown for trial. Two proved of special merit, viz., Watkins and Simpson's Early Feltham, a splendid January and February broccoli; and Sutton's Satisfaction, a February and March broccoli; both of these varieties have large firm white heads, well protected, and stand a long time without flying open. Experiments are being made with two new broccolis, and potatoes are being grown for trial purposes this year.

T. H. Rogers.

PEAR PITMASTON DUCHESS.

In a large garden where the soil was light but deep, this variety grew as freely as willows, and matured immense crops four years out of five. In various positions in the garden the trees, both pyramids and those trained on walls, bore exceptionally well. Cultivators who have to deal with small gardens, where the soil is light, should grow this variety worked on the quince stock.

I had a row of pear trees trained as pyramids in the garden referred to, and during the ten years I had charge of them they bore exceptionally heavy crops, and it was necessary to prop up the branches, and even then the weight of the fruit caused some to break off. A gentleman called to see me when on his way back from the Channel Islands, and he said he had never seen such grand crops of pears, and went repeatedly to look at the trees. The crop that year was the best I had had, and the gentleman was so impressed that he determined to plant many trees in his own garden. All were growing on the quince stock, and, with the exception of two specimens, all made satisfactory growth, and required moderate pruning.

The trees occupied a very warm, sheltered position, the branches were long, sturdy, and well apart; consequently, fruits were freely borne on the lower, or basal part of the branches as well as near the ends. Every autumn a heavy dressing of rotted manure was lightly forked under the surface soil, and applications of diluted manure followed, and while the fruits were swelling freely liquid manure was poured into the soil. I had nothing like such good success with trees generally growing in the lower portion of the garden, where the soil was always very moist and rather cold.

G. B.

RHUBARB.

Few crops in the garden are usually more neglected than rhubarb; the most attention it receives, as a rule, being a top-dressing of stable manure some time between the autumn and the spring. The plants are left in the same place for fifteen or twenty years, even more, while the varieties grown usually leave much to be desired. It is true that by reason of the size of its leaves it will appear to thrive under almost any treatment, and will produce a certain quantity of sticks, but when properly managed the same amount may be obtained from a smaller bed, and that of much finer quality. As a general rule we do not need to grow late kinds, as the main recommendation of rhubarb is its earliness, and we seldom use it much after gooseberries come in. Neither do we want green-stalked kinds, as their appearance on the table is not so nice as that of the red sorts. If we believe in growing the best or nothing, some of us will do away with our old plantations and get fresh plants altogether.

Rhubarb is a very deep rooter, and as it has to occupy the ground for a number of years the site chosen for a plantation should be dug to a depth of three feet, and both animal manure and lasting substances like bone dust or quarter-inch bones well mixed with the whole depth of soil. Of the bone material twelve or fifteen pounds to the forty square yards is not too much to use, looking to future results and the length of time the plants will have to feed upon it. Rhubarb may be planted at any time from September to April, but the early autumn is the best time, and, next to that, March. It will grow in any aspect, in the open or under trees, but as earliness is important, some at least should be put on an early border. Four feet should be allowed between the plants, and even five feet will not be excessive ultimately. If it is intended to remove crowns for forcing, they may be put in two or two and a-half feet apart, and alternate ones taken up two or three years after planting. If the plants for the new bed are to be taken from one's old stock it is not necessary to take up the old stools and divide them, thereby getting nothing from both old plants and new for one season, but pieces may be cut off the old stocks with a spade, or chisel and a hammer, each piece of root with a crown to it making a plant, and the bigger the piece of root which can be removed with it the sooner it will become established.

In the treatment of an established plantation there is one principle to be borne in mind, and that is, we are always preparing for a year ahead. It is the strong and well-developed leaves of the summer which, if the plants are properly fed, will store up plant food in the roots for making large succulent leaf stalks early the following spring. There is nothing better than an annual top-dressing of farmyard manure, and the best time to apply it is in February or early March, for if applied in the autumn much of its soluble nutrients may be washed away beyond the reach of the roots before the growing season comes. But this dressing is not sufficient for securing the best results.

The experiments at Hadlow show that when rhubarb was manured with fifty loads of London dung per acre every year, and nothing else, the crop averaged thirty tons a year, while a plot manured with half this quantity of dung, supplemented with four cwt. each of nitrate of soda and superphosphate of lime, averaged forty tons per acre, the cost in the former case being estimated at £10 per acre, and in the latter £7 10s. Reducing these mineral constituents to the level of the garden, we may apply four pounds of superphosphate to forty square yards, and a pound of nitrate of soda to the same area four times during the growing season. On most soils, after a crop has been growing for several years, it will be benefited by the addition of four pounds of kainit to the same area in the winter, while if the soil is deficient in lime basic slag should be substituted for the superphosphate at the same rate, though six pounds, instead of four, will be better. In garden practice, in fact, the quantities of all the above may be increased from 25 to 50 per cent.

Of varieties we do not need many. Hawke's Champagne is, perhaps, the best, being early, of good flavour, and of fine quality. The same three qualities belong to Johnston's St. Martin and Kershaw's Early Paragon, and though perhaps in flavour they are not equal to the first-named, they are stronger in growth and more prolific, especially Early Paragon, which rarely, if ever, runs to seed. St. Martin does not require so much sugar as some, which may be a consideration on grounds of health, if not of economy. Prince Albert (syn. Early Albert) is also a good early variety, and is one of the best kinds for forcing, it being stated to require less heat than most kinds. Victoria is famous for the quantity and size of the sticks produced, but it is rather a market sort than a choice variety for the earliest supplies.

In the matter of forcing, it is not necessary for moderate earliness to lift the crowns and put them in a house, but it is better for the plants, and gives less trouble, to put large pots, half casks, deep boxes, or large drain pipes over them, and pile round them heaps of stable manure to generate heat. Rhubarb has a decidedly better flavour if it is not too much blanched.

Alger Petts.

PERPETUAL CARNATION "CAROLA."

On several occasions of late I have been asked my opinion regarding the merits of this carnation, and I have no hesitation in at once saying that it is by far the finest crimson variety yet introduced. The plant is of vigorous growth, breaking freely when stopped as a cutting, or, on the older plants, after the flowers have been cut. It is one of the easiest of carnations to propagate, the cuttings rooting quite readily. My experience of last season teaches me that when the plants are stood outside in the summer, it is advisable to erect a portable structure over them, on which frame lights may be placed in case of excessive rains; or, where the space is available, they should be grown in a cool, airy house, throughout the whole season.

The good qualities which this variety possesses far outweigh its few faults. Its one and only fault lies in the splitting of the calyx, but little else can be expected when the size of the bloom is considered. This fault is amply compensated for by the flowers themselves. They are freely borne on long stiff stems, and are of a most beautiful velvety crimson, while the scent is exquisite. In size of bloom Carola has no equal as a perpetual variety.

Last year we grew nearly one hundred plants, and this year we have increased our stock to over five hundred, a fact which should speak for itself. Whatever reward Mr. Engelmann, of Saffron Walden, has received for introducing this most splendid variety, it cannot have been too much. Carola might have been, with justification, named "Incomparable."

A. Grubb.

HARDY CYCLAMENS.

My hardy cyclamens have done so well this year that I am tempted to send you a couple of photographs recently taken, one of which I hope you may be able to reproduce.

Possibly the damp sunless summer of last year suited the corms, followed as it has been by a mild winter. Whatever the cause may have been, the plants have bloomed extraordinarily well; the colours have been, and are still, most brilliant, especially those of the crimson form of C. Atkinsi, and the bed, as seen from the house, is really very beautiful. I wish I could have taken a photograph in colours when the flowers were probably at their best. It is a matter of astonishment and regret to me that so few gardeners really "go in" for these delightful and easily grown plants. Their requirements are most modest, and with a judicious assortment of the spring and autumn flowering species it is possible to keep up an almost constant display of bloom.

HARDY CYCLAMEN IN THE GARDEN OF THE ELMS, YALDING.

I think I may safely say that they will succeed in any garden if the following points be attended to: (i.) Partial or "semi" shade, enough only to moderate the rays of the midday and afternoon summer sun: (ii.) a fairly deep layer, say 9 to 12 inches thick, of good leaf-mould, well mixed with a little old lime rubbish, which should not be dug into the existing soil, but merely laid over the surface; (iii.) the corms to be planted in summer or early autumn, according to time of flowering, originally placed at a depth of 2 inches, and gently pressed down and covered, a handful of sharp sand or grit both above and below the larger ones; (iv.) water to be freely given with a syringe or rose during abnormally hot and dry weather; and (v.) the bed to be kept free from weeds.

A northerly or easterly aspect seems to suit cyclamens best, but my experience of a good many years shows that they do not much mind exposure to high winds. I used to shelter mine from the "north-easters" with green boughs, but have long since given that up. It is better, doubtless, to keep the site free from weeds, but the cyclamen is a sturdy little chap, and in the mêlée of a gigantic struggle for existence with even tall-growing undesirables, I will back him to hold his own and come out "on top." Some seedlings of mine that rashly elected to start life in the heart of a clump of Erica carnea invariably push both leaves and flowers right through, and overtop the heath with a splendidly audacious display of marbled leaves and captivating little flowers.

I grow a few odd plants of other flowers among my pets, but remove them if they become aggressive. And as the cyclamens seed themselves everywhere, often migrating several yards to adjoining beds, I do my best to encourage them by carefully removing the grass and poppies, and various forms of cress that infest my garden everywhere, so as to leave all possible space for additional seedlings.

As to the sorts to grow, I do not think it possible to start a cyclamen bed without a fairly good supply of C. Coum, C. Atkinsi, C. repandum, and C. europæum, with a few C. libanoticum, C. neapolitanum, and C. africanum, but a first attempt might well be made with a small collection of C. Atkinsi (or C. Coum), and C. europæum; the pink, red, or crimson-flowered plants should form the majority, an occasional white form being judiciously introduced. It seems to me that my species have hopelessly interbred and hybridised, and have made "confusion worse confounded," so that what was at all times a difficult genus to diagnose has in my case become absolutely an impossible one. But all are beautiful, and flower just as well without long compound names attached to them, so I thin them out as little as I dare, and leave the rest to their own sweet selves.

I forgot to include in my list of "points" a careful examination every autumn in case any of the corms have became stranded on the surface; these should be gently pressed down and covered with the leaf-mould mixture, and a light sprinkling of this should also be scattered lovingly over the whole bed.

S. G. Reid.

THE CAPE PRIMROSES.

These beautiful Cape Primroses or streptocarpuses form one of the most useful subjects for greenhouse decoration during the summer months. Since their introduction great improvements have been made by crossing the various species and by selection. There are now numerous shades of colour, including blue, lilac, pink, and white. A white form, with a primrose throat is especially lovely, and is very effective arranged in glasses with Dendrobium phalænopsis. The fine variety Royal Purple and forms raised from it are among the best in cultivation, and they are chiefly remarkable for the size of their flowers. The Achimeniflorus group is very pretty and very free flowering.

Although perennials the best results are obtained with streptocarpuses by treating them as biennials; therefore, a stock should be raised annually from seeds sown at the present time. Use well-drained 32-size pots for seed sowing, fill them with a fine sandy compost, give a good watering through a fine-rosed can, and allow the pots to stand for a few hours before sowing the seeds. After the seeds are sown sift a sprinkling of the compost over them, then place the pots in a temperature of 65 deg. with a sheet of glass over them to check evaporation. When the seedlings are large enough to handle prick them off into pans, using a light, peaty soil, and when they become established, remove them to a temperature of 60 deg., and pot separately, using large 60's. At all times they must be shaded from the direct rays of the sun.

By this means good plants will be obtained by August, and these will flower continuously throughout the autumn. Partially dry them off, and allow a rest of several weeks' duration in the winter. The following February the plants should be put into 48-sized pots, which will be large enough for their future requirements; at this potting place a few half-inch bones over the drainage. A compost that suits them well consists of two parts good fibrous loam and one part leaf-soil, with the addition of a little fine charcoal and silver sand. Grow in a temperature of 55 deg. or 60 deg. and maintain a moist atmosphere by damping between the pots. Such plants will commence to flower in May, and furnish a succession of bloom throughout the summer.

If seeds are not required, pick off the pods, as this will assist the plants to continue flowering, besides improving their appearance. Supply with soot water and liquid manure at intervals to the growing plants. It is necessary to fumigate the house occasionally with nicotine compound to keep down greenfly, which soon obtains a hold on the foliage if not kept in check. If mealy bug appears, as it sometimes does on the under side of the leaves, methylated spirit applied with a camel hair brush will eradicate it. Streptocarpuses also succeed planted on indoor rockeries, for which purpose young plants from large 60's should be put out in February or March. Associated with ferns on a conservatory rockery they are both pleasing and effective.

J. Gardner.

A LARGE-FLOWERED HYBRID STREPTOCARPUS.

FLOWERS IN MASSES.

The excellent illustrations on p. 126 and 127 of Iris Beds at Kew prompts me to say how much more handsome and gorgeous are flowers when in masses of one sort than when a few clumps are set out in a border, for example. In a mass we get colour that harmonises with the immediate surroundings, when the planting is carried out with due regard to future effect. A few instances that occur to my mind while I write will serve to emphasise what I mean. For instance, how gorgeous are the beds of scarlet pelargoniums in front of Buckingham Palace each year; it is but a simple scheme, but what a glow of colour is produced! Take, again, the huge beds of shrubs and trees, both flowering and foliage subjects, as seen at Aldenham yearly; spiræas in variety, Forsythia suspensa, the Pearl Bush (Exochorda grandiflora), Hydrangea paniculata grandiflora, brambles, and so forth, all producing masses of decided colours, which create a marked effect in the landscape. Then there are the dogwoods in winter, golden elder, and purple hazel in summer, all attractive.

I need hardly point out, however, that these masses have their drawbacks, the most important being a want of attractiveness when out of season. In large or public gardens this is not noticed to the same extent as it would be in a smaller area. Where a large site is occupied by herbaceous plants a good opportunity exists for creating a rich effect by planting in masses. The double-flowered lychnis is most effective when seen occupying a patch six feet in diameter; Phlox Coquelicot, with at least a dozen plants in a group, rather close together, produces a blaze of colour that cannot fail to be appreciated. No subject shows the advantage of the massing principle better than the Dropmore variety of Anchusa italica, when the plants reach six feet high, as they will do if given good culture. The various heleniums, dwarf and tall, as well as the rudbeckias, all lend themselves to this system of massing.

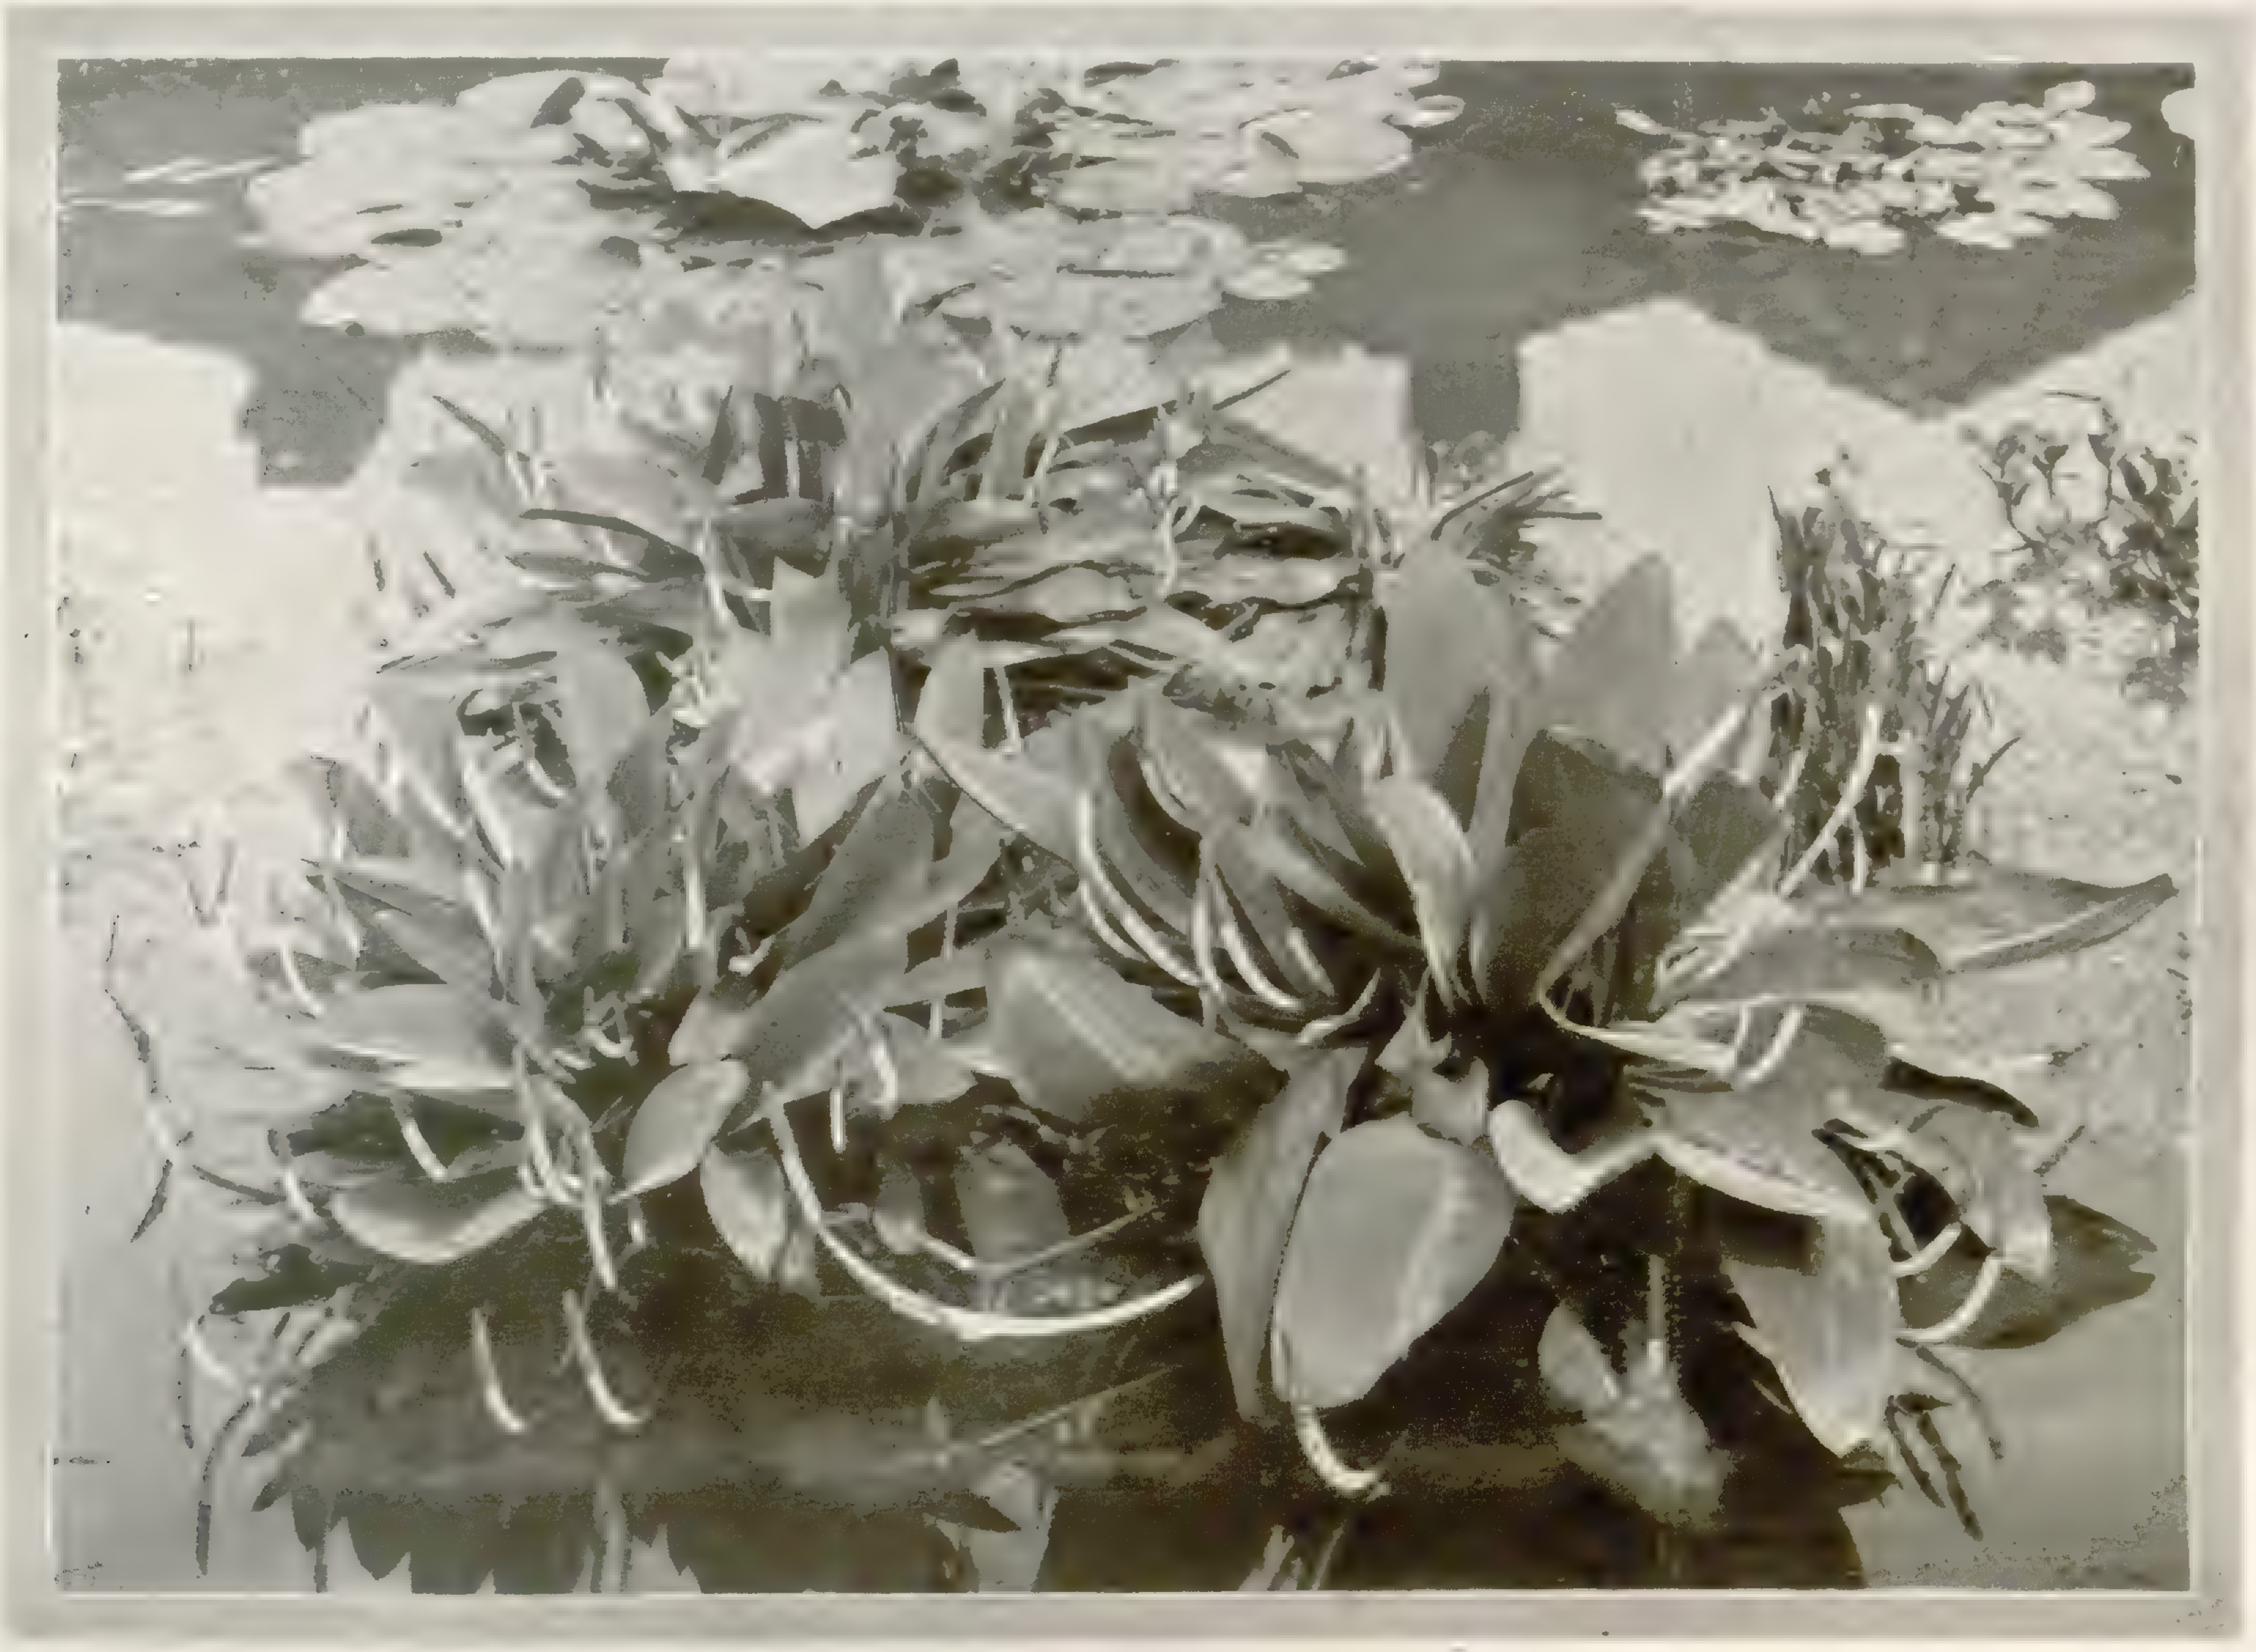
E. Molyneux.

Ardisia crenulata.—This pretty berry-bearing warm house shrub is known by two other specific names—crenata and crispa. It is an old plant in gardens, and forms an upright little shrub, clothed with dark green leaves of a particularly firm texture. The flowers are freely borne on the upper part of the plant, and succeeded by berries that when ripe are of a bright coral-red colour. They remain fresh and bright for months. It forms a very ornamental feature in the warm greenhouse or stove, especially during the winter months. There is a variety with white berries, but it is less effective than the type. Several other species of ardisia are in cultivation, one of them —Ardisia japonica—being almost hardy. This has also bright red berries, but they are not borne as freely as those of A. crenulata.—W. T.

ORONTIUM AQUATICUM OR "GOLDEN CLUB."

Few aquatic plants have such a charming and distinctive appearance as the subject of the accompanying illustration. Yet it is comparatively rare in gardens, although of very easy culture, requiring a square yard or so in an open tank or pond. The plant belongs to the arum lily family (Aroidæ), but is often devoid of the spathe or large bract which is characteristic of that family. The spathe, if present at all, is small, and placed some distance below the spadix. The inflorescences are produced freely on quite small plants in late May and June, and present a remarkable appearance in the distinct combination of the pure white peduncle surmounted by the golden-yellow spadix. The foliage is handsome, and a welcome change to that of nymphæas and other popular water-loving plants. In common with the bulk of aquatics, the plant delights in a rich, greasy loam, to which is added about one-third of its bulk of cow manure, and it thrives best if planted with its crown from nine inches to a foot below the water level, as in this way the stalks of the flowers are sufficiently short and stout to hold the spadix well above the water. It is a native of North America, where it is found in ponds from Massachusetts to Pennsylvania, and is quite hardy in this country.

C. P. Raffill.



A BEAUTIFUL WATER PLANT (ORONTIUM AQUATICUM). [Photo: C. P. Raffill.

Early Pea, The Pilot.—Among so many varieties of culinary peas it is difficult to grow and test all, and also not easy to select some few without any previous experience. I can recommend The Pilot as quite an excellent early pea. In growth it reaches from 3ft. to 4ft. in height, with stout haulm, and bears an abundance of large pods of excellent peas, and in a very short space of time too. I do not know by whom this variety was raised.—E. M

MAINTAINING THE BALANCE

I notice that Mr. J. Whittle, writing on the care of young fruit trees (page 154) observes that "all fruit trees should be pruned the first year of planting, not only to balance the check received at the roots, but also to lay a good foundation." I am not drawing attention to the above remark out of any spirit of hostile criticism, but rather because it seems to be a matter which requires a bit more sifting. Everybody is agreed, of course, as to the desirability of pruning young fruit trees for the purpose, as your correspondent rightly points out, of laying a good foundation, and I fully agree with him that in many cases vigorous established trees are annually overpruned. The point, however, on which I think it is desirable that more light should be shed is that of maintaining the balance; what it really means, and whether there is any necessity for it. There are many expert writers on fruit culture who, like your correspondent, recommend pruning newly-planted fruit trees the first year, and they mostly use as an argument in favour of their methods the desirability, as Mr. Whittle puts it, of balancing the check received at the roots. Just so, but we must remember that there are many fruit growers whose practical ability and experience are above question who advocate the pruning of young trees, not immediately following the planting, but a year later. I make no pretence here of saying, from my own point of view, which is right and which is wrong, but while first-year pruners lay such stress on the importance of maintaining the balance between root and branch, second-year pruners discard the point altogether, apparently not caring a fig whether the balance is maintained or not, and, in face of this, I, like Rosa Dartle, "merely ask" if this maintenance of balance is necessary. Why should the balance be maintained, and what is likely to happen if it is not maintained? These are the questions, and the opinions of some of the readers of the Gardeners' Magazine on the point would not only be interesting, but useful.

I take it that everybody is agreed as to the desirability of pruning young trees, and the object of it is to get growth. Very well then; do we get better growth, and, consequently, a better tree, when we prune the first year, and balance the check received at the roots, than if we leave that tree a year in the ground before pruning it, and never consider the question of balance at all? If the verdict is given in favour of the latter then this concern about balance becomes so much moonshine, and we can well afford to drop it out of fruit-growing literature altogether.

It may be taken for granted that the word of a man who is depending for his living on commercial fruit growing is worth considering in a matter of this kind, and a short time ago I was talking to a market grower on the subject of first and second-year pruning. "What I want," said he, "from my young trees in the first place is growth. I prune for that purpose. I have tried first-year pruning and I have tried second-year pruning, and I get better growth as well as a smaller percentage of stunted trees by the latter method than the first, and these are the reasons why I now adopt it with all the trees I plant." I murmured something about losing time, but the grower wouldn't have it, and contended that any of that valuable commodity which may appear lost in the first place is quickly made up, and, in the majority of cases, the tree that is left intact for a season before being pruned is the best at the end of a period of a few years. Then I played the trump card from the pack of the first-year pruner, "But what about maintaining the balance?" I got no further, for the answer came, "Bother the balance: what I want from my young trees is growth, and I am more likely to get it from a tree that has been in the ground a year, and has got hold at the root, than I am from one that has just been transferred from a nursery, and in the lifting has been subjected to root pruning, the natural result of which is to check growth."

This is the case of a man who is growing fruit, not for pleasure or amusement, but for profit, and he may be depended on to follow the method which, in his judgment, gives the best results. There, gentleman, as the lawyers say, I place the case before you without bias. No first-year pruner can say that a second-year pruner is wrong if the latter gets good results, any more than the latter can justly condemn the methods of the former if they are successful, and the point is, which is the best? Naturally, each partisan will incline to his own view, but what I should like to see made more clear is the rights and wrongs of that oft-repeated phrase, "Maintaining the balance." G. H. H.

THE NATIONAL HARDY PLANT SOCIETY.

As was to be expected, this newly-formed society has been the subject of much comment, and not a little criticism, for, whilst from the very outset a large number of the leading hardy plant specialists have expressed their entire sympathy with the aims and objects of the society, and immediately associated themselves with the movement, there have been some who show signs of misgiving, if not actual disapproval, at this admittedly bold undertaking. It is, however, mainly, if not entirely, on the ground that the multiplication of horticultural societies should not be hastily encouraged that criticism has arisen, and with this view we ourselves are ready to agree. It is, indeed, in the hope that by the formation of one strong society to look after the interests of all classes of hardy herbaceous and kindred plants there will be no need to multiply the number of small societies for separate subjects that the promoters have set themselves to the task. Quite recently proposals have been made to form specialist societies for pansies and violas, for pæonies, and for phloxes, and surely all will agree that it is far more desirable that all lovers of these, and any other hardy-flowering plants, should unite to form one powerful society that shall be able to do really good work on behalf of pansies and delphiniums, phloxes and pyrethrums, alpine and rock plants, as well as the denizens of the herbaceous border. That the field is wide we are fully conscious, and the only reply we can make to the question that has already been often asked as to where we shall define the limits of our sphere of labour is that the extent of our operations will, and must be governed by the amount of support forthcoming. All who have at any time participated in the work involved in getting a new society afloat will realise something of the amount of work that has had to be done before the National Hardy Plant Society could commence real business, but it is gratifying to be able to say that we have been able to arrange, even for the first season, to co-operate with several horticultural societies, and to undertake to render assistance at their summer shows.

Next year we hope to do much more in this direction, and we also intend to collect and disseminate information on all matters relating to hardy plant culture. The society is fortunate in having upon its council and committees many of the foremost cultivators, and eminent scientists, and it is with the utmost confidence that the National Hardy Plant Society will achieve great things, and prove itself in every sense worthy. We hope to receive the support of every lover of hardy plants.

A. J. Macself, Chairman of Council.

AMONG THE ALPINE FLOWERS.

"Oh, who can speak of the joys of spring's young morn,
When wood and pasture open on his view,
When tender green buds blush upon the thorn,
And the first primrose dips its leaves in dew?"
—Clare.

Happy are the poets who can thus idealise the days of spring, which, unfortunately, are not always so halcyon as they would lead us to believe. Those of us who find their delights among their flowers cannot always join so joyously in the acclamation of the bard of these early days of the year. "Early" seems a false term, indeed, now that March has run its course, and when a fourth of the year is gone. But March is early in the garden year, and we can thus look forward to a happy escape from the cold winds and bitter nights which have marked its course this season, and which have retarded some of our favourites and have driven others to an untimely end. Yet we have much to enjoy, though, as we sally into the garden to work among or to enjoy our flowers, we feel the cold winds biting, or observe some bright flower seared as by fire. Yet it is more profitable, as well as more pleasant, now to look at the brighter side, and refresh ourselves with the beauty of the flowers which are in blow.

Hepaticas.

The name of hepatica lingers long, and lovers of our olden names will not readily merge this title in that of anemone, which conveys to the mind a tale of a different class or classes of flowers. We have almost lost the use of the old title of "Noble Liverwort," but methinks that of hepatica will long survive, both for the varieties of Hepatica triloba and acutiloba, and for the great Hepatica, or Anemone, angulosa. Thus we retain it, and love to speak of our flowers by its familiar sound. They are happy who have big groups of some of these, and we have in our mind's eye a broad border in a Sussex garden where there are hundreds of flowers of the lovely single blue form of the common H. triloba, as well as many visions of the others in numberless gardens seen by us when these hepaticas were in bloom. The double red one, ofttimes called the double "peach"-coloured, is a great beauty, and is hard to surpass; while its sister flowers, the double blue and the double white, are both scarce nowadays, the latter, although re-introduced and offered by the trade, being yet scarce, and not giving promise of a long or happy career in our gardens under the conditions in which the double red variety thrives so well. As for the angulosa varieties, they are indispensable with their larger leaves and great flowers, most of which are very beautiful. In very truth, all these hepaticas are lovely flowers, and they are happy who have spreading carpets of them. With the writer they always do best on the cold side of the rock garden and on flat spots on the slopes facing the north and north-west, where they receive but little sun, and where, almost undisturbed, they are steadily growing finer every year. These angulosa varieties in blue, pink, rose, and white, are lovely flowers.

Saxifraga Cherrytrees.

The different saxifrages which had their origin in the garden of the late Mr. Boyd, of Cherrytrees, such as Boydi, Faldonside, and Cherrytrees, have all a certain reputation for delicacy in our gardens—a reputation not unjustly given, inasmuch as they sometimes die off and their owner is left to mourn their departure. Of the trio that called Boydi, one of the finest of all the yellow saxifrages of its class, is the best in colour, and, at the same time the most troublesome to grow. The others are less bright, but are easier to cultivate, yet all will do fairly well if on a raised terrace of sandy soil, and with plenty of grit about them, a top-dressing of fine soil being annually worked in about their tufts. Cherrytrees is a very pretty one, after the fashion of Boydi, but considerably paler in colour.

Scilla bifolia rubra.

A few of us are fortunate enough to own a few bulbs of the old red variety of Scilla bifolia named rubra, which is too scarce to be offered by the bulb dealer, and is hardly ever to be met with. Too frequently the unwary are led into securing the pretty flesh-coloured S. bifolia carnea, which is very pretty, no doubt, but which is far from being so bright and attractive as the true rubra, which is of deep pink or red. A little clump (I cannot call it more) in the rock garden has been, and still is, very beautiful, sheltered from the cold winds by a dark-coloured stone, and holding up its flowers bravely to our admiring glances. There are also here several of Mr. James Allen's pink varieties, but, after all, he would hardly claim that they are finer than this old form, although differing not only in shade but also in period of flowering.

Corydalis tuberosa alba.

A somewhat tantalising search for the correct name of a pretty corydalis, or fumitory, results in discovering that a plant which I have had for a while under several names must bear that given above. Although suitable for the border also, it seems best adapted for the rock garden, where, a little above breast high, it looks much prettier than when on the ground level. It likes, however, a fairly moist soil, so that some consideration is necessary to secure this at the height mentioned. This is one of the prettiest of the older of the hardy corydalises, and with its prettily formed leaves and its clusters of white flowers it forms a rather pleasing feature of the rock garden. My first flowers opened early in March this season, but the cold weather has retarded others, which are only appearing through the soil as this is written. It is thoroughly hardy, and is much prettier than the typical C. tuberosa. It appears to have been known as C. albiflora, in addition to other names.

Other Flowers.

There are also early heaths, in white and purple, and almost pink; there are violas not a few, primroses and polyanthuses in plenty, together with their allies the oxlips and cowslips to bear them company. Then we have little hardy cyclamens, snugly sheltered from the cold winds, a soldanella or two, chionodoxas in several species and in different varieties, scillas, such as S. bifolia and its varieties, with S. sibirica; some late snowdrops, not yet superfluous; a cardamine or two, the dwarf form of Gagea lutea, several early saxifrages, daphnes, daffodils in plenty, including the little cyclamineus, and a variety of other species, besides the big trumpets now so fine, with some chionoscillas, Synthyris reniformis, and various others, which, despite the chill winds, struggle to maintain their beauty. All round we see promise of many other plants which await the more genial weather yet to come, when the rock garden will be brighter still and more joy-giving to all who love the alpine flowers. S. Arnott.

VARIEGATED DOGWOODS.

The inclusion of really good variegated-leaved shrubs in the garden is frequently attended with very happy results, especially when a distinct feature is made of them in one particular place, such as a large mass of varied subjects with different coloured foliage nicely blended, or when beds or groups are given over to one special kind of shrub with silver or gold variegated leaves. The casual dotting about of such shrubs cannot, however, be recommended, for instead of bold colour effects being produced the result is of a weak spotty character. Some discrimination must needs be shown in selecting variegated-leaved shrubs, for although some are very beautiful and keep their colour well throughout the year, others are not worth growing, the colour at the best of times being indifferent, whilst the first week of bright sun spoils the leaves.

In the genus Cornus both kinds may be found, for several variegated-leaved varieties are included amongst the most useful shrubs of this particular character, whilst others are quite worthless. They have the advantage of being easily grown, whilst several are doubly valuable on account of their bright red stems, which are very effective in winter. In the following descriptions the more worthy ones are indicated.

Cornus alba var. sibirica variegata.—This is a silver-variegated variety of the Northern Asiatic species, C. alba, which is so frequently grown for the sake of its red bark for winter effect. The variety forms a dense bush, three to five feet high, with large leaves, green in the centre, with wide irregular margin of silver. It keeps its colour well, and is easily the best silver variety of this species.

C. a. var. Spaethi.—Of golden variegated shrubs this certainly occupies a foremost position, for it is one of the most useful and beautiful foliage shrubs grown. The leaves are similar in size to those of the type, and they are richly variegated with gold, green, and grey. Much of the golden colouring is about the margins, but it passes to the centre of the leaves, and mingles with the green and grey in broad irregularly-shaped bands. From the time the leaves appear until they fall the colour keeps good, and has not been known to burn during the hottest summers. As a rule, both this variety and the first-named may be increased by means of naturally-layered branches, which root readily where they come in contact with the ground.

C. a. var Froebeli.—This also is a golden variegated variety, but the colour is dull in comparison to the last-named, and it is hardly necessary to include it in collections where the former plant appears.

C. a. var. Gouchaulti bears some resemblance to the last-named. It also is golden variegated, but inferior for general work to Spaethi.

C. a. var. variegata has silver variegated leaves. It is showy, but inferior in merit to the silver-leaved kind previously mentioned.

C. brachypoda variegata.—A doubt exists as to the correct nomenclature of this plant, though it is under this name that it is met with occasionally in gardens. At its best, its silver variegated leaves make it a conspicuous object, but unfortunately it is delicate, and cannot be recommended for general planting.

C. candidissima variegata is a silver variegated form of this North American species. The variegation is not very good, and the plant is not recommended for general planting.

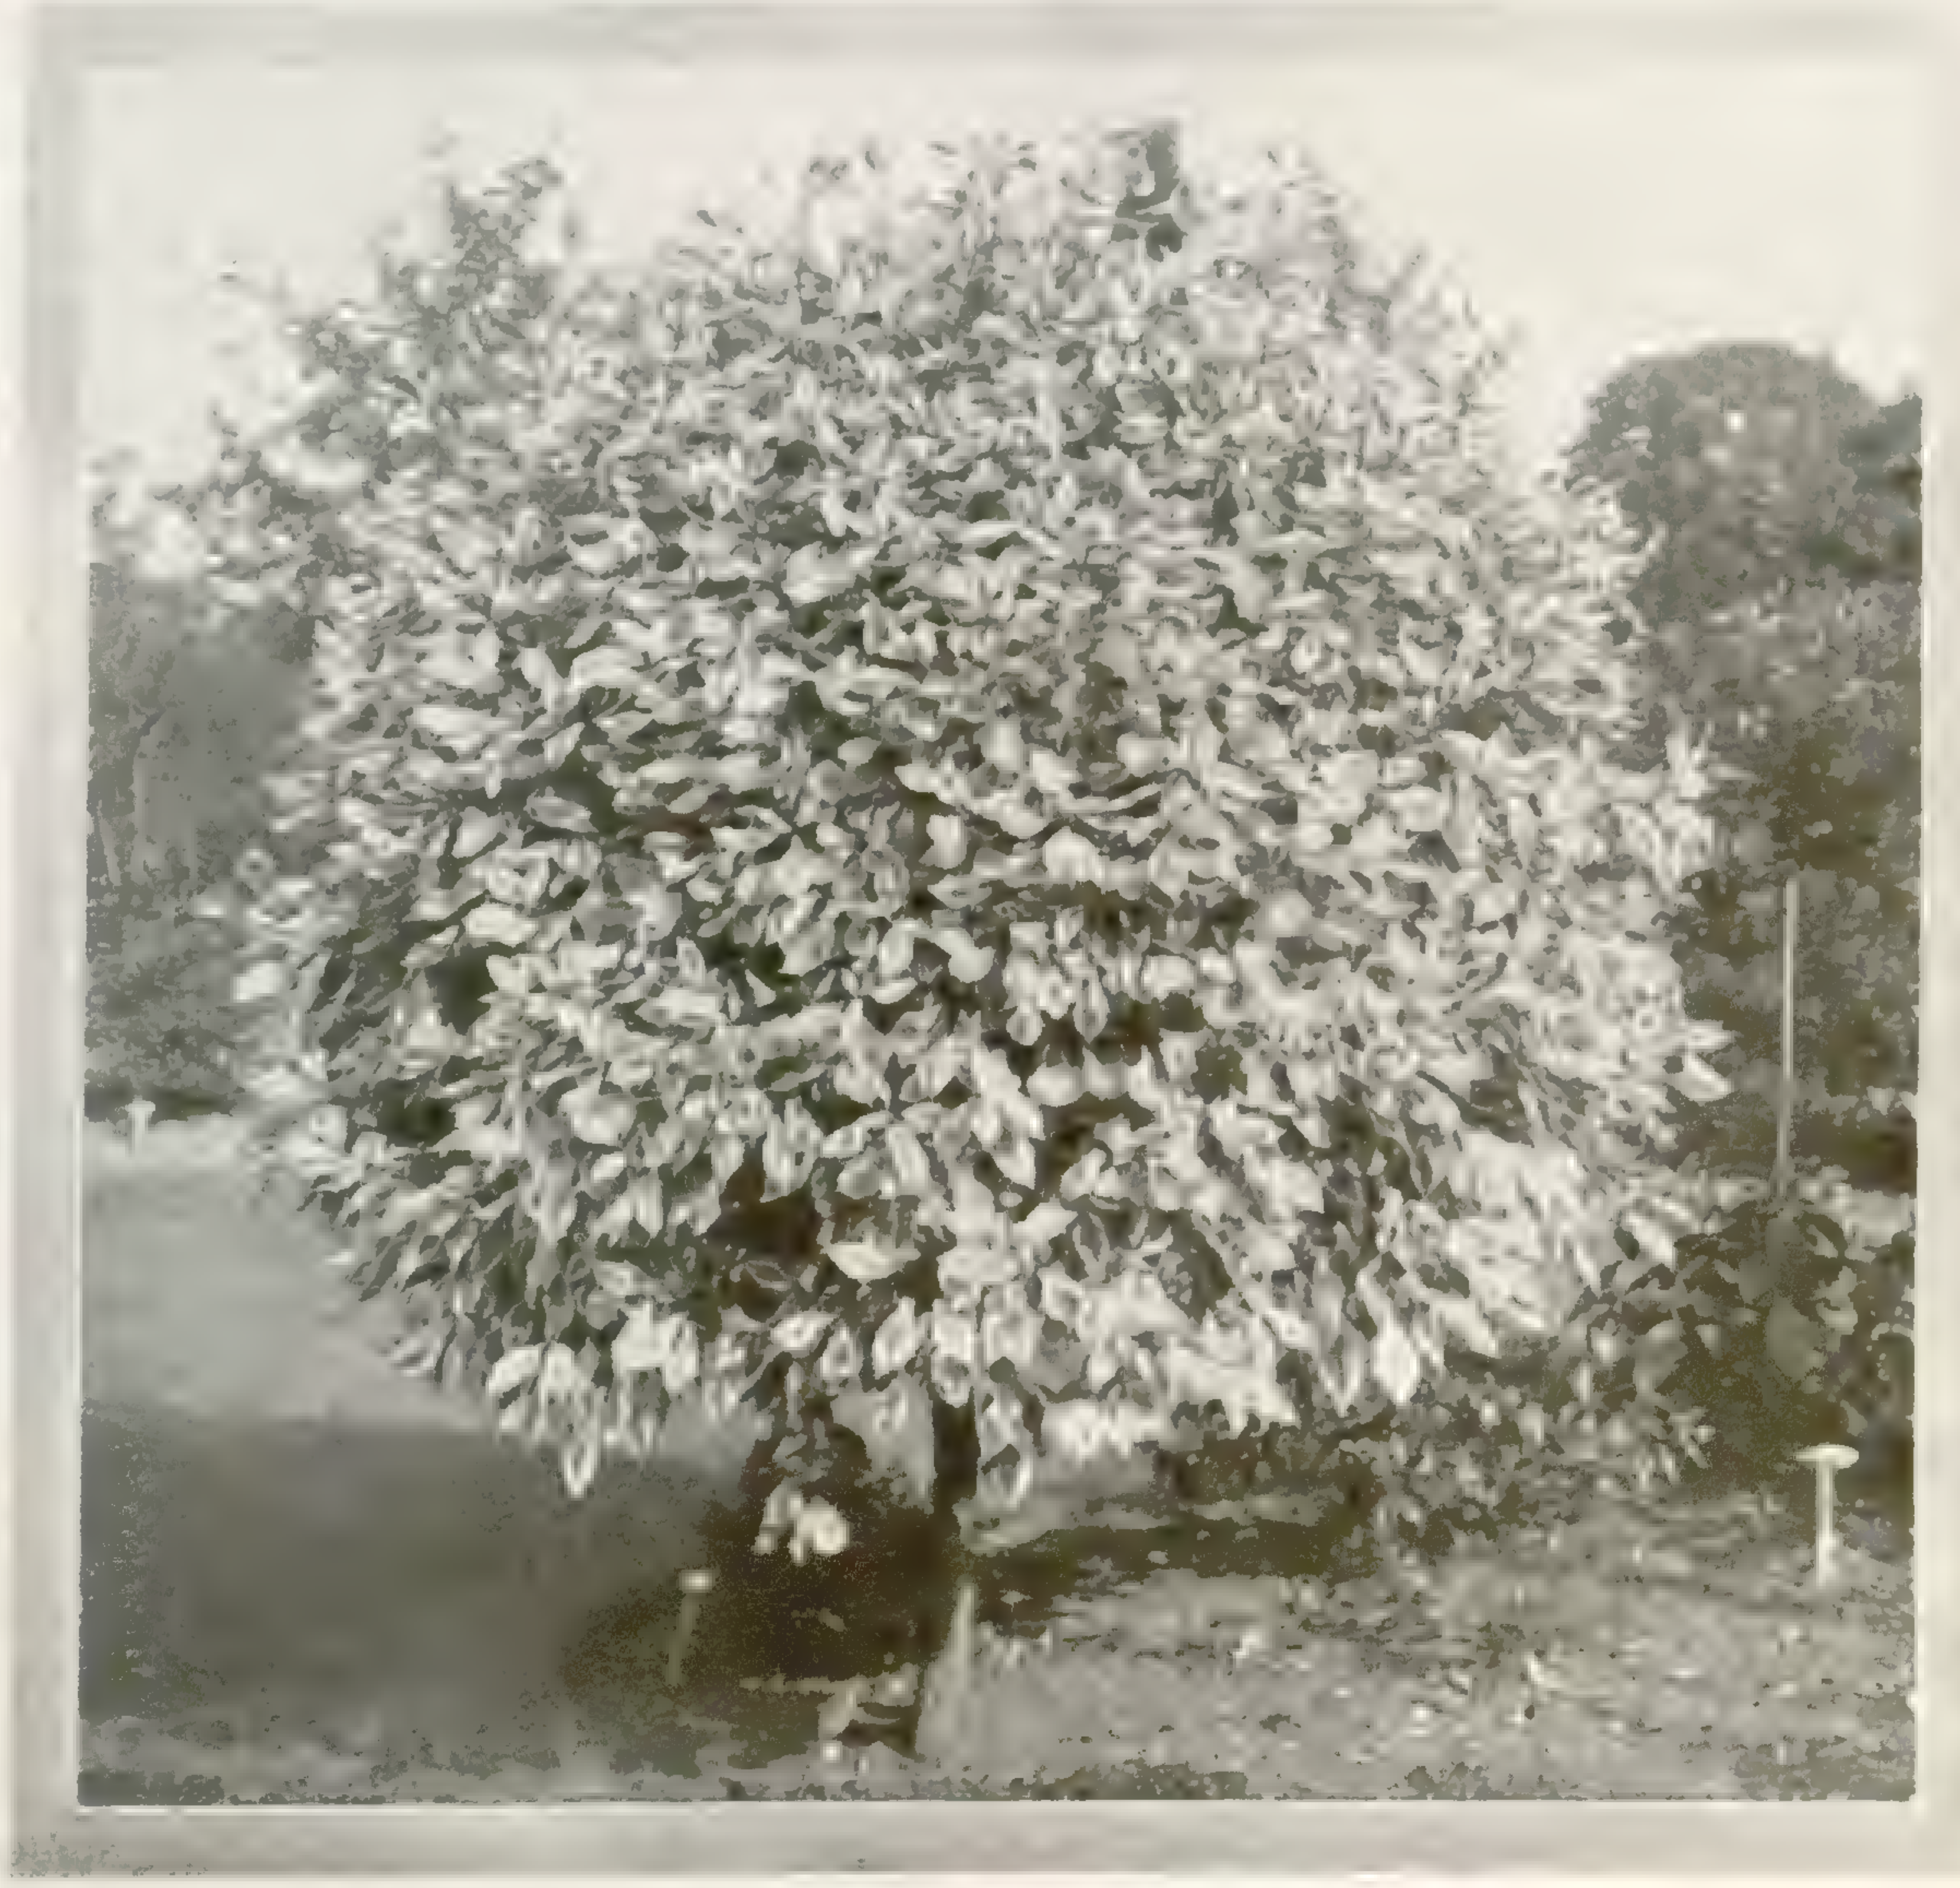
C. Mas, the common Cornelian Cherry, produces a couple of variegated varieties of decidedly ornamental appearance. They are often grafted as standards or half-standards on stocks of the type, and are excellent subjects to use in groups of coloured-leaved shrubs.

C. Mas var. elegantissima forms a head of slender branches, which bear leaves somewhat smaller than those of the type, variegated with gold. In some instances the gold occupies the greater portion of the surface of the leaf, whilst in other cases it may be intermingled with green patches or form an irregular margin round a green centre. It is not so hardy as the type, and ought not to be planted in places subject to late spring frosts.

C. Mas var. variegata is as strong growing as the type. It is of sturdy, upright habit, and bears leaves beautifully margined with silver. Grafted on tall stems, it assumes the habit of a dwarf tree.

C. sanguinea var. variegata is a poor variety of the red osier dogwood. It is of weak habit, and the colour is weak and ill-defined; in fact, it may be described as a representative of the worst form of variegated-leaved shrub.

For use as specimen beds the two best varieties are C. alba sibirica variegata, silver; and C. a. Spaethi, gold. W. D.



A FINE SPECIMEN OF CORNUS ALBA SIBIRICA VARIEGATA AT ALDENHAM HOUSE.

A handsome Dogwood with silvery-white variegation.

Blinds.—The shading of plant stoves is always an important item, and frequently an expensive one. Most readers will agree that lath blinds are by far the best for all purposes, only that they are also the most expensive. The Japanese split bamboo sun blinds are excellent substitutes, and may be fixed at less than half the cost. The vendors supply these blinds with all the necessary fittings, which can be put into position without skilled labour; all these blinds shade the glass exceedingly well, and allow ample light to pass. All blinds may now be fixed into position ready for sudden outbursts of sunshine.—JOHN DONOGHUE.

HARDY FRUIT CROPS.

During the past three years I have closely watched the progress of the trees in several orchards. The soil in one orchard is rather shallow, but of fairly good quality, and the subsoil is a gravelly one. In the other orchards the soil is a rich loam, and very deep, with a sandy subsoil.

In the orchard first referred to the trees have, during the past two or three years, made moderate growth of medium strength, and the flower buds have been plentiful; crops satisfactory. In the other orchard the trees have made much wood of great strength and very few flower buds, many of the latter being on the tips of some branches three feet long in the case of standards. Root pruning has done some good, but still the trees are making too much wood.

In the orchard where the soil is shallow on a gravelly subsoil it has been possible to top-dress and feed with satisfactory results. Of course, we have experienced two summers unfavourable to the ripening of the wood of trees that have been planted in a deep, rich soil. Both pear and apple trees are, this spring, bearing a grand lot of flower buds on the spurs, and well-matured branches, and I notice that those specimens in the hottest position in the gardens are looking the most promising. These trees are all growing in a rather shallow soil.

Gooseberries and currants look very promising, as also do cherries.

GEO. GARNER.

GREENHOUSE MANAGEMENT.—THE AMATEUR'S GREENHOUSE, the popular book by T. W. Sanders, not only treats of the selection and cultivation of greenhouse plants and flowers, but gives full instructions how to build a greenhouse and how to heat it, as well as every detail as to the management of the plants and flowers grown in it. The price of this book of 416 pages is 5s. net, or by post 5s. 6d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

PHALÆNOPSIS.—The species, natural hybrids, and garden-raised hybrids will now be showing signs of renewed vitality, and any repotting necessary should be attended to without delay. It is not advisable to disturb the roots more than is absolutely necessary. Where they have become attached to the sides of the receptacles in which they have been growing, the old potting compost, and as much of the drainage as may be desirable, should be carefully picked out and replaced with clean drainage and chopped sphagnum moss. If the plants have outgrown their receptacles, and require more room, the old potting compost and as much of the drainage as possible should be removed, so that the roots may be seen. I have always found that the roots of most orchids may be detached readily when they are in a wet state, and where phalænopsis occupy baskets it is well to immerse the basket, or that portion to which the roots are adhering, in a pail of water, permitting it to remain for a few minutes. Then, by inserting the edge of a thin knife under the roots, with a little care they may be gradually detached. These plants require a copious supply of water at all seasons of the year, and it is essential that ample drainage be provided. This may consist of broken crocks and charcoal. The potting compost I have always found most suitable for phalænopsis consists entirely of clean chopped sphagnum moss intermixed with some silver sand or broken charcoal. This must be pressed moderately firm among the roots. Carefully shade from strong light for a few weeks after repotting, and maintain an even temperature of from 70 to 75 degrees, with plenty of humidity in the atmosphere by frequent damping and spraying the floors, staging, etc.

ANÆCTOCHILUS, and the allied genera, macodes, goodyera, hæmaria, etc., belong to the small section of orchids whose value rests in their beautiful foliage. This section of orchids are not so extensively cultivated as they used to be, or as their merits deserve. At the time when extensive collections of vandas and ærides were cultivated they were often found growing luxuriantly on the surface of the potting compost of the large specimens, but one seldom sees the plants now, unless they are accommodated in propagating pits, or under large bell-glasses. The several species are best propagated from divisions made at the potting season. They are best accommodated in pots or shallow pans provided with ample drainage. The potting compost must be of a very light and open nature, chopped sphagnum moss intermixed with fibrous peat, some broken leaves, finely broken crocks, and silver sand. Make the compost moderately firm. Supply with tepid water as soon as potting is completed. Keep the plants close and well shaded until they have established themselves in the fresh material. The atmosphere about the plants must be practically of a saturated nature at all seasons of the year.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

IXORAS.—These useful decorative flowering plants may be grown for autumn by rooting cuttings singly in thumb pots, and shifting them into other pots four or five inches in diameter. They should be grown on steadily near the glass in a light position where a moist atmosphere and a brisk stove temperature are maintained. Some of the varieties will need the extreme tips removed to induce them to form neat bushes. During the hottest part of the day they may be given a light shade during bright weather, especially immediately after repotting. When the pots are well filled with roots and the growth is vigorous, alternate supplies of clear soot water and weakly diluted farmyard liquid manure will be found beneficial. An occasional syringing with insecticide will be advisable, as a preventive of insect attacks. The syringe may be used twice daily, and as the flower buds begin to develop slightly less moisture will be necessary.

CALADIUMS.—The tubers which were started early in the year are now growing freely and must be given more root room, otherwise their progress will be retarded by the production of spathes instead of leaves. Those required for house or table decoration, and the dwarf or edging varieties, such as C. argyrites or C. minus erubescens, will need to be retained in small pots; the large 60-sized, or four-inch pots are ample for these varieties. Plants to be grown into large specimens for remaining in the stove should be allowed ample rooting space, as the caladium is a gross feeder, the quality of its ornamental foliage being much increased with liberal treatment. For this potting, which in many varieties will be the final, a slightly richer compost may be used by adding some manure from an old mushroom bed, or sheep dung, which has been dried and rubbed fine.

CYPERUS ALTERNIFOLIUS. — The foliage of the cyperus is most serviceable for decorative purposes, and very effective when tastefully associated with cut blooms arranged in vases, it being of exceptional value also for use as a green decorative plant for dark positions in the mansion, thereby saving better foliage plants, such as palms, ferns, etc. It will thrive extremely well in almost any position where an intermediate temperature can be maintained. The variegated form is very handsome when grown well, but unfortunately it is subject to loosing its beautiful variegation, and reverting to the green type. In preparing a compost for the variegated form use equal proportions of silver sand, powdered charcoal, and peat.

STREPTOCARPUS HYBRIDS. — These are extremely valuable, and are much more serviceable for cut bloom than gloxinias, which flowers they closely resemble, but I am certain their profusion in blooming, and the variation in the shades of colour are almost unsurpassed by any other part in cultivation. My experience with streptocarpus is they are best treated almost as annuals, that is, for spring and summer flowering sow the seed about June and July, and for autumn and winter seed may be sown now.

PALMS are almost indispensable for indoor decorative purposes, and need attention to repotting occasionally. I do not advocate repotting of palms until they really are in need of larger pots; systematic feeding at the roots will keep them in a healthy robust condition for two or three years, or even longer under favourable circumstances.—John Donoghue, Bardon Hill Gardens.

THE FLOWER GARDEN.

SWEET PEAS.—providing everything is in readiness, planting may be proceeded with. There is much diversity of opinion with regard to sweet pea culture, but for anyone requiring abundance of good blooms the following method of planting will be found to answer. Assuming the ground has been thoroughly prepared, and well enriched with manure, the plants should be put out from eighteen inches to two feet apart, according to the strength of the variety, and allowed to grow naturally. If grown in clumps then from three to four plants will be ample. When planting is completed short twiggy sticks about eighteen inches high should be placed around the plants, to protect them from the winds, and nurse them along until the permanent supports are given. A strict watch must be maintained for any pests that are likely to injure the growths. Seeds may still be sown in the open ground for providing a late crop of flowers.

ROSES.—The pruning of teas and hybrid teas may be accomplished now with safety. The same advice applies to these as that which was given earlier for hybrid perpetuals. The China, Bourbon, and Provence types will not require such hard pruning; all that is necessary is the thinning out of the weak growths from the centres of the plants, and slightly shortening the strong ones.

ANNUALS, HARDY.—A further sowing may now be made, providing the ground is in good working condition. To maintain a supply of Gypsophila elegans for decorative purposes it is necessary to make several sowings at intervals of three weeks.

POLYANTHUSES.—The improved strains are a welcome addition to our spring gardens and woodlands, and success rests in a great measure on early sowing and careful cultivation during the young stages of growth. Like the majority of the primula family the polyanthuses favour a cool shady position, where the hot sun cannot reach them, especially in the seedling stage. To obtain plants for flowering next spring, it is necessary to sow the seeds now in boxes, placing them in a cold frame, keeping them shaded until germination takes place, after which a little light may be afforded, but still shading from the sun. When the seedlings are large enough to handle they should be transplanted into boxes and allowed to remain in the frames. When they have well filled these they may be planted out in a cool nursery border. This should be enriched with decayed cow manure. —E. C. Pooley, Gnaton Gardens.

FRUITS UNDER GLASS.

EARLY PEACHES AND NECTARINES. —The shoots of these will now require to be tied in regularly, both for neatness and general training, for next season, and also to admit light to the fruits. Before commencing the tying however, remove all the shoots that are not required for next season, or for the well-balancing of the trees. If the trees are young, and have not filled the trellis, train the shoots regularly over as much space as possible, but on no account tie in more than are required. Water thoroughly whenever required, using water at a slightly higher temperature than the normal temperature of the house. If the border is well watered just before stoning commences this should, as a general rule, carry the trees over that period. A good mulching of spent manure from the mushroom bed will keep the roots moist and near the surface.

SUCCESSIONAL PEACH HOUSES.—Trees in these may be now disbudded, as in the same manner as recommended some time since for those in the early houses. Fumigate with nicotine for aphis, which sometimes attack the tips of the young growths when watering, syringing, and airing are not properly attended to.

EARLY VINERY.—Commence thinning the bunches as soon as possible after the berries are formed. Cut away any bunches that are not required, it being better to finish 100 bunches well than double the number indifferently, and in thinning avoid letting the berries come in contact with the hand, unless it is the berry that is held for thinning purposes. To the inexperienced a little crooked twig will be useful for holding the bunch when thinning, or a small piece of matting. An experienced operator will find it best to hold one of the bottom berries, and then cut it away when the thinning of the bunch is finished. In the case of very large bunches that require support these should be looped up carefully with small twisted raffia. When the thinning has been completed give the border a good dressing of some approved fertiliser, and water thoroughly.

FIGS.—The earliest of these in pots will now be swelling freely, therefore make frequent applications of liquid manure, as it is at this stage that much nourishment is necessary. A good top-dressing of thoroughly decomposed cow dung or horse manure will be found of the utmost advantage. Keep the temperature at from 65 to 70 degrees in the day, and from 60 to 65 degrees at night.—W. A. Cook, Leonardslee Gardens.

EXHIBITIONS AND MEETINGS.

◆

United Horticultural Benefit and Provident Society.

We have pleasure in now publishing the report of the committee of this society for 1910, as promised on p. 214.

In presenting its report for the year 1910, together with the balance-sheet for the same period, the committee has much pleasure in recording steady progress in membership and in financial matters.

The committee takes this opportunity of referring to the lamented sudden decease of King Edward VII. At the committee meeting of May 9, it was resolved to convey to her Majesty Queen Alexandra, and to King George V. letters of condolence and sympathy from the United Horticultural Benefit and Provident Society, and to each of these letters the committee received a reply on behalf of their Majesties. The letters have been inserted as a permanent record in the society's minute book.

MEMBERSHIP.

The membership has steadily increased. Seventy new members were elected during the year. Among the deceased members were Mr. W. Bunce, who joined the society forty-two years ago, in 1868, and who had the sum of £72 19s. 7d. to his credit in the society's funds; and Mr. Alexander Clark, who joined in 1885, and left £44 14s. 11d. to his nominee. The total amount paid out to nominees of deceased members was £147 10s. 4d. It is of interest to record that a sum of thirty guineas was paid out to a member who had been lapsed for thirty years. Another lapsed member received the amount of 12s. 7d. due to him. The committee is of opinion that the payment of the sums standing to the credit of its lapsed members when they reach sixty years of age, reflects credit upon the conduct and constitution of the society.

The total amount of sick pay to benefit members during the year was £561 0s. 6d., as against £571 15s. the previous year. The amounts for each month may be set out thus: February, 1910, £75 4s.; March, 1910, £60 5s.; April, 1910, £35 9s.; May, 1910, £43 19s.; June, 1910, £41 16s. 6d.; July, 1910, £27 3s.; August, 1910, £29 17s.; September, 1910, £29 14s.; October, 1910, £34 19s.; November, 1910, £66 5s.; December, 1910, £54 19s.; and January, 1911, £61 10s.

Of the total amount of £561 0s. 6d., £110 was paid out to chronic sick members.

Statistics recording the age at which members joined the society, and the total numbers between certain stated ages, are published in the accompanying actuarial report; but for the sake of convenience the following computations have been extracted from that document. The present age-classification of members shows:—

289	between	ages	20—29
438	,,	,,	29—39
347	,,	,,	39—49
170	,,	,,	49—59
79	,,	,,	59—69
1	who is over the age 69		
1,324			

These figures are regarded as very satisfactory; they do not, however, include non-contributing members who are over seventy years of age.

The net number of benefit members is 1,366.

Only three members have transferred from the lower to the higher scale during the year.

Twenty members have taken advantage of Rule XVIII., par. 3, which enables those who have reached the age of sixty to withdraw "twice the amount credited to their account as interest in the previous year." By such withdrawals they are furnished with a ready means for the payment of their subscriptions, which is a great boon. One member withdrew £6 18s. 2d. under this rule, and, being over seventy, he, by virtue of Par. 4 of the same rule, withdrew £50 from his balance account. Another member over seventy withdrew £54 0s. 11d.

CONVALESCENT FUND.

Very few applications were made for assistance from this source. The subscriptions, including five guineas from N. N. Sherwood, Esq., V.M.H., amounted to £10 0s, 6d., and the payments to £8.

BENEVOLENT FUND.

Subscriptions to the benevolent fund amounted to £238 10s. 1d., and the payments therefrom to £90 16s.; the latter amount including the sums regularly paid to several members over seventy years of age, as well as a few grants made to members or members' widows, in great distress. A payment of £2 was granted to a necessitous member to assist him to pay a doctor's bill: and £3 was granted to a member's widow who was left in very straitened circumstances. In all cases the committee exercises its utmost discretion in making grants from this fund.

In considering the amounts paid out from either the Benefit or Benevolent Funds, the following facts are instructive:

1. From 1898 to October, 1910, inclusive, one member has received the total sum of £177 7s.
2. From 1904 to 1910, another member has received £98 12s.
3. From 1906 to 1910, a third member has received £73 2s.
4. From 1905 to 1910, another received £68 8s.
5. Three other members have had respectively £26 8s., £21 18s., and £20 9s. 6d.

Management Fund.

The strictest economy, consistent with the proper working of the society, has been observed in this department. The total management charges amounted to £222 9s. 7d., as against £195 11s. 10d. in 1909, and £192 19s. 10d. in 1908.

Acting upon a suggestion made by the society's auditors that a card indexing system be adopted to facilitate the secretarial work, a sub-committee was appointed, and after visiting Mr. Collins' office, to examine his books and method of procedure, and after inspecting some of the card-indexing outfits at the office-furniture establishments, it was unanimously decided that there would be no saving of labour, nor any gain whatever, by the adoption of the card-indexing system. The sub-committee was much impressed by the neat, orderly, methodical and detailed methods practised by the secretary, and recorded a hearty expression of appreciation.

Advertisement Account.

The moneys under the Advertisement and Annual Dinner Account have not been allowed to lie idle. A scheme for advertising the benefits of the society was agreed to, and a circular letter was drawn up. Five thousand circulars were printed, and three thousand were sent by post to gardeners in the following eleven counties: Berks, Bucks, Essex, Hants, Herts, Kent, Middlesex, Norfolk, Suffolk, Surrey, and Sussex. In addition, bundles of from sixty to one hundred circulars have been sent to the secretaries of gardeners' debating societies at Bath, Bristol, Birmingham, Edinburgh, Exeter, Isle of Wight, Newport (Mon.), and Stirling; and though the results so far have not been so satisfactory as the committee reasonably expected, the effort has not been fruitless. The total expenditure was £10 8s.

The Annual Dinner.

A successful festival dinner was held at the Waldorf Hotel, Aldwych, W.C., on October 3, when Edward Sherwood, Esq. (of Messrs. Hurst and Son, wholesale seed merchants, Houndsditch, E.C.), occupied the chair. He was supported by his father, N. N. Sherwood, Esq., V.M.H., who is well known to the members of the U.H.B.P.S. as the founder of the society's convalescent fund, and who made a speech in which he promised to continue his annual contributions to that fund, and strongly urged those members who may be recovering from an illness to make use of the provisions of the convalescent fund, as this was the surest way to complete recovery. There were about eighty present, a large number of them being strangers, and the Chairman expounded the benefits of the society in an able manner. He himself became an honorary member, and very generously provided a most excellent and enjoyable musical entertainment. The tables were again tastefully decorated with flowers and plants, which were kindly provided by Messrs. James Veitch and Sons, Lim., Messrs. H. Cannell and Sons, Mr. Riley Scott, and other friends.

This annual function was thoroughly enjoyable.

Widows and Orphans.

Reference was made in the last annual report to the suggestion brought forward at a recent annual general meeting for the establishment of a fund to provide for funeral expenses in case of any member who might have the misfortune to lose his wife by death. Actuarial advice was obtained upon this matter, with the result that as there were so many points of far-reaching importance involved, it would not be wise to lay any propositions before the members at the present time. The matter is, therefore, indefinitely in abeyance.

The committee would again direct attention to the benefits of the Royal Gardeners' Orphan Fund, and begs support wherever possible for the orphans of deceased members of the U.H.B.P.S. Much good can be done by co-operative voting. A subscription of 5s per annum entitles a subscriber to one vote at each election, and if a large number were to subscribe, the election of children of deceased members to the benefits of the fund would be practically assured.

State Insurance.

A keen watch has been kept on all the statements and reports in the Press in regard to the tentative proposals of State insurance against sickness, and the committee has been in communication with the Chancellor of the Exchequer twice on this matter. A report and balance-sheet for 1909 was also forwarded to the Chancellor, with a request that the committee be kept informed of any developments.

Benefits of Membership.

The many benefits attaching to membership of the society are well known to the members themselves, although not all of them, as already pointed out, are taken full advantage of. But if the society is soon to hold that large place in the horticultural world it is meant to fill, then there must be greater effort on the part of private members. In return for a payment of 9d. per week a member receives 18s. per week for six months if continuously ill for that period, and 9s. per week for a further six months if still ill (12s. and 6s. respectively if the subscription is 6d. per week. In cases of chronic sickness, 6s. and 4s. per week respectively are granted, and, should a member be unable to follow his employment after attaining the age of seventy years he receives a sum of not less than 5s. per week. After reaching sixty years of age a member may withdraw a sum equal to double the amount of the interest on his deposit account in any one year, and thus, in times of stress be able, in many cases, to pay his contributions to the society from the amount standing to his personal account in the books of the society.

In short, the society provides for sickness, makes provision for chronic illness, renders aid to the distressed, credits each member with a due proportion of the surplus funds, helps the convalescent, and cares for the feeble and aged. Every member should act as a missionary of the society, and continually preach the gospel of thrift and self-help with intent to secure new members. The financial stability of the society is beyond question, as it has now £38,800 invested.

In conclusion the committee begs once

more to acknowledge the kindness of those who, as honorary or life members, or in other ways, assist the society and help to extend its usefulness and sphere of influence.

The Horticultural Club.

"FUNGI."

On Tuesday, the 14th ult., at the Hotel Windsor, the members of the Horticultural Club had their usual monthly dinner, and on this occasion were associated with a considerable number of the provincial secretaries of the International Horticultural Exhibition of 1912, who were entertained in that connection. After the dinner, at which Mr. Gurney Fowler presided on behalf of both bodies, Mr. A. D. Cotton, of the Kew Herbarium, gave a most interesting lecture on "Fungi," illustrated by a large number of lantern slides. At the outset he explained that the three lower classes of non-flowering plants were the algæ or seaweed, the lichens or liverworts, and the fungi with which he proposed to deal. These were divided into an immense number of families, of which the mushrooms or agarics were the best known. These were distinguished by the innumerable spores they produced, being engendered on the surfaces of the thin plates which lined the cap, which was borne upon a stalk of some thickness, the common mushroom being the type of many different species. He threw this on the screen, and followed it up by specimens of many others, some edible and some very poisonous, the visible difference between the two being often only perceptible to experts. Some, as he pointed out, were parasites, deriving their sustenance from living matter, upon which they preyed, while others were content with dead matter (saprophytes), though in some cases these proved themselves capable of acting in both rôles. The parasitical ones were capable of destroying trees to a very great extent. Some of these could only obtain access to the living portion of a tree through a wound in the bark, which suggested the great advisability of covering such wounds as are caused by chopping and pruning with a good coat of tar. Others, however, attacked the roots, and these were much more insidious, being apt to infect neighbouring trees when infected roots reached them through the soil. Mr. Cotton then turned from the easily visible fungi to the immense horde of minute ones which constitute the "moulds," and many of the diseases of plants, and in some cases of animals; while in the case of Stilton and other cheeses they have an attraction for the expert in flavours, which a good microscope might do something to modify. Minute, however, as these fungi are, they are often extremely beautiful when highly magnified, their groups and clusters of spores being charmingly arranged and fashioned. It is a curious fact that with many of these two kinds of spores or reproductive bodies are produced, the one capable of spreading broadcast during the summer and growing into fresh colonies at once, while later on, resting ones are produced, which lie dormant through the winter, and only start into activity when the growing season recurs. Slides were shown of these resting spores on persistent fruit and seed-vessels, and on the wood, and it was demonstrated that a drastic destruction of such "depôts" in the winter would go far to reduce destruction later on. As, however, the lecturer pointed out, the destruction brought about by these minute fungi, and by some of the larger ones has its beneficial side. It is part and parcel of the great compensating scheme of nature, which, when death occurs, restores the materials to the earth for re-use, instead of merely piling it up in a non-utilisable form. Every dead leaf is at once seized upon by fungi, and decomposed into its original elements of carbon and carbonic acid gas, the residue constituting the best possible food for a future generation. The very air teems with the spores of these scavengers, and, given sufficient warmth and moisture and a supply of suitable nourishment, a colony, or colonies, is bound to arise from deposited spores, and in a very short time the ashes of the departed are reconverted into the bodies of the living, and the cycle is recommenced.

A very hearty vote of thanks concluded the meeting.

Bournemouth Gardeners' Association.

On Tuesday, March 21, Sir Daniel Morris, K.C.M.G., gave a very interesting and instructive lecture on "The Royal Horticultural Society," before a good attendance of members, and of the public. The lecture was illustrated by lantern slides; many very excellent photographs of exhibits at the Horticultural Hall, Westminster, and views in the gardens at Wisley were shown and highly appreciated. The president, J. H. Ralph Smythe, Esq., J.P., occupied the chair.

Sir Daniel Morris, in his opening remarks, first made a brief reference to the growth of horticulture during the past fifty years, to the advances made in science all over the world, and to the growth of trade in connection with horticulture. He spoke of the good influence of the Royal Horticultural Society upon associations in the provinces, such as the one at Bournemouth. Sir Daniel reminded his audience that the Royal Horticultural Society was started in 1804, but at that time it did not bear the Royal title. He referred to the work of Mr. Wedgwood, of pottery fame, who, with a few friends, met in a house in Piccadilly to discuss the question of forming a society to encourage the cultivation of plants, etc.; to the charter being granted in 1809; to the first president (the Earl of Dartmouth); to Mr. Andrew Knight, the next president; the late Prince Consort, and others; and to the striking of the Knightian medal, in memory of Mr. Knight. The lecturer dealt with matters connected with the society while it was at Kensington, its sixty years at Chiswick, and now its gardens at Wisley. He paid a tribute to the work done by the Rev. W. Wilkes, and his selection and introduction of the Shirley poppies; and made graphic reference to the struggles of the society in the past, and to its flourishing condition at the present time. The centenary of the society in 1904, the building of the hall at Vincent Square, Westminster, the gardens of Mr. G. F. Wilson at Wisley, and the support given to the society by Sir Thomas Hanbury, who purchased the Wisley gardens for its benefit, were matters ably dealt with by Sir Daniel.

He also referred to the special work of the society in sending out men in the twenties and thirties to collect plants from all parts of the world, the plants being cultivated first at the society's gardens and then distributed through its Fellows to the public generally. The lecturer said the council had instituted examinations for young men in two grades, those under eighteen years of age, and those above that age; also for teachers in charge of schools, and for those employed in public parks and gardens. In the gardens at Wisley every effort was made to establish plants and grow them under conditions as nearly natural as possible, and he urged his hearers to leave the formal and adopt the informal and natural way of growing plants, even in the smallest gardens.

Splendid exhibits of cinerarias and deutzias were staged by Messrs. C. Pearce and G. Heath respectively. One plant of Cineraria stellata, shown by Mr. Pearce, was 4ft. high with a head of flowers 4ft. across; the leaves touched the floor. Both the lecturer and chairman received hearty votes of thanks at the close of the meeting.

Reading Gardeners' Association.

The usual fortnightly meeting of this association took place in the Abbey Hall on Monday, March 20, when Mr. Alderman Parfitt presided over a large gathering of members.

The lecturer for the evening was a former member of the association, Mr. W. P. Bound, one of the chief authorities on orchid growing in the country, his subject being "Potting and Watering Orchids." When it is stated that for many years Mr. Bound had charge of Sir Jeremiah Coleman's world-renowned collection of orchids at Gatton Park, it will be readily understood why the lecturer proved such an attraction. It would be impossible to deal with the subject within the scope of this report, but it will suffice to say that Mr. Bound, in the time at his disposal gave his audience the full benefit of his wide experience in the treatment of these wonderful flowers. First dealing with cattleyas and lælias and their hybrids, the lecturer gave the members the benefit of his valuable advice with regard to potting, stating, too, the ingredients of the compost proved by him to give the most satisfactory results. Watering and the withholding of water, the lecturer declared, was the most important factor of all, and oftentimes the cause of the troublesome diseases to which orchids are subject. Dendrobiums (his favourites) were then taken up by Mr. Bound, odontoglossums following, and finally calanthes as being special favourites in the Reading neighbourhood

In the discussion which followed, Mr. Bound readily answered all questions put to him by the audience.

A vote of thanks, carried with great acclamation, concluded the meeting.

East Anglian Horticultural Club.

At the March meeting of this club a large number of members assembled, Mr. Lewis Smith, Shotesham Hall Gardens, presiding. Reference was made to the death of Mr. George Daniels, one of the founders of the club, and a silent vote of condolence was passed. The main subject for the evening was an essay competition open to under gardeners only, upon "The Cultivation of Vegetables." Four papers were received, each of which dealt with the subject in a practical style. Deep cultivation, rotation of crops, seed sowing, pricking out, etc., all being dealt with. Certain individual methods of culture came out here and there. The judges awarded prizes as follows: First, Mr. E. Hales, Heacham Hall Gardens; second, Mr. G. R. Wright, Wroxham Hall Gardens; and third, Mr. Robt. Graveling, Thorpe, Norwich. The papers were followed by a

FALMOUTH SPRING FLOWER SHOW.
THE SHOW OF THE CORNISH RIVIERA.
To be held April 19th and 20th.
To be opened by their Royal Highnesses Prince and
Princess Alexander of Teck.
First-class Band and Programme.
Free accommodation to the Trade.
Schedules and full particulars,
R. E. GILL,
Hon. Secretary,
Falmouth.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

keen discussion, and many knotty or difficult points in vegetable culture were threshed out.

The weather report for the past month supplied by J. H. Willis, Esq., went to show that the month had been exceptionally mild, with just the exception of the first few days.

The standard of the exhibits was well kept up, and a fine display staged. Mr. W. Sheesmith had a fine cymbidium and a good assortment of Lenten roses from the gardens of F. W. Harmer, Esq., Cringleford, where he is in charge. Mr. F. J. Endersby, gardener to J. H. Gurney, Esq., Keswick Hall, exhibited a grand example of cyclamen, the plant carrying 69 perfect white blooms. Mr. W. Laws, gardener to G. E. White, Esq., Eaton, who is an enthusiast upon winter carnation culture, staged a nice bunch of blooms of leading varieties, and a plant with a profusion of flowers. The Secretary, Mr. W. L. Wallis, 12, Royal Arcade, Norwich, was busy during the evening enrolling new members.

Royal Horticultural Society.

The meeting at Vincent Square on March 28 was a full one. The tables were arranged the full length of the hall, save for spaces at either end for the people to walk, but there was no central cross space on this occasion, so that one had to travel further than usual to reach exhibits half-way down the hall. There was an excellent attendance, and, though the crowd was scarcely so dense as on March 14, the crush was very great. The use of the door under the music gallery, in accordance with the suggestion we made a fortnight since, greatly facilitated the exit of visitors. Daffodils, hardy flowers, and orchids were the feature of the show.

FLORAL COMMITTEE.

Messrs. Heath and Son, Cheltenham, occupied one corner of the hall, filling it with a rock garden. Alpine shrubs formed a background for a very wide range of primulas, saxifragas, heaths, violas, narcissi, and other early spring flowers.

Zonal pelargoniums were finely shown by Messrs. H. Cannell and Sons, Swanley, and the fine spikes of large brilliant blooms made a great blaze of colour.

Mr. H. Hemsley, Crawley, had a rock garden exhibit very daintily set up. Small alpine and flowering shrubs were used as a background for anemones, saxifragas, primulas, aubrietias, etc., etc.; Linaria triornithophora, Viola velutina, Erigeron Roylei, and Rhododendron racemosum were other interesting things.

Messrs. Paul and Son, Cheshunt, contributed a group of roses, chiefly polyantha varieties, in pots: Aennchen Muller, Tip Top, Orleans Rose, Unser Peti, Cyclops, Jeanne d'Arc, Miese, Gustel Meyer, and Excellency von Schubert were the leading varieties shown.

A large cream-ground hippeastrum with red flaming, named The Prior, was shown by Mr. H. Edwards, Norton Priory, Selsey-on-Sea; the flower was of great size.

Ourisia macrophylla, with pale blush-pink flowers, from the New Zealand Alps, was contributed by the Burton Hardy Plant Nurseries, Christchurch, Hants.

A pretty exhibit of perpetual carnations was set up by Messrs. Young and Co., Hatherley, Cheltenham, and leading varieties were the new crimson Duchess of Devonshire, R. Whitcombe Riley, Cheltonia, Enchantress, Hon. Lady Audley Nield, Mikado, and Rose Doré.

A large exhibit of hardy plants from Messrs. Barr and Sons, Covent Garden, W.C., contained a selection of Lenten roses, hardy primulas, Tulipa Kaufmanniana, chionodoxas, lovely crocuses, the exquisite little Anchusa myosotiflora, with blue forget-me-not like flowers, saxifragas, fritillarias, and the brilliant Erica carnea

Gorgeous amaryllis, extra fine varieties of imantophyllums, the cactus-flowered cineraria Feltham Beauty, blue and pink-flowered Indian azaleas, a fine strain of Primula obconica in various colours, and the fragrant Boronia megastigma and freesias, were all staged in quantity by Messrs. Jas. Veitch and Sons, Chelsea, the whole display filling a considerable space, and making a very fine effect. In another part of the hall the Chelsea firm showed their excellent strain of cyclamen, and presented finely-grown batches of the different colours. A glorious group of forced shrubs also came from Messrs. James Veitch and Sons, Lim., Chelsea. The standard wistarias were the leading feature; they were splendidly flowered and the centre of admiration from the visitors. Rhododendron The Countess was also in fine form; while viburnums, Azalea mollis, and Erica Veitchi all added to the beauty of the group.

Messrs. Bakers, Wolverhampton, presented a pretty group of hardy flowers, and notable features of this exhibit were the batches of Primula rosea, P. Mrs J. H. Wilson, Adonis amurensis, Androsace coronopifolia, Incarvillea grandiflora, Cypripedium spectabile, and the rich purple Viola gracilis.

Fortune's Yellow rose was well shown by Mrs. Harvey, Farnham Common, Slough, and the long sprays of flowers were greatly admired.

Mr. James Box, Lindfield, Sussex, contributed a rock garden display, and furnished his bold design with groups of daffodils, blue primroses, aubrietias, Anemone fulgens, Erica carnea, Primula rosea, Tulipa Greigi, crocuses, and azaleas.

Messrs. W. Cutbush and Son, Highgate, presented a large exhibit of perpetual carnations, their vases of Mrs. Fortescue, White Perfection, Lady Coventry, Winsor, and Defiance attracting a great deal of attention. They also put up a large display of forced flowering shrubs, with batches of hepaticas, anemones, iris, primulas, etc.

Polyanthuses and primroses in variety, very free and vigorous, were set up by Messrs. G. and A. Clark, Dover, who also staged Primula rosea, P. malacoides, Viola gracilis, St. Brigid anemones, etc.

An attractive exhibit of hardy flowers came from Messrs. G. Jackman and Son, Woking, and here some of the prettiest things were Erica carnea, Cyclamen ibericum, Erodium pelargonifolium, Megasea crassifolium, Tulipa Griegi, Morisia hypogæa, Draba aizoides, Lithospermum Heavenly Blue, and the white form of Muscari conicum.

A glorious lot of perpetual carnations from Mr. H. Burnett, Guernsey, was a great attraction. The flowers were of superb size and colour, and their arrangement excellent; Marmion, Mrs. H. Burnett, Beacon, Mrs. Tatton, Mikado, R. F. Felton, Mrs. C. F. Raphael, Countess of March, and White Enchantress were varieties that especially attracted our attention.

Small clematises, in 48-sized pots, each with six to eighteen blooms, were very elegant as shown by Messrs. H. B. May and Son, Edmonton; especially good were the varieties Mrs. Quilter, Miss Bateman, and Nellie Moser; choice plumose ferns completed the display.

The hardy flowers from Messrs. T. S. Ware, Lim., Feltham, included such beautiful things as Androsace Laggeri, Soldanella alpina, Iris purpurea grandiflora, Primula muralis, P. denticulata, double primroses, Trillium nivale, Dicentra cucullaria, and other dainty little things.

In the bold rock garden set up by Messrs. J. Cheal and Sons, Crawley, choice things were crimson primroses, Epimedium nivea, Primula japonica, Morisia hypogæa, Gentiana verna, Viola gracilis and Olearia stellata.

Brilliant rhododendrons of the R.arboreum type made a blaze of colour in the group of hardy flowers contributed by Mr. G. Reuthe, Keston. Primulas were good in this exhibit, and so were the saxifragas, Narcissus cyclamineus, Tecophylea cyanocrocus with its bright blue flower, the golden Ranunculus insignis, Soldanella montana, Iris Willmottiana, etc.

In the large group submitted by Messrs. Stuart Low and Co., Enfield, the acacias were a good feature, while the Glory Pea, Clianthus puniceus, was a great attraction. Gerbera hybrids, the white long-flowered hydrangea Madame Moullière (A.M.), and the perpetual carnations added to the merits of the exhibit. Among the latter the best things were Lady Alington, Marchioness of Linlithgow, Black Chief, Colossus, White Perfection, O. P. Bassett, and Roseate Dawn.

Messrs. R. and G. Cuthbert, Southgate, had a splendid group of forced shrubs, the standard specimens of weigelas being especially good, as were also the lilacs and laburnums, the groundwork being formed with well-flowered plants of Viburnum opulus and azaleas of the mollis and rustica type, the whole group being most tastefully arranged.

From Mr. L. R. Russell, Richmond, came a fine group of forced shrubs, which included large plants of Forsythia suspensa, standard Azalea mollis, lilacs in variety, and some well-flowered plants of clematises, which included Nelly Moser, President, Mrs. G. Jackman, and The Queen, all in fine form. Deutzias and Franciscea calycina floribunda were also quite attractive, as were also some dwarf Azalea indica.

The Guildford Hardy Plant Nursery occupied a table with hardy flowers, all displayed in pots. The primulas, Viola gracilis, anemones, and saxifragas were the best features, but mention should also be made of the hellebore hybrids, and Megasea Milesi and M. ligulata var. Leichtlini, which were in fine condition.

A very bright and attractive exhibit of hardy flowers came from Mr. M. Prichard, Christchurch, Hants. The collection was particularly rich in primroses, especially the double-flowering forms, also broad masses of Viola gracilis, aubrietias, and anemones, while the background was filled with suitable flowering shrubs and acers.

The Burton Hardy Plant Nurseries, Christchurch, were represented by a pretty collection of alpines, tastefully arranged with rock and moss. Primulas were beautifully shown, as were also Viola gracilis, saxifragas in variety, and a number of aubrietias. Mr. H. C. Pulham, Elsenham, Stanstead, Essex, also contributed an exhibit of rock plants, which were arranged naturally in a series of stone terraces.

From Messrs. R. Wallace and Co., Kilnfield, Gardens, Colchester, came a charming exhibit of rock and alpine plants. The tulips were very attractive, and included T. Clusiana, T. præstans, T. Kaufmanniana aurea, among others. The aubrietias were well displayed, as were also the saxifragas and Viola gracilis.

A fine bank of roses in a cut state was presented by Mr. G. Prince, Oxford. The flowers were beautifully fresh and bright, the chief varieties being Lady Roberts, Mrs. Alfred Westmacott, Madame Jules Gravereaux, Mrs. W. J. Grant, and Ards Pillar.

Mr. H. N. Ellison, West Bromwich, had a beautiful display of Gerbera hybrids, arranged in bamboo stands with Asparagus plumosus. The colours were exquisite, and attracted much attention from the visitors. The rest of the display was made up with various forms of nephrolepis, all in perfect condition.

Hardy plants from Mr. Clarence Elliott, Six Hills Nursery, Stevenage, were arranged most naturally, the best features being Morisia hypogæa, with its bright yellow flowers, and scillas in variety. Primulas were in fine form, while masses of saxifragas were also quite a feature.

Mr. C. Englemann, Saffron Walden, had another really fine exhibit of carnations. The stands of Carola, Enchantress, and Rex being very fine, while the best vases were Beacon, Rose Doré, and J. W. Riley

Messrs. G. Mount and Sons, Lim., Canterbury, staged splendid examples of the White

Killarney roses, possibly the best examples yet seen of this variety; also Lady Hillingdon in magnificent colour, while the new variety, Mrs. Geo. Mount, was in good condition.

Mr. S. Mortimer, Swiss Nursery, Farnham, staged a large collection of carnations in vases, the most prominent being Mrs. H. Burnett, Carola, Royal Purple, Pink Delight, and Victory.

Messrs. R. F. Felton and Sons, Hanover Square, staged vases of a carnation named Empire Day (A.M.), a delightful pink variety; Britannia, Union Jack, Queen Mary, and British Queen.

From Messrs. William Paul and Sons, Waltham Cross, came an exhibit of roses in pots, which included well-flowered plants of Sylvia, Souvenir de Gustave Prat, L. Chaurè, and good examples of Banksian Yellow.

From Messrs. R. Gill and Sons, Falmouth, came a large collection of Rhododendron arboreum hybrids, which represented a wide range of colours. Some fine specimens of Camellia reticulata were also noted, while the new hardy Primula Winteri was in splendid form, and attracted much attention.

ORCHID COMMITTEE.

Dendrobium Wardianum candidum, smothered in flowers, from which the purple colouring of the type was absent, was well shown by Mr. Jas. Hudson, V.M.H., gardener to Leopold Rothschild, Esq., Gunnersbury House, Acton.

Mr. J. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford, sent the beautiful Odontoglossum Wilckeanum J. Gurney Fowler, and Odontioda Lambeauiana Fowler's var.

Odontoglossum Leonidas, with golden, brown-marked flowers, was contributed by Mr. de Barri Crawshay, (gardener, Mr. Stables), Rosefield, Sevenoaks.

Mr. Hale, gardener to S. Larkin, Esq., Haslemere, Surrey, brought examples of Cattleya Trianæ, Phalænopsis Schillerianum, Vanda suavis, and a few odontoglossums and cypripediums.

Mr. G. Cooper, gardener to H. S. Leon, Esq., Bletchley Park, Bucks, sent Cypripedium Deedmanianum, and Mr. G. Day, gardener to H. S. Goodson, Esq., Fairlawn, Putney, exhibited Sophro-cat-lælia Olive, Fairlawn var.

Odontoglossum Clytie, with long, branching spikes of small velvety crimson-purple flowers, was shown by Mr. R. G. Thwaites, Streatham: it is the result of a cross between O. Edwardi and O. Pescatorei.

The new Dendrobium Boltoni and a neat plant of D. speciosum Bancroftianum, were sent by Mr. W. Bolton, Wilderspool, Warrington.

A very interesting display of orchids was made by Mr. Collier, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate. Very conspicuous were the long drooping spikes of Odontoglossum Thompsonianum, the superb solid red Odontioda Vuylstekeæ var. Lady Colman (F.C.C.), Odontoglossum Queen of Gatton, O. Lady Roxburgh, and the white Dia-cattleya Colmanæ.

The bold Odontoglossum facetum Swietenicolor, from Mr. W. H. White, gardener to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, gained an A.M.; the colour is deep mahogany-red with creamy margins.

Some delightful orchids were brought from Oakwood, Wylam-on-Tyne, by Mr. H. J. Chapman, gardener to Mrs. Norman Cookson, and all were home-raised seedlings. Especially good were Odontioda Cooksoniæ Oakwood var., Odontoglossum splendidissimum, O. percultum, O. Pescatorei Cooksonianum, O. eximium, O. Titania, O. excellens, and Cypripedium Northumbria, the latter a cross between C. Chamberlainianum and C. Godefroyæ leucochilum.

Messrs. Armstrong and Brown, Tunbridge Wells, presented a beautiful group of orchids, consisting largely of Dendrobium nobile virginale, Odontoglossum crispum, O. nævium, O. Adrianæ, O. Wilckeanum, O. ardentissimum, Brasso-cattleya Leemanæ, Lælio-cattleya Myra, Brasso-lælia Veitchi, Lælia Gwennie, and Masdevallia Shuttleworthi.

The orchids exhibited by Messrs. Charlesworth and Co., Haywards Heath, included grand plants of Miltonia spectabilis, Cynorchis Kewensis, Odontioda Bradshawiæ, O. Diana, O. Craveniana, the charming little Zygo-colax Charlesworthi, Lælio-cattleya Dominiana, Cattleya Empress, Odontoglossum ardentissimum, O. crispum, O. Phœbe, Brasso-cattleya Veitchi var. Queen Alexandra, and Phaius Norman, and the beautiful Cymbidium insigne.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, contributed Dendrobium Wardianum, Oncidium concolor, the fragrant Cattleya Schroderæ, Odontoglossum blandum, O. crispum, Renanthera Imschootiana, and several cypripediums.

A very handsome group of orchids from Messrs. Sander and Sons, St. Albans, was remarkable for the brilliance of the odontoglossums, such as O. ardentissimum, O. eximium Monarch, O. crispum Prince George, O. amandum citrinum, and O. eximium Empress. Brasso-cattleya Thorntoni was superb, and Lælio-cattleya Peetersi, Cattleya Trianæ varieties, the quaint and showy little Odontioda ignea (A.M.), and Scuticaria Hadweni were other good things.

Messrs. Hassall and Co., Southgate, put up some good plants of Oncidium concolor, Cymbidium eburneum, C. eburneo-Lowianum, C. Lowianum concolor, the brilliant Lælio-cattleya G. S. Ball, Dendrobium Brymerianum, and Odontoglossum Rolfeæ.

Mr. E. V. Low, Haywards Heath, sent the beautiful Cattleya Schroderæ The Kaiser—curiously enough a delicate blush variety; Cattleya Trianæ, Brasso-cattleya Langleyense, Dendrobium nobile virginale, D. pallens, and the rich yellow D. Chessingtonense.

DAFFODIL COMMITTEE.

Robert Sydenham, Lim., Tenby Street, Birmingham, contributed a small collection of choice daffodils, flanked by lily of the valley, spiræas, etc., grown in moss fibre. Among the daffodils we noticed such good things as Thos. Baricke, a new cream-white giant Leedsi, Homespun, Ptarmigan, Blood Orange, Tomtit, White Lady, Evangeline, and Firebrand.

Tulips were extensively shown by Messrs. R. H. Bath, Lim., Wisbech, and these were displayed in fancy bowls, in fibre, Brunhilde, Vermilion Brilliant, King of Yellows, Van Roozen, Rose Gris de Lin, and Couleur Cardinal were well shown. The poetaz Narcissus Aspasia was particularly well represented, and there were good flowers also of Mdme. de Graaff and other good things.

Messrs. Cartwright and Goodwin, Kidderminster, put up a delightful exhibit of choice daffodils, arranging these with isolepis, and edging the display with Muscari conicum Heavenly Blue. Very pretty were the flowers of White Nectarine, White Lady, Rising Sun, Alice Knights, Southern Star, Dorothy Pearson, the bold Ajax variety Master of Balliol, Evangeline, Mrs. H. J. Veitch, Barcarolle, Ayacanora Circlet, and Scarlet Eye.

A small group of beautiful daffodils, practically all new seedlings, was submitted by Mr. Alex. Wilson, Shovell, Bridgwater; very few were named, but Beryl, a rich yellow variety, with a round orange cup, exquisitely frilled; we hear that this wonderful variety was obtained by crossing N. cyclamineus with the poet's daffodil. No. 362, a golden cyclamineus hybrid of good size; No. 598, a very big, flattish-crowned incomparabilis variety was another lovely thing, with creamy perianth and golden cup. It was a feast of good things for the daffodil specialist.

Mr. F. Lilley, Guernsey, brought over a small group of daffodils, the leading varieties in his display being Silver Spur, Glory of Nordwyk, King Alfred, Stromboli, Murillo, and Mrs. W. T. Ware, but all the flowers were a trifle small.

From the Lissadell Bulb Farm, Sligo, came some fine daffodils, good in size and in colour. Very fine were the bunches of the white Mrs. Robt Sydenham, Homer, Henry Irving, Judge Bird, Flambeau, Sir Horace Plunkett, Rance, Argent, King Alfred, Golden Bell, and the lovely Whitewell.

Messrs. Barr and Sons, Covent Garden exhibited a quite large collection of daffodils and put up a very bright group. Very charming were the vases of King Alfred, Alice Knights, Fairy Queen, Fireflame, Sunrise, Homespun, White Slave, Lord Roberts, Sir Galahad, Victoria, Queen of the North, and The Sisterhood.

FRUIT AND VEGETABLE COMMITTEE.

Messrs. Sutton and Sons, Reading, exhibited a beautiful lot of cabbages, the heads fresh and of excellent size for the time of year, thus demonstrating the earliness of the varieties which were Sutton's April, Flower of Spring, and Harbinger.

Mr. Wm. Poupart, Marsh Farm, Twickenham, showed rhubarb from the open ground; the varieties named Daw's Champion and Hawkes' Champagne, were well advanced, and had been yielding sticks for about a month, whereas other varieties shown were not yet fit to pull under similar cultural conditions; some excellent sticks of forced Daw's Champion were also contributed.

CERTIFICATES AND AWARDS.

First-Class Certificate. — To Odontioda Vuylstekeæ Lady Colman, from Sir Jeremiah Colman, Bart. (gardener, Mr. Collier), Gatton Park, Reigate..

Award of Merit.—To Odontoglossum facetum Swietenia-color, from Sir Trevor Lawrence, Bart. (grower, Mr. W. H. White), Burford Lodge, Dorking; to Odontioda ignea, from Messrs. Charlesworth and Co., Haywards Heath; to Rhododendron Mrs. Fitzgerald, from Miss Mangles, Seale, Surrey; to Carnation Empire Day, from Mr. Smith, Enfield; to Hydrangea Mdme. Moullière, from Messrs. Stuart Low and Co., Bush Hill Park, Enfield.

MEDALS.

Gold.—To Messrs. Jas. Veitch and Sons, Chelsea, for greenhouse plants and forced shrubs.

Silver-Gilt Flora. — To Messrs. Charlesworth and Co., Haywards Heath, for orchids.

Silver-Gilt Banksian.—To Mr. H. Burnett, Guernsey, for carnations; to Messrs. Wm. Cutbush and Son, Highgate, for carnations and hardy flowers; to Messrs. Cartwright and Goodwin, Kidderminster, for daffodils.

Silver Flora.—To Messrs. Armstrong and Brown, Tunbridge Wells, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Mrs. Norman Cookson (gardener, Mr. H. J. Chapman), Oakwood, Wylam-on-Tyne, for orchids; to Sir Jeremiah Colman, Bart. (gardener, Mr. Collier), Gatton Park, Reigate, for orchids; to Mr. Alex. Wilson, Bridgwater, for new daffodils; to Messrs. Barr and Sons, Covent Garden, for daffodils; to Messrs. R. H. Bath, Lim., Wisbech, for tulips and daffodils; to Messrs. Stuart Low and Co., Enfield, for greenhouse plants and carnations; to Messrs. R. and G. Cuthbert, Southgate, for forced shrubs; to Mr. Maurice Prichard, Christchurch, for hardy flowers; to Mr. G. Reuthe, Keston, for hardy flowers.

Silver Banksian.—To Messrs. H. B. May and Sons, Edmonton, for ferns and clematises; to Mr. George Mount, Canterbury, for roses; to Mr. George Prince, Longworth, for roses; to Messrs. Hassall and Co., Southgate, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to S. Larkin, Esq. (gardener, Mr. Hale), Haslemere, for orchids; to Mr. E. V. Low, Haywards Heath, for orchids; to Sir J. Gore Booth, Lissadel, Sligo, for daffodils.

Bronze Flora.—To Messrs. Barr and Sons, Covent Garden, for hardy flowers; to Messrs. G. and A. Clark, Dover, for hardy flowers; to Mr. W. H. Ellison, West Bromwich, for gerberas and ferns; to Mr. C. Engelmann, Saffron Walden, for carnations; to Messrs. R. Gill and Sons, Falmouth, for rhododendrons and primulas; to Messrs. Heath and Son, Cheltenham, for alpines; to Messrs. R. Wallace and Co., Colchester, for hardy plants; to Messrs. T. S. Ware, Lim., Feltham, for hardy flowers.

Bronze Banksian. — To Messrs. J. Cheal and Sons, Crawley, for rock garden; to Mrs. Harvey, Slough, for roses; to Mr. L. R. Russell, Richmond, for forced shrubs, etc.

CANARY GUANO

"THE BEST IN THE WORLD."

There is no Fertilizer that gives such good all round results as CANARY GUANO. It is used in the King's Gardens, and by leading Amateurs and Trade Growers all over the Country. A post card to the Manufacturers will ensure full particulars.

DARLEY DALE, DERBYSHIRE.

Birmingham Gardeners' Association.

On Monday, March 20, at the fortnightly meeting, with Mr. C. H. Herbert in the chair, there was a very good attendance to hear Mr. Wm. Hales, a former lecturer and at one time a student under Mr. W. B. Latham, at the Botanical Gardens, Edgbaston. In his preamble, Mr. Hales adverted to the pleasure it used to give him to join in the essays for the prizes offered by the committee, in rivalry with his fellow-student and friend, Mr. E. H. Wilson, of China floral research fame.

The subject of Mr. W. Hales's essay was "British Plants in the Garden," and he gave details of the life-history and habitats of the plants, as well as their decorative attributes. In the discussion which followed, Messrs. C. H. Herbert, Wm. Spinks, A. D. Christie, Alfred Cryer, Walter Jones, and Wm. Gardiner took part; several questions were asked, and were promptly responded to by Mr. Hales in appropriate terms, and to him a cordial vote of thanks was accorded.

At the close of the proceedings, when Mr. Hales was taking a cursory view of the invaluable collection of books in the association's book cases, he remarked to the librarian that he was tempted to break the eighth Commandment in respect of the twelve volumes of Sowerby's "English Botany."

Thunder heard on the afternoon of Wednesday, 22nd, from 3.30 p.m. to 5 p.m.

Snow fell from 8.30 a.m. to 9 a.m. on Saturday, 25th, and at intervals during the day.

FORTHCOMING ENGAGEMENTS.

SATURDAY, April 1.—Paisley Florists' Spring Show.
TUESDAY, April 4.—Truro Spring Show; two days.
Bournemouth Spring Show; two days.
Scottish Horticultural Association meeting.
WEDNESDAY, April 5.—Liverpool Spring Show; two days.
Royal Horticultural Society's general examination in Horticulture.
THURSDAY, April 6.—Linnean Society meets.
FRIDAY, April 7.—Kingsbridge Daffodil Society.
MONDAY, April 10.—United Horticultural Benefit and Provident Society, committee meeting.
TUESDAY, April 11.—Royal Horticultural Society; Daffodil Committee meets at 11.30; Fruit, Floral, and Orchid Committees at 12 o'clock; lecture at 3 p.m. on "The Origin and Structure of Aquatic Flowering Plants," by the Rev. Prof. G. Henslow, V.M.H.; Scientific Committee at 4 o'clock.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

OLD DENDROBIUM GROWTHS.—A.: The old growths sent will not flower again, and they may be cut away, but unless there is some special reason for doing so only those more than one season old should be removed. Give the plants every encouragement to grow freely by affording a high temperature, ample atmospheric moisture, and plenty of light, only shading lightly during the brightest and hottest part of the day. The present is also an excellent time for potting dendrobiums that have started well into growth, as new roots will be quickly made and enter into the new potting material.

JAPANESE MAPLES.—J. C., Epsom: Comparatively few of the beautiful little shrubs and trees grown under the collective title of Japanese Maples are propagated in this country. Quantities are imported annually from Japan, and kept in frames or a cool-house until the season is so far advanced that they may be planted out without fear of harm. So far as we can gather, the stock upon which these elegant-leaved and brilliantly-coloured varieties are grafted or budded is the wild and typical Acer palmatum. In this country budding would be best done in the summer, and grafting in the early spring. Most maples will propagate readily from layers.

WHITE - STEMMED BRAMBLES. — C. B. A., Carnarvon: Two species of rubus have white canes or stems. One of these, Rubus biflorus, is from the Himalayas; it is quite hardy and of free growth. When leafless it forms a striking feature in the landscape, as the stems are so white as to suggest they have been white-washed. The other species of similar stem character is R. leucodermis, from North-west America. This is not so good as R. biflorus, because its growth is less robust and the whiteness of the stems is less decided. R. neglectus, probably a natural hybrid, and R. occidentalis — the Thimble Berry of the United States, both have whitened stems, but neither can compete in this direction with R. biflorus.

OMPHALODES VERNA.—S. A., Chelmsford: Sandy soil in which there is a goodly proportion of leaf-mould suits this pretty little spring flower quite well. Its increase offers no special difficulties in gardens where it grows freely, and a good method of propagation is that of dividing the plants in late summer or early autumn, and setting out the little tufts of growth where they are to remain and flower. This work should be done as early in the autumn as possible, so that the divisions may have full opportunity for becoming well established before the winter sets in.

ORNAMENTAL GRASSES.—J. B. C., Wokingham: A few of the more ornamental grasses, i.e., those suitable for association with cut flowers, and which can be easily raised from seeds sown in the spring, will include Agrostis nebulosa, A. pulchella, Briza maxima, B. minor, Hordeum jubatum, Lagurus ovatus, Lamarckia aurea, Stipa pennata.

VARIETIES OF LILIUM AURATUM.—M. W. E., Pontefract: There are several varieties of the beautiful Golden-rayed Lily of Japan (L. auratum), and they are all distinct. Of course we do not refer to the natural variation of the type, such as is evidenced by the size of the flowers and the breadth of the petals. There are good and bad forms of L. auratum, just as there are good and bad forms of Dendrobium nobile, Cattleya trianæ, etc., etc. But we now refer to well-marked and named varieties, and the best of these are L. auratum platyphyllum, which has big, broad petalled and finely-spotted blooms; L. a. rubro-vittatum, with a deep wine-red band down each segment; L. a. virginale, a lovely white form, with a golden band down each segment, and with very faint spottings; and L. a. Wittei, unspotted, and pure white save for the light band of gold down the centre of each segment.

PLANTING AND STAKING SWEET PEAS.—E. M. C., Ryde.—You will find full particulars in regard to planting and staking sweet peas in "Sweet Peas and their Cultivation," to be obtained, post free, for 1s. 2d., from the GARDENERS' MAGAZINE Office, 148, 149, Aldersgate Street, E.C.

RULES OF THE NATIONAL VEGETABLE SOCIETY. — S. G., Towcester: Doubtless the National Vegetable Society has a full set of rules for its management and the guidance of the committee, but such are not published in the Schedule for 1911, nor do we find a set in the Schedule for 1910. If you write to the hon. secretary, Mr. E. G. Quick, Kelmscott, Harrow View, Wealdstone, he will enlighten you on the matter. The society will hold its exhibition at the Royal Horticultural Hall, Westminster, on Wednesday, August 30, and the comprehensive schedule extends to no fewer than seventy-nine classes. The society is doing excellent work by means of trials, etc., and is deserving of support; the minimum annual subscription is 5s.

NAMES OF PLANTS.

F. E. R., Godalming.—1, Primula frondosa; 2, Erica carnea; 3, Adonis vernalis.

V. R. E., Harrogate.—1, Hippophæ rhamnoides; 2, Cupressus Lawsoniana pendula.

C. A., Doncaster.—A very finely fringed form of a large-flowered strain of Primula obconica.

J. B., Missenden.—1, Anemone hepatica; 2, A. blanda; 3, Lachenalia Nelsoni; 4, Coprosma aurea.

H. S., Gillingham.—1, Oncidium concolor; 2, Dendrobium Brymerianum; 3, Oncidium ampliatum; 4, Azalea amœna; 5, not recognised.

S. N. W., Taunton.—1, Pelargonium denticulatum; 2, Begonia phyllomaniaca; 3, Saintpaulia ionantha; 4, Cytisus fragrans; 5, Adiantum reniforme; 6, Opuntia microdasys.

TRADE NOTES.

Weeds will soon begin to assert themselves on the garden paths, and they will have to be dealt with in some fashion; certain methods entail a vast amount of time and labour, while others are expeditious and equally effective. Among the latter methods the application of Eureka Weed Killer is worthy of attention, as it is an extremely useful preparation for the purpose, manufactured by Messrs. Tomlinson and Hayward, Lincoln, and supplied by all nurserymen and sundriesmen.

The usefulness of "Scrim" for the purpose of protecting the flowers of choice fruit trees from frost has been demonstrated over and over again. The light, soft, and strong "Scrim" supplied by Messrs. Robertson, Ireland, and Co., Dundee, appears to be ideal material, and would also serve to break up the direct rays of the sun if stretched over sweet peas, exhibition roses, and other flowers.

Garden labels multiply in kind as well as in number. We must have labels, and we want them, usually, as light and unobtrusive as possible. The latest bidder for popularity is the Ivo Permanent label, manufactured by the Permanent Printing and Process Co., 2, Sandland Street, Red Lion Street, Holborn. These labels are 2½ inches long by ¾-inch wide, and made of a material that resembles celluloid; they are either white or green, and the name of the rose, etc., is permanently printed in the label. An eyelet hole at one end of the label offers a ready means of attachment to the plant. The firm is stocking a very large set of rose names.

CATALOGUES RECEIVED.

CHARLESWORTH AND CO., HAYWARDS HEATH.—An admirable orchid catalogue, clearly printed, and the individual plants offered for sale are described and priced, while in all cases the parentage of hybrids is given.

J. T. WEST, TOWER HILL, BRENTWOOD.—This handy descriptive list is devoted to dahlias and contains a first-rate selection of show, cactus, pompon and single varieties, as well as a list of pæony flowered and decorative varieties, including a number of good things raised by Mr. West.

KETTEN BROTHERS, LUXEMBOURG.—A descriptive list of new roses for 1911, with illustrations of Rayon d'Or and Baronne Charles d'Huart.

BARR AND SONS, COVENT GARDEN, W.C.—A very useful and comprehensive catalogue of hardy perennials, alpines, aquatics, climbers, and ornamental shrubs, phloxes, irises, delphiniums, and other hardy florists' flowers are dealt with at considerable length.

NICHOLLS AND CLARKE, LTD., SHOREDITCH, LONDON.—The sanitary and general catalogue issued by this firm is one of the most remarkable we have seen. It is a stoutly bound large-quarto volume, finely printed on good paper, indexed, and extending to no fewer than 452 pages. Illustrations are to be found on every page, and range from the meanest drain tile to the most elaborate bath-room fixtures. Every sanitary requisite is included, while, of special interest to horticulturists are the pages referring to glass, cloches, paints, colours of all kinds, drains, and drain fittings, cisterns, water pipes, pumps, fountains, syringes, garden engines, valves, etc., etc.

WALTER VOSS AND CO., LIM., MILWALL, E.—A list of reliable requisites for use in the garden, orchard and greenhouse; fertilisers, spraying fluids, and spraying machines are leading features.

SCHEDULES RECEIVED.

FOREST HILL CHRYSANTHEMUM SOCIETY.—Eighth annual exhibition at St. James' Hall, Forest Hill, on Wednesday, Nov. 1.

DUNDEE HORTICULTURAL SOCIETY.—The floral fête will be held on Magdalen Green on August 31 and September 1 and 2. A schedule of 227 classes is provided.

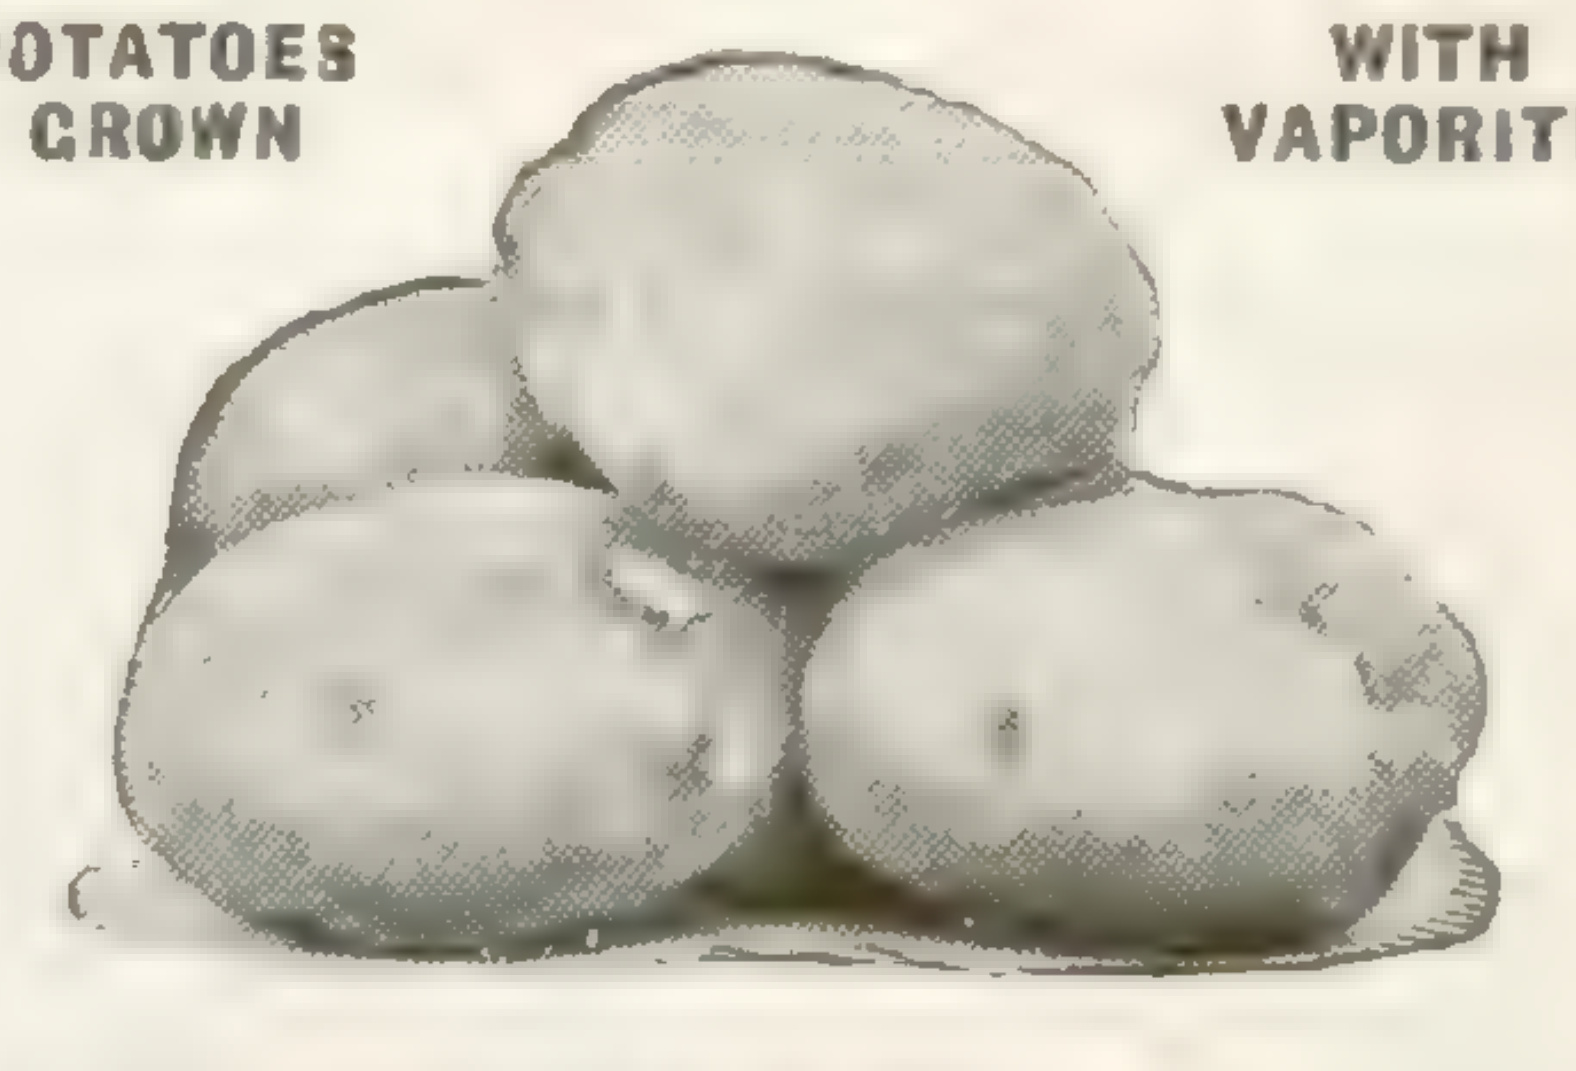
POTATOES GROWN WITHOUT VAPORITE.



VAPORITE

THE ORIGINAL SOIL INSECTICIDE should be dug in your garden at the rate of 1 lb. to 8 sq. yds. to ensure DEATH TO WIREWORMS.

WIREWORMS.

"The wireworms in a piece of old garden have entirely disappeared since treatment two years ago."—Mrs. V., Cornwall.

VERMIN.

"Our garden was full of vermin. Vaporite has cleared all out and all seeds grow luxuriously."—J. H. W., Worleston.

PRICES: Tins, 1½lbs., **9d.**; 7 lb. **2/-**; 14 lbs. **3/-**; 28 lbs. **4/6**, of all seedsmen. Casks: **7/6** ½ cwt.; **11/6** cwt., Carriage paid from your seedsmen or the Company.

The easiest, most economical, and speediest means of destroying soil pests in your garden is to use Vaporite. If it is dug well in before planting according to the directions in every tin, there is no fear of souring the ground, or soil insects spoiling your plants.

Vaporite is described fully in the interesting booklet, No. 45, sent free on request.

"CARRUSTICIDE."

The Best and Cheapest Remedy for Carnation Rust and other Fungoid Diseases.

A well-known Carnation Grower writes:

Dear Sir, The Nurseries, March, Cambs.

"During the 27 years I have been growing Carnations (Perpetual and American) I have tried most of the fungicides placed on the market, but yours is the best. It is a pleasure to see how "Carrusticide" catches hold of the Rust and destroys it. I should say your preparation will be extensively used when it is better known." Yours very truly,
GEO. CLARKE.

One gallon makes 25 gallons for spraying purposes—Price 3s. per quart, 7s. 6d. per gallon. Special quotations for larger quantities.

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

KELWAY'S LATEST SUCCESS.
GRAND PRIX AND GOLD MEDAL, Japan-British Exhibition, White City. Unanimous award of the International Jury to Kelway and Son for Pæonies, Delphiniums, Gladioli, Pyrethrums, etc.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

THE KELWAY ARTISTIC BORDER ensures a garden of enduring beauty from early Spring to late Autumn, with a minimum of cultivation, and without the trouble of constant digging or bedding-out. The plants composing the border are selected by experts, and include some of Kelway's improvements in Pæonies, Delphiniums, etc. Send dimensions of spaces to be filled, or for Kelway's "Gardens of Delight," 6d. The cost of this border is 15s. or 25s. for every 10 square yards. Carriage and package free for remittance with order.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

KELWAY'S MANUAL OF HORTICULTURE is the best of all Garden Books. 2s. post free, from KELWAY and SON, LANGPORT, SOMERSET.

NOW IS THE TIME TO PLANT KELWAY DELPHINIUMS, which have been improved almost out of recognition in the past twenty years. They produce plants ranging in height from four to eight feet, exceptionally hardy and with a rich profusion of choice blooms in all the shades of that valuable colour, blue.

Choice named varieties: 24s., 34s., and 58s. a dozen. Carriage and package free for remittance with order.

The celebrated present-day Delphiniums, and nearly all the best well-known varieties shown at exhibitions, originated in Kelway's Langport Nurseries.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

IRON and WIRE FENCING for GARDENS, Tree Guards, Gates, Arches, Espaliers, Rose Stakes, and Ornamental Garden Iron and Wire Work of every description. Send for Illustrated Catalogue, free. BOULTON and PAUL, Ltd., Manufacturers, Norwich.

THE POPULARITY OF XL ALL SPECIALITIES increases every year. All gardeners proclaim that nothing equals these celebrated preparations.

XL ALL NICOTINE VAPORISING COMPOUND, the gardener's favourite Fumigant, both Liquid and Cake.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

What is a Flower?

In these happy days for flower lovers we live amid such a wonderful wealth of bloom of such marvellous diversity of colour, make, habit, and form, that their very abundance distracts our attention from the underlying miracles which each and every one embodies. It is, for instance, practically entirely outside popular knowledge that every one of the blossoms is built up of modifications of the green leaves which accompany them, and that, although the utter transformation which we now behold is the outcome of æons of progress and incalculable small accumulated modifications, there is still a tendency to revert to the original foliar types in many flowers, as exemplified in green roses, dahlias, and innumerable malformations which every now and again crop up. From the poetical point of view, indeed, our query may be answered to the effect that a flower is really a nuptial bower contrived on the most æsthetic lines that Nature has been able to design. The rosy, golden, or azure chalice which we so much admire, is a complexly arranged cosy home, and ornate nest, within which a second generation is conceived, nurtured, and sheltered until, in the shape of a matured seed, it is capable of being launched into the world to play its part in the perpetuation of its tribe. Clearly, however, as some of the simplest and most primitive flowers are concerned, this all-essential office may be performed without any ornate adjuncts at all; and in the ferns, which preceded flowering plants proper, the requisites are so inconspicuous as to be absolutely microscopic, though equally efficacious in results. In those distant days the world was rich in both vegetable and animal life, and, so far as human comprehension goes, it got on very well in the absence of brilliant flowers, and might, therefore, have continued to reproduce its generations to this day without their aid. That inscrutable upward and onward creative impulse, however, which must have lain innate in the simplest primæval germ, was ever active, and, bit by bit, the microscopic pseudo flowers increased in size in some ambitious members of the plant world, the green colour varied into tints attractive to insects, for whose benefit no doubt honeyed lures were also developed, and ere long the modified leaves began to shape the tiny nests and tinier organs, and to contrive newer and newer modes of fulfilling their functions as varied environments and varied visitors of the insect world exercised selection on varied lines. A start once made, the brightest colour, or the largest flower, or accumulation of flowers, was the most visited, and set the most seed, and so, step by step, the world became filled with ever-increasing floral beauty, ranging from the simplest types to the most complex and resplendent. We must therefore regard the flower as the penultimate outcome of vegetative evolution. The ultimate outcome, of course, is the fruit, but, wonderful as every fruit, i.e., seed, is as representing the reproductive germ associated with a store of nutriment, and wonderful as are its accompaniments, in the shape of attractive pulp, protective shells, or what not, it cannot vie with the flower which preceded it in subtlety of contrivance, beauty of design, and æsthetic attractiveness. The object of these last has ceased to exist. The brilliant petals fade and drop, as a rule, very speedily, so soon as they have lured the entomological Cupids to the bower they have formed, and secured a return for the nectar they have provided. These colours in themselves are marvels. No mind can grasp the subtlety of selection which lies within the floral cells, and which enables them to break up the sunbeam into its constituent tints, as it does, retaining or absorbing some, and throwing off the rest, to convey to our eyes the particular tint in which we rejoice, for, strange to say, we can only see the colour which is rejected, and never the one which is sifted out and retained. Many flowers are multicoloured, and within these cells, in definite designs and places, we may detect by the microscope, as Mr. E. Bunyard has demonstrated, that we see different tints by virtue of different arrangement of cell contents, as much as by the different tints of the contents themselves, in a quasi-kaleidoscopic fashion. In view of all these combined wonders it is clear that not merely a volume, but many, would be requisite for even an attempt to give an exhaustive answer to the question, "What is a flower?" since it is seen to be a cosmos in itself when fully studied.

MR. P. RUDOLPH BARR.

Mr. P. Rudolph Barr, whose portrait we have the pleasure of giving in this issue, is well-known as the senior partner in the firm of Messrs. Barr and Sons, and by reason of his geniality and ability is held in high estimation in horticultural circles, and, indeed, by all who have the pleasure of being acquainted with him and his work. Although a comparatively young man, it is now many years since Mr. Barr assumed his present position, on the retirement of his father, the late Mr. Peter Barr, V.M.H., from business, and in looking back over the period that has elapsed, it is interesting to observe how fully the traditions of the firm have been maintained. It need not now be recounted that the late Mr. Peter Barr was the pioneer of the daffodil cult in this country, and that he was successful in introducing many noteworthy daffodils into cultivation; but it should be of interest to mention that his love for and interest in the daffodil was shared by his sons, and that, as the result of this love and interest, combined with rare judgment, the firm is as closely identified with daffodils, and as busily engaged in the creation and distribution of new varieties at the present time as at any period in its history. That Mr. P. R. Barr, in conjunction with his brothers, takes a close interest in daffodils as in other branches of the business, goes without saying, but apart from the commercial aspect of these delightful flowers he has devoted much personal attention to them, and has long been regarded, and deservedly so, as one of the leading authorities on them. His thorough acquaintance with varieties was shown in a marked manner by the splendid service he rendered in the classification of daffodils which was accomplished by the Royal Horticultural Society's Daffodil Committee, of which he is a member. Mr. P. R. Barr is the honorary auditor of the Royal Gardeners' Orphan Fund, and the high appreciation of his services by the members is made abundantly evident by the unanimity with which he is re-elected on the periodic expiration of his term of office.

St. James' Park.—We are pleased to say the project for the erection of a memorial to King Edward VII. in St. James' Park, has, in consequence of the strong opposition to which it gave rise, been abandoned by the Executive Committee of the memorial fund. No question has been raised in any quarter as to the erection of a memorial in every way worthy of the splendid services rendered the country by the late King, during his long and active life. The objection has been to the erection of the memorial in a position in St. James' Park where it would, in conjunction with the proposed architectural bridge over the ornamental water, greatly impair the rural charms for which the park has so long been famous. It is surprising that men of acknowledged ability should have failed to appreciate the fact that the erection of a stately memorial and a highly ornate bridge in a comparatively small open space remarkable for its rural features, would greatly impair its amenities. Happily public opinion has been strong enough to save the rural aspects of the park, and to show that keen interest is being taken in the open spaces that form so valuable a heritage of those who reside in or visit the Metropolis.

The Gardeners' Royal Benevolent Institution. We have much pleasure in announcing the fact that the Queen has sent £10 10s., and Queen Alexandra £25 in aid of the funds of The Gardeners' Royal Benevolent Institution, of which Their Majesties are patronesses.

New Director of the "Times" Experimental Station.—We learn that Mr. Silas Cole, for many years head gardener to Earl Spencer, at Althorp Park, Northampton, has been appointed to succeed the late Mr. Charles Foster in the management of the "Times" Experimental Station, at Sutton Green, near Guildford. Mr. S. Cole (whose portrait we published in our issue of February 18) is well known as an able cultivator, competitor, and administrator. He was the raiser of the famous waved Countess Spencer sweet pea that has revolutionised this popular flower, and has ever been a most successful vegetable grower, hence his appointment to SuttonGreen will be particularly pleasing to the members of the National Sweet Pea and National Vegetable Societies, both of which have trials in hand at the "Times" Experimental Station.

National Rose Society.—This society will have a busy day on Tuesday, April 25. At three o'clock a special general meeting will be held at the Westminster Palace Hotel to receive the report of the Council on the proposed revision of the rules and byelaws of the society, and to consider and deal with the same. At five o'clock a rose conference will be held at the same hotel, when the President, the Rev. J. H. Pemberton, will give an address on "Roses for the Garden," to be followed by a discussion. To this meeting members and their friends, including ladies, are invited, and will be admitted on presentation of their address cards. This in its turn will be followed by a dinner, also at the Westminster Palace Hotel, at seven o'clock. The Rev. J. H. Pemberton will preside, and all members and their friends, including ladies, are invited. Those who intend being present at the dinner must give notice to the honorary secretary on or before Thursday, April 20, that suitable arrangements may be made.

Aquatic Plants are of special interest in these days, owing to the spread of water gardening, therefore any information concerning "The Origin and Structure of Aquatic Flowering Plants," cannot fail to be interesting also. Upon this subject the Rev. Professor G. Henslow, V.M.H., will lecture at the Royal Horticultural Hall on Tuesday, April 11, at 3 o'clock.

Importation of Potatoes into Jersey.—The Board of Agriculture and Fisheries desire to inform potato growers and merchants in Scotland that the States of the Island of Jersey have adopted an Act authorising the importation of potatoes from certain districts in Scotland from the 25th ult. to May 31 inclusive, on the following conditions: (1) The potatoes imported must form the sole cargo on the vessel, and must come direct from the district where they were grown to be sent to Jersey direct from the port of landing. (2) Each cargo must be accompanied by a solemn declaration by the shipper, attested by a notary or commissioner of oaths, giving the place of origin of the potatoes and certifying that they have not been grown in land or soil affected by wart disease of potatoes. (3) Each cargo must also be accompanied by a certificate of the Board of Agriculture and Fisheries to the effect that the district in which the potatoes were grown is free from disease. Intending exporters of potatoes to Jersey should, when applying to the Board for a certificate, forward the declaration from the grower of the potatoes referred to above. The declaration should state the parish in which the potatoes were grown. The adoption of this Act is probably due to the need that is felt by potato growers in Jersey for a change of seed from the northern parts of the British Isles. As potato growing in Jersey is almost exclusively devoted to the early crops, it may be assumed that such varieties as those grown in the South-West of Scotland for early summer crops will find must favour in the Jersey markets.

The Brent Valley Bird Sanctuary, near Ealing, serves a very useful purpose, and lovers of bird life are loud in their praises of the successful efforts of the Selborne Society to retain an area of nineteen acres, near London, where birds may be preserved unmolested. It must be remembered, however, that this bird sanctuary, concerning which Mr. Wilfred Mark Webb, F.L.S., is to lecture before the Horticultural Club on Tuesday evening, April 11, occupies an unusually advantageous position. Towards the south and south-west there are the extensive open spaces provided by the Gunnersbury House, Gunnersbury Park, Osterley Park, and Syon Park estates, with Kew Gardens, Old Deer and Richmond Parks, and Wimbledon Common farther afield. The lecturer is the hon. sec. of the Selborne Society, and his lecture is sure to be of great interest.

Rhododendron Show at Vincent Square.—Messrs. John Waterer and Sons, Ltd., of Bagshot, Surrey, will this year hold a special exhibition of rhododendrons at the Royal Horticultural Hall, Westminster, from May 30 to June 3 inclusive. Messrs. Barr and Sons, Covent Garden, will at the same time exhibit bulbous and other hardy flowers. Fellows of the Royal Horticultural Society will be admitted free on showing their passes, but a charge for admission will be made to the general public.

An Addition to the Great Sweet Pea Prize.—We understand that Messrs. John K. King and Sons, of Coggeshall, Essex, are offering a massive gold cup, value £50, or other article of plate, to the winner of the £1,000 prize offered by the "Daily Mail," provided such winner has grown the flowers from seed supplied direct from Messrs. John K. King and Sons.

Weather in Glasgow, 1910.—We acknowledge with much pleasure the report by Mr. James Whitton on the climatic conditions that obtained in Glasgow during the year 1910. The report is, as usual, of much interest, for not only does Mr. Whitton give a full record of the rainfall and temperature, but makes a number of useful remarks upon the general effects of the weather upon vegetation. In summarising the report Mr. Whitton states that in comparing the records of 1910 with those of 1909, the remarkable feature of the weather conditions is their general similarity. This is specially notable in the case of the rainfall as regards the total. The same may be said as to the temperature, though the year under notice was more uniform and slightly better. There were, perhaps, less prolonged spells of easterly winds, but those in the spring months unduly retarded vegetation, and during the flowering period of trees and shrubs caused much damage to the tender growths, and, by injuring the blossom, ruined the prospects of a fruit crop. Generally speaking, the display of bloom was under the average on trees and shrubs. Pears, plums, and cherries were but moderately flowered, while apples were well bloomed; but none set fruit freely on account of the conditions above-mentioned and exhaustion through a lack of atmospheric moisture. The hard dry winds lacerated and browned the first leaves on chestnuts and acers in exposed places, and many were in a pitiable condition. Later-growing trees and shrubs fared better, and made a quite satisfactory growth, which has ripened well, consequently the prospects for the coming season are favourable. Rarely has the bulk of the rhododendrons been so full of flower buds, and promise a finer display than that of 1908, when the bloom on these splendid shrubs was notably good. Though the fog fiend was in evidence at times, its frequency and density was not so marked as that of the previous year, and so far as its effects on the trees and shrubs in the Glasgow parks, the damage was not so apparent.

Plant Distribution.—The other evening at Hull the Rev. J. R. Wynne-Edwards, president of the Leeds Philosophical Society, gave an interesting lecture on the "Local Distribution of English Plant Life." At the outset of his lecture Mr. Wynne-Edwards said it was very difficult to account for the reappearance of the present British flora after the glacial period. The fossiliferous rocks afforded abundant evidence of the existence of many of the kinds prior to that epoch, and with reference to their return with warmer conditions, the view was held that the plants of the temperate zone merely retreated before the arctic invasion, and returned when the climate became milder. This theory he regarded as untenable, because plants only flourished in soils that were suited to their requirements, and there did not exist in this country continuous areas of soil along which they could have retreated and advanced. Mr. Wynne-Edwards expressed the opinion that the solution of the problem was to be found in the many and varied methods of distribution with which seeds are gifted. The various methods of distribution were passed under review and briefly described, and much other information of interest given.

The Metropolitan Public Gardens Association.—This Association has just published its twenty-eighth annual report, and from it we gather that the very excellent work of adding to, reclaiming and beautifying open spaces in the great Metropolis continues, and that such work is only limited by the financial support forthcoming. During the year 1910 the Association has secured the preservation of portions of Hampstead Heath from enclosure, and acquired for the public use spaces at Paddington, Kilburn, Shadwell, and Richmond. After years of endeavour it has opened West Square, Southwark, as a public recreation ground, and laid it out as a beautiful garden. The sum of £1,072 11s. was expended on the purchase of grounds, laying out, and maintenance of grounds, tree planting, window-garden competitions, and public seats. The Association is in no sense jealous of the work done by other bodies in a similar direction, and it is pleasant to find in the "Report" a ready appreciation of the efforts of the local authorities in the County of Middlesex, who, since 1897, have acquired no fewer than 43 separate areas, amounting to 1,078 acres, for the public use, at a cost of £584,280. Ranging from the provision of seats for the weary, and the acquisition of open spaces, the Association has successfully carried out or assisted in no fewer than 593 good works since 1882, and it is therefore well worthy of support.

Transactions of the Scottish Horticultural Association.—Part 3 of the first volume of the new series of these "Transactions" is before us, and, apart from the statistical and other matters of more or less local interest, it is a generally useful publication, and well worth the shilling charged to non-members. Mr. Matthew Todd's "Retrospect" shows how the Association came into being, while "The Rise and Progress of Gardening from the Earliest Period to the Present Time," is a wide subject, dealt with pleasantly by Mr. James Grieve. "The Working of Garden Soils," by Mr. James Whytock, of Dalkeith, and "The Working and Management of Garden Soils," by Mr. G. P. Berry, of the Edinburgh and East of Scotland Horticultural College, are practical subjects of the first importance, and deep cultivation is the text in each case. "Weather Forecasts," by Mr. James Moncur, "Sense Organs of Plants," by Dr. W. E. Smith; "Insect Pests," by Mr. George E. Greenhow; "Flower Gardening;" by Mr. D. W. Thomson; "The Cultivation of Peaches and Nectarines under Glass," by Mr. Thomas MacPhail; "The Perpetual Flowering Carnation," by Mr. J. S. Brunton; and "Plant Diseases," by Dr. A. W. Borthwick, are the other papers contributed, all of which have been read before the Association at its monthly meetings.

Legacy to a well-known Northern Gardener.—By the terms of the will of the late Lord Airedale, which was published March 29, Mr. Wm. Grix, the Gardens, Gledow Hall, Leeds, will benefit to the extent of his lordship's bequest of £250. One year's wages is also bequeathed to all indoor and outside servants who have fulfilled two years' service. Mr. Grix is a highly respected gardener of well-known ability.

The Aberdeen Botanical Gardens.—Much interest is at present being taken in Old Aberdeen in the work being carried on in connection with the extension of the Botanical Gardens. The ground forming part of the existing gardens is held on a lease from year to year under conditions that are unsatisfactory, and some time ago, when a piece of adjoining land came on the market, it was bought for the Botanical Gardens. The ground is about three acres in extent, and is well suited for the purpose of a botanical landscape garden, the soil being of good quality, with a slightly undulating surface sloping to the south. A large dwelling-house, forming part of the estate, has been completely renovated, and about a quarter of an acre at the back has been cleared of trees, surrounded by a wall, and laid out as a lawn-tennis court and garden, with flower borders, etc. A number of other trees have lately been cut down, a row being left along the outside of the dyke. Some of the trees on the north side of the property have likewise been felled, and it is understood the intention is to remove a number of the smaller and stunted trees on the west side, where at present there is a narrow belt running from top to bottom. All these have been a very pleasing characteristic of this part of the town, and there is a feeling prevalent that by their removal the landscape is being robbed of one of its most charming features, and that trees which contribute so much to the delightful aspect of Old Aberdeen should be preserved. It is urged that richly-foliaged, overhanging trees have a destructive effect on vegetation underneath, and also that as the trees are ash, elm, beech, and plane it would be better to have a greater number of species.

SOME OF THE FINELY-DEVELOPED GOLD MEDAL AMARYLLIS.
Exhibited by Messrs. R. P. Ker and Sons at the Liverpool Show, April 5 and 6.

SINGLE DAHLIAS.

Foremost among the various candidates at the present time for popular favour as autumn flowers must be placed the single dahlias, which, at that season, make the most brilliant display in the garden of them all. The single dahlia is, moreover, the ancestor of all the other types of dahlia, and the easiest to grow. Indeed, its cultural requirements are of the simplest character, and only three in number—planting, staking, and the frequent removal of the blooms as they fade.

Planting.

The young plants or divided tubers, as the case may be, should be planted out as soon as all fear of frost is at an end, say early in June. Five feet between the plants each way is not too much to allow them if they are intended for a bed, and this is by far the best way of growing them in order to obtain an effective display of bloom.

Staking.

A single firm stake will be sufficient to tie the new growths to at first, but when the plants become established four stakes should be driven firmly into the ground at equal distance round each dahlia—the stakes being connected by two rows of stout but soft twine, so that the shoots may be held up without destroying the natural appearance of the plants. The stakes when in position should not be more than about four feet out of the ground.

Removing Faded Blooms.

The only other attention needed, and it is perhaps the most important of them all, is the removal of the blooms as they fade. The reason for this is that the flowers are so numerous and follow each other in such rapid succession, that if allowed to form seed pods, such a strain would be put on the plants for the perfecting of the seeds that the plants, if left entirely alone, would cease to produce fresh flowers, whereas if the faded blooms be cut off once, or, better still, twice a week, the plants will remain in full flower until cut down by frost.

Selecting Varieties.

There is one most important caution for the beginner, and that is never to raise the plants from seed, however good seed may be, but always obtain named varieties from the nurseries. The latter are inexpensive, and, as they have been selected from hundreds, if not thousands of seedlings, are certain to give satisfaction, whereas if raised from seed, the colours being unknown, there will be no means of arranging the plants satisfactorily in a bed, and a very large majority of them would be but poor representatives of what a modern single dahlia should be.

I append a list of the varieties selected, at all events of all those of which I can find the colours, at a recent trial of single dahlias, as the best and freest-flowering varieties in cultivation in their different colours, viz.: Snowdrop, white; Peggy, rosy-crimson tipped orange; Leslie Seale, lilac with crimson centre; Columbine, pale rose; Lady Bountiful, mauve with crimson centre; Miss Roberts, yellow; Kitty, rosy-mauve with dark centre; Owen Thomas, crimson, tipped yellow; Amy, terra-cotta; Vesuvius, orange-scarlet; Rosebank Scarlet, scarlet-crimson; Miss Morland, crimson-scarlet; Fugi San, orange-yellow with crimson centre; Winona, deep maroon; and Morning Glow, amber with scarlet centre.

Edward Mawley.

SWEET PEA JOTTINGS.

The temptation to plant out sweet peas on Saturday, April 1, was very great, but other work was pressing, and so the temptation was resisted. During that evening, and the whole of April 2, the rain fell steadily, and the wind, though not strong, came from the north-east, followed all day on Monday, April 3 by a biting north wind, that found its way even through one's winter greatcoat. I was glad I did not plant out, for the plants were quite happy under a covering of fish netting, and with the pots plunged to the rim in ashes. In one or two cases there is an occasional bleached leaf, but every seedling is making vigorous growth from the base.

I imagine that some thousands of pot-raised sweet peas will be planted out during Eastertide this year, and, weather permitting, this will be a very good time for the work. Sifted decayed material from an old rubbish heap added to sifted ashes from the garden fire makes good stuff to use at planting time, mixing it freely with the staple soil in the shallow trench, and pressing it firmly about the sweet pea roots. Firm soil is a great factor in successful sweet pea culture, and where the ground has been trenched during the winter it is a matter of first importance that it be made firm by treading in both directions before the plot is raked down and marked out for planting.

The popularity of the sweet pea is responsible for several interesting movements. In more than one place sweet pea exhibitions are being promoted for the purpose of raising money for sick nursing funds and for hospitals. The latest thing of this kind that has come under my notice is the promotion of a sweet pea exhibition for the purpose of raising funds for a golf club. Sweet are the uses of—sweet peas.

The "Daily Mail" £1,000 prize for a bunch of sweet peas has caused a good deal of heart-burning, especially since a regulation was formulated that renders ineligible everyone who has won a first prize at a show of the National Sweet Pea Society. Those who would be otherwise eligible feel they are being penalised; others who are still eligible are so keen on winning this little fortune that they will not compete at the N.S.P.S. show on July 11, lest they should win a first prize, and thus render themselves ineligible for the other competition.

Messrs. J. K. King and Sons, Coggeshall, are offering a £50 gold cup to the winner of the thousand pound prize, but the condition is that the winning flowers must have been grown from seeds supplied by Messrs. J. K. King and Sons. It seems to me that the offer has come too late to be of real service to any of us. Supposing several firms made a somewhat similar offer, and the winning bunch of twelve spikes contained six varieties, two sprays of each, and that each variety was obtained from a different seedsman, all of whom were offering a special additional award on the above lines, would the winner receive all these special awards, or none of them, or a sixth part of the value of each?

So far as the sweet pea trials are concerned it seems to be quite in accordance with the general fitness of things that Mr. Silas Cole, the raiser of Countess Spencer, should follow the late lamented Charles Foster in the directorship of the "Times" Experimental Station. Mr. S. Cole is well known as a skilful grower, and in his charge of the gardens at Althorp Park he has had opportunity for the display of organising ability. He has to follow a man of remarkable personality and exceptional qualifications, but he should prove a worthy successor.

The membership of the N.S.P.S. grows steadily, and probably by the time these notes appear two hundred new members will have been enrolled this year. The number of societies in affiliation also increases. Among recent additions are two quite new societies, one at Strathpeffer and one at Whitchurch. The latter, with the Rev. J. Jacob as its president, and with Mr. Eckford, Mr. T. Jones, and Dr. Phillips all quite handy, ought to prove a great success. Mr. Jacob told me the other day that fifty members were enrolled at Whitchurch in a week.

Charles H. Curtis.

NEW PLANTS, ETC.

ODONTIODA VUYLSTEKEÆ VAR. LADY COLMAN.

A particularly fine form of this beautiful bigeneric hybrid, and one in which the whole flower is a deep, rich, and brilliant scarlet shade. F.C.C., R.H.S., March 28. Sir Jeremiah Colman, Bart. (gardener, Mr. Collier), Gatton Park, Reigate.

ODONTOGLOSSUM SWIETENI-COLOR.

A large-flowered and striking hybrid from O. Wilckeanum and O. Vuylstekei. The blooms are big, but not of the best form; the colour is rich mahogany-red (the Swietenia is the Mahogany tree), margined with cream yellow. A.M., R.H.S., March 28. Sir Trevor Lawrence, Bart. (grower, Mr. W. H. White), Burford Lodge, Dorking.

ODONTIODA IGNEA.

This is an entirely new hybrid derived from Cochlioda Noetzliana and Odontoglossum Lindeni. The flowers are small, and suggest the last-named parent in form, but they are of a deep red-scarlet hue, and borne freely in a branched inflorescence. A.M., R.H.S., March 28. Messrs. Sander and Sons, St. Albans.

CARNATION EMPIRE DAY.

This is a most delightful perpetual carnation, the shade of pink colour it shows being exquisite. It is free flowering, and has many good qualities besides its charming colour to recommend it. A.M., R.H.S., March 28. Mr. A. Smith, Enfield.

RHODODENDRON MRS. KINGSMILL.

A fine hybrid rhododendron bearing its bold white flowers in large trusses. The parents are R. Aucklandi and R. campylocarpum. It is early flowering, opening in March out of doors in the south. A.M., R.H.S., March 28; Miss C. Mangles, Littleworth Cross, Seale, Farnham, Surrey.

XERONEMA MOORI.

This striking liliaceous plant comes from New Caledonia, and was introduced about 1875. In habit the plant somewhat resembles an iris. The scape is a foot or more long, bearing a raceme that is bent almost at right angles to the scape. The small, numerous flowers are erect, rich red, with long purplish-red stamens. At Kew the plant succeeds under the treatment usually meted out to South African bulbs, and it flowers annually in June. "Bot. Mag.," t. 8,343.

PLEIOCARPA MUTICA.

A beautiful stove plant that needs similar treatment to the ixoras. It is a native of the Camaroons and Old Calabar. The plant is shrubby, and the white, shortly pedicelled flowers are borne in rounded clusters from the axils of the leaves. "Bot. Mag.," t. 8,344.

COLUMNEA OERSTEDIANA.

A native of Costa Rica, this showy plant has much the general appearance of an Æschynanthus, and it is an epiphytic shrub requiring similar treatment. The erect flowers are three inches long, borne singly in the leaf axils; the mouth of the flower is bi-labiate, and the colour is light scarlet. "Bot. Mag," t. 8,344.

PYRACANTHA ANGUSTIFOLIA.

Discovered by Delavay in Yunnan in 1882, this thorn was first described as a cotoneaster. It is a shrubby species, but at Kew is not fully hardy in the open, but at Torquay it flourishes and flowers and fruits freely. The flowers are white, and the berries orange-yellow. "Bot. Mag.," t. 8,345.

LEVELLING GROUND.

There are few operations in connection with the formation of gardens, croquet, tennis, bowling, and others lawns and greens, that require more knowledge, care, and experience than the levelling of ground. Yet, although this is the case, it is not by any means a rare thing to find a builder's contractor making terraces in front of the house he has erected, and shaping and levelling the other portions of the ground attached. His knowledge of soils usually amounts to being able to tell which will make bricks, and which are suitable for mixing with lime in the preparation of mortar. The surface soil, the rich storehouse of plant food, has no virtue in his eye, and no special adaptability for any purpose, consequently, it not infrequently, in the process of levelling, is buried below a layer of crude clay or barren gravel.

When it is remembered that this surface layer of soil has taken ages to bring it into its present condition of suitability for plant growth, and that the stratum upon which it rests is generally crude, and barren of plant food, every care should be taken, when levelling operations are in progress to preserve every ounce of the surface layer. To do this some remark that the cost is too great, as the other method of accomplishing it with which they are familiar is that of wheeling all the good soil off the piece to be dealt with, levelling the subsoil, and then returning the top layer to the surface. A much more economical way of accomplishing the same results is that of levelling the ground in sections. This reduces the wheeling and handling of the soil to a minimum.

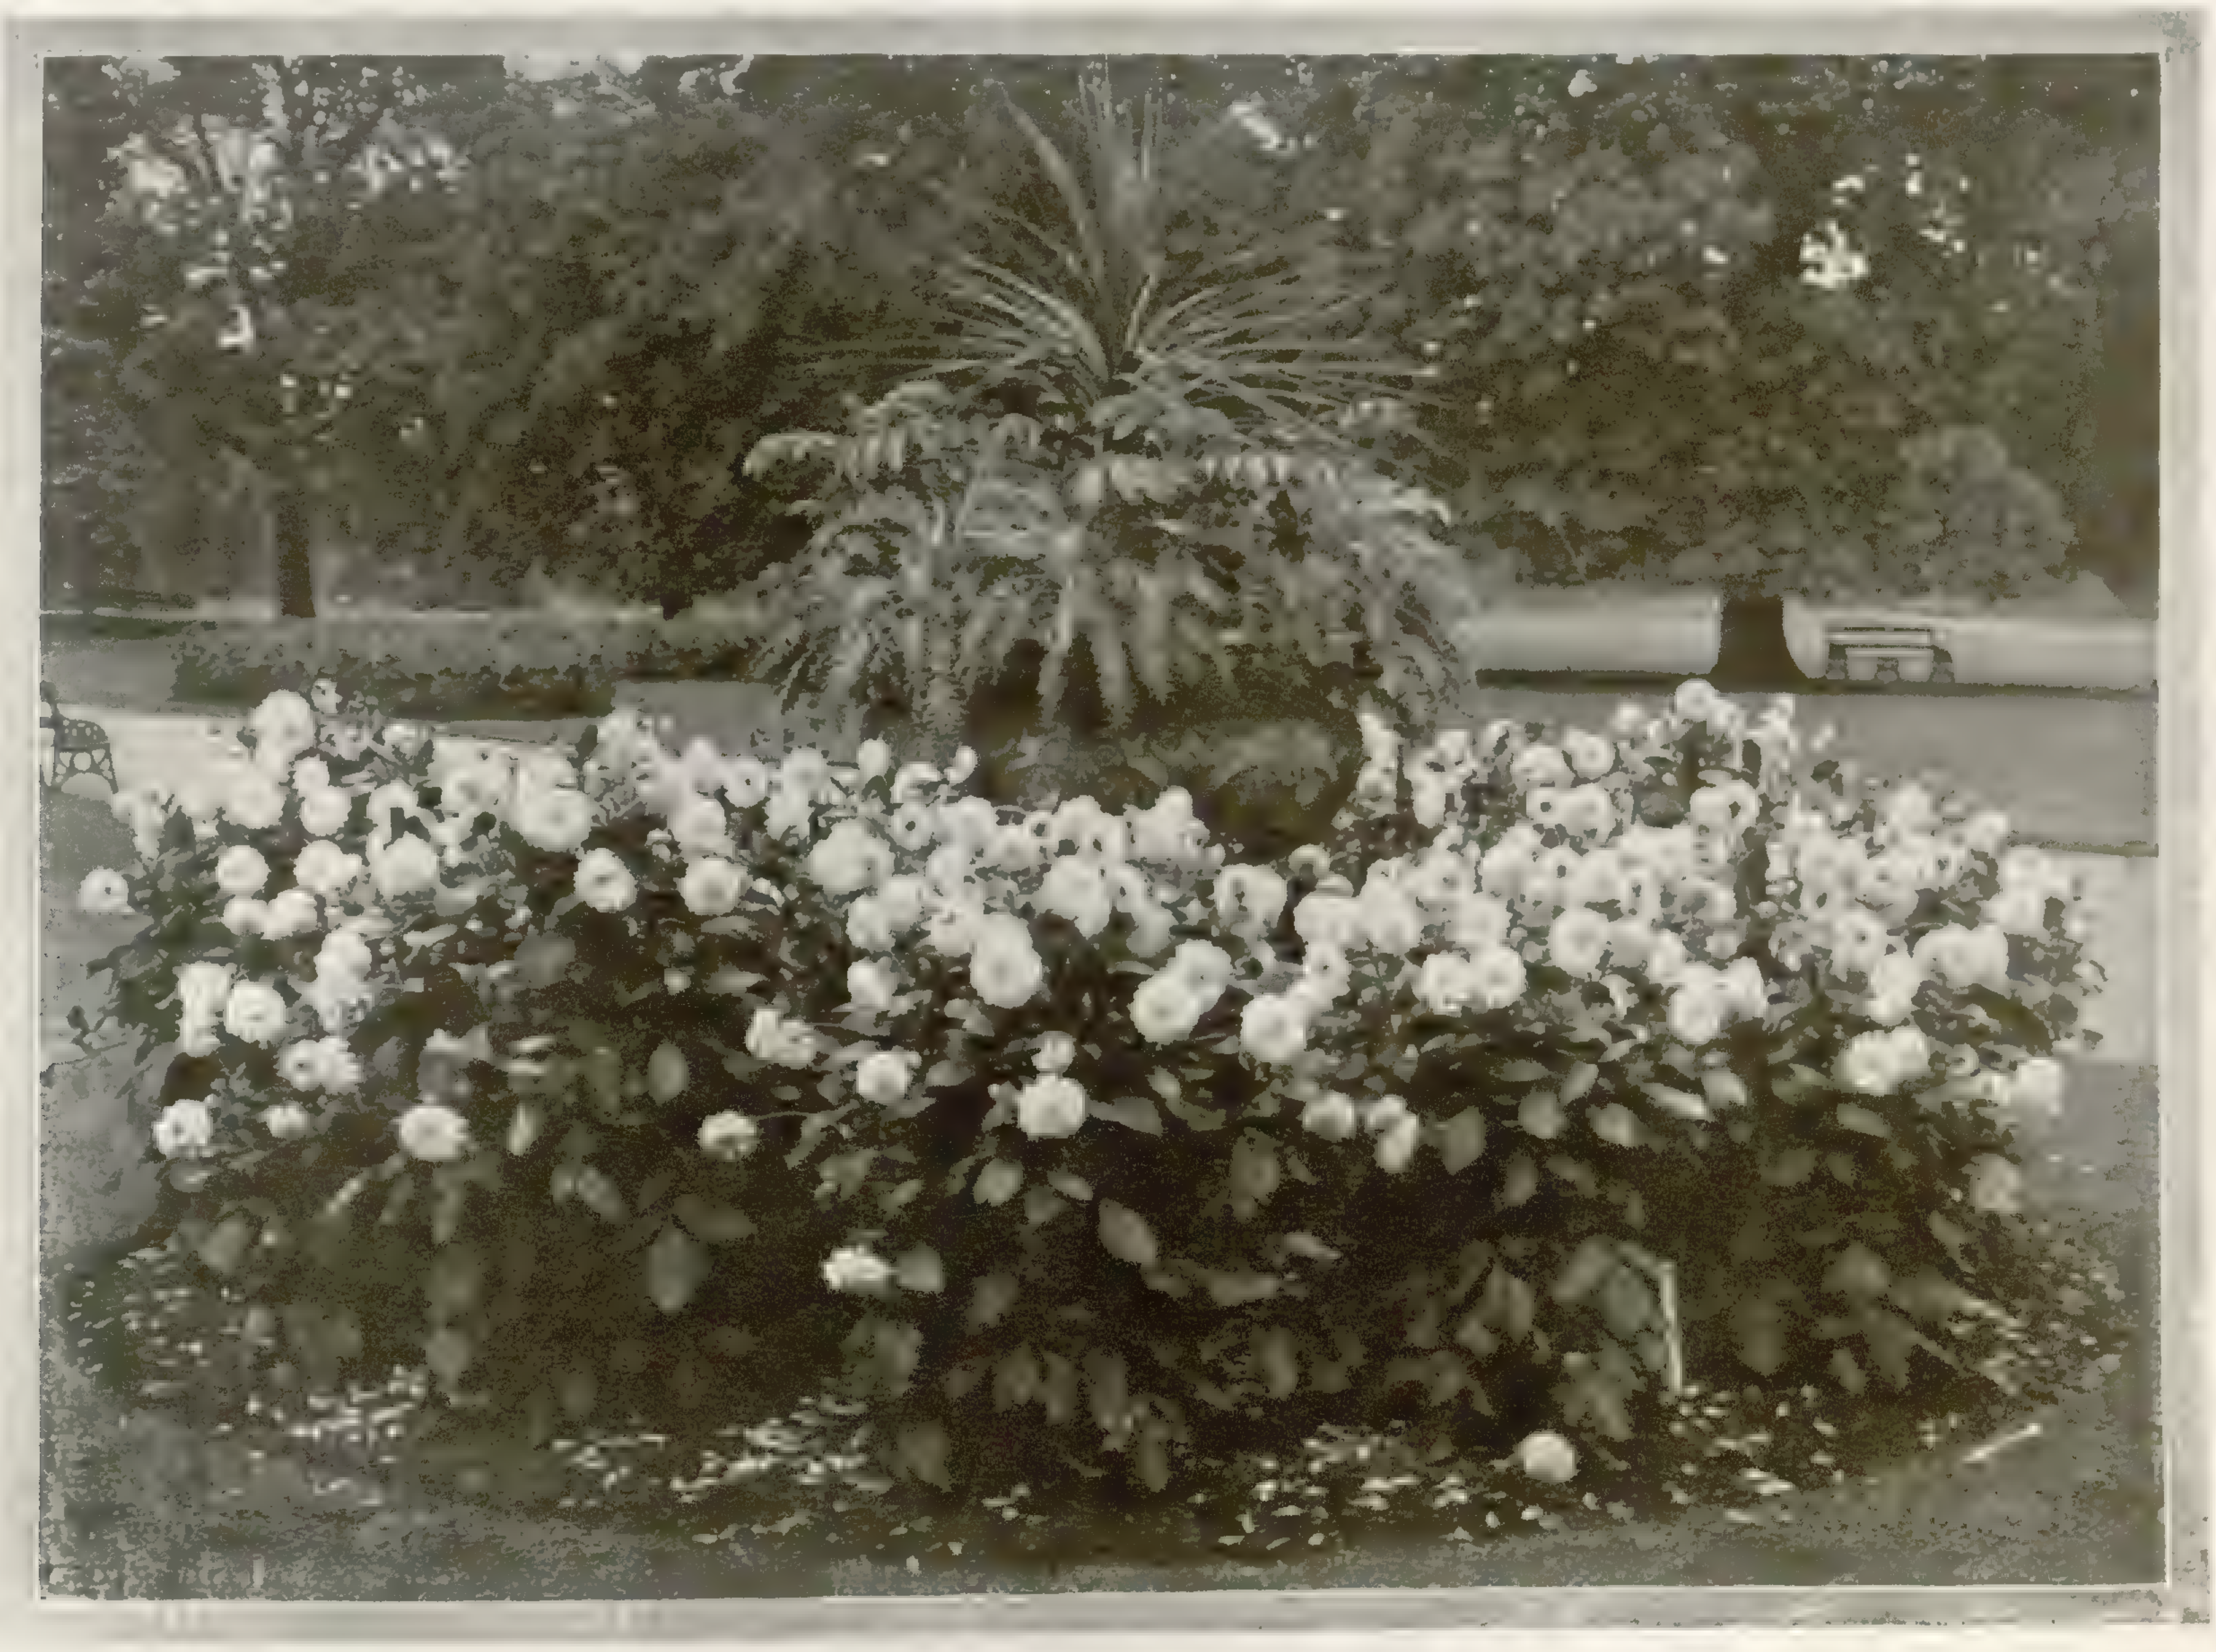
This system of levelling is effected by taking out an opening eight feet wide and nine inches deep along one side, and wheeling it to the one opposite. If there is a corner lower than another on the ground this opening should run from it to the higher side. This done, an opening eight feet wide and the same depth as the other should be taken out along the highest side, but in this case the soil should be ridged along the side of it. With the average level fixed, the subsoil can be wheeled from the higher ground to the lower till a level nine inches below what is to be the surface is secured, then the surface soil, eight feet wide, from the adjoining piece of ground, used to finish off the first section. The second section can then be treated in the same way, and so on, section after section, till the whole has been levelled. The object in taking out the opening along the higher end, or side, is to afford necessary material for levelling. This method of levelling is very much after the style of trenching, only the opening is wider. Although eight feet is given as the width of the sections, yet where there is little fall in the ground much narrower widths can be employed.

Should the object be to secure a surface of turf the filled up portion should be made solid from the foundation by treading with the heel. The roller does not find the soft parts, but once the ground has been made firm and finished it is useful for breaking up any lumps, and aiding in bringing the surface soil into a fine tilth for either seed or turf. In levelling for kitchen garden purposes it is advisable to have a depth of not less than two feet of good soil, so that, in this case, the opening should be made as deep as the desirable surface soil goes, if it is under two feet. In all levelling operations the aim should be to accomplish the work in the easiest and most economical manner, and to retain the surface soil on the top. Hibernia.

DAHLIA KAISERIN AUGUSTA VICTORIA.

During the last few years much more attention has been paid than formerly to the decorative value of the dahlia in the garden, and were I so unfortunate as to be restricted to growing only one variety, without hesitation the subject of this note would be my choice. It is a variety for dahlia lovers of every class, from the owner of a castle, around which he can cause it to be planted in hundreds, to the small town or suburban garden, where space can only be found for one or two plants in the border. It is perhaps best described as a double decorative bedding variety. The flowers are moderate in size, borne on stiff stems, every bloom being carried well above the foliage. The plants are free in growth, and particularly floriferous, seldom exceedingly a height of 3½ feet. The flowers are valuable for cutting, and, being white, are especially useful for wreaths and crosses. The variety is of German origin, and in Germany it is grown extensively during the winter under glass, when cut flowers are in demand. At Hampton Court and Kew it is one of the most popular bedding varieties. It must not be confused with the paeony-flowered variety bearing a similar name, of recent introduction, and with pale yellow flowers.

A. O.

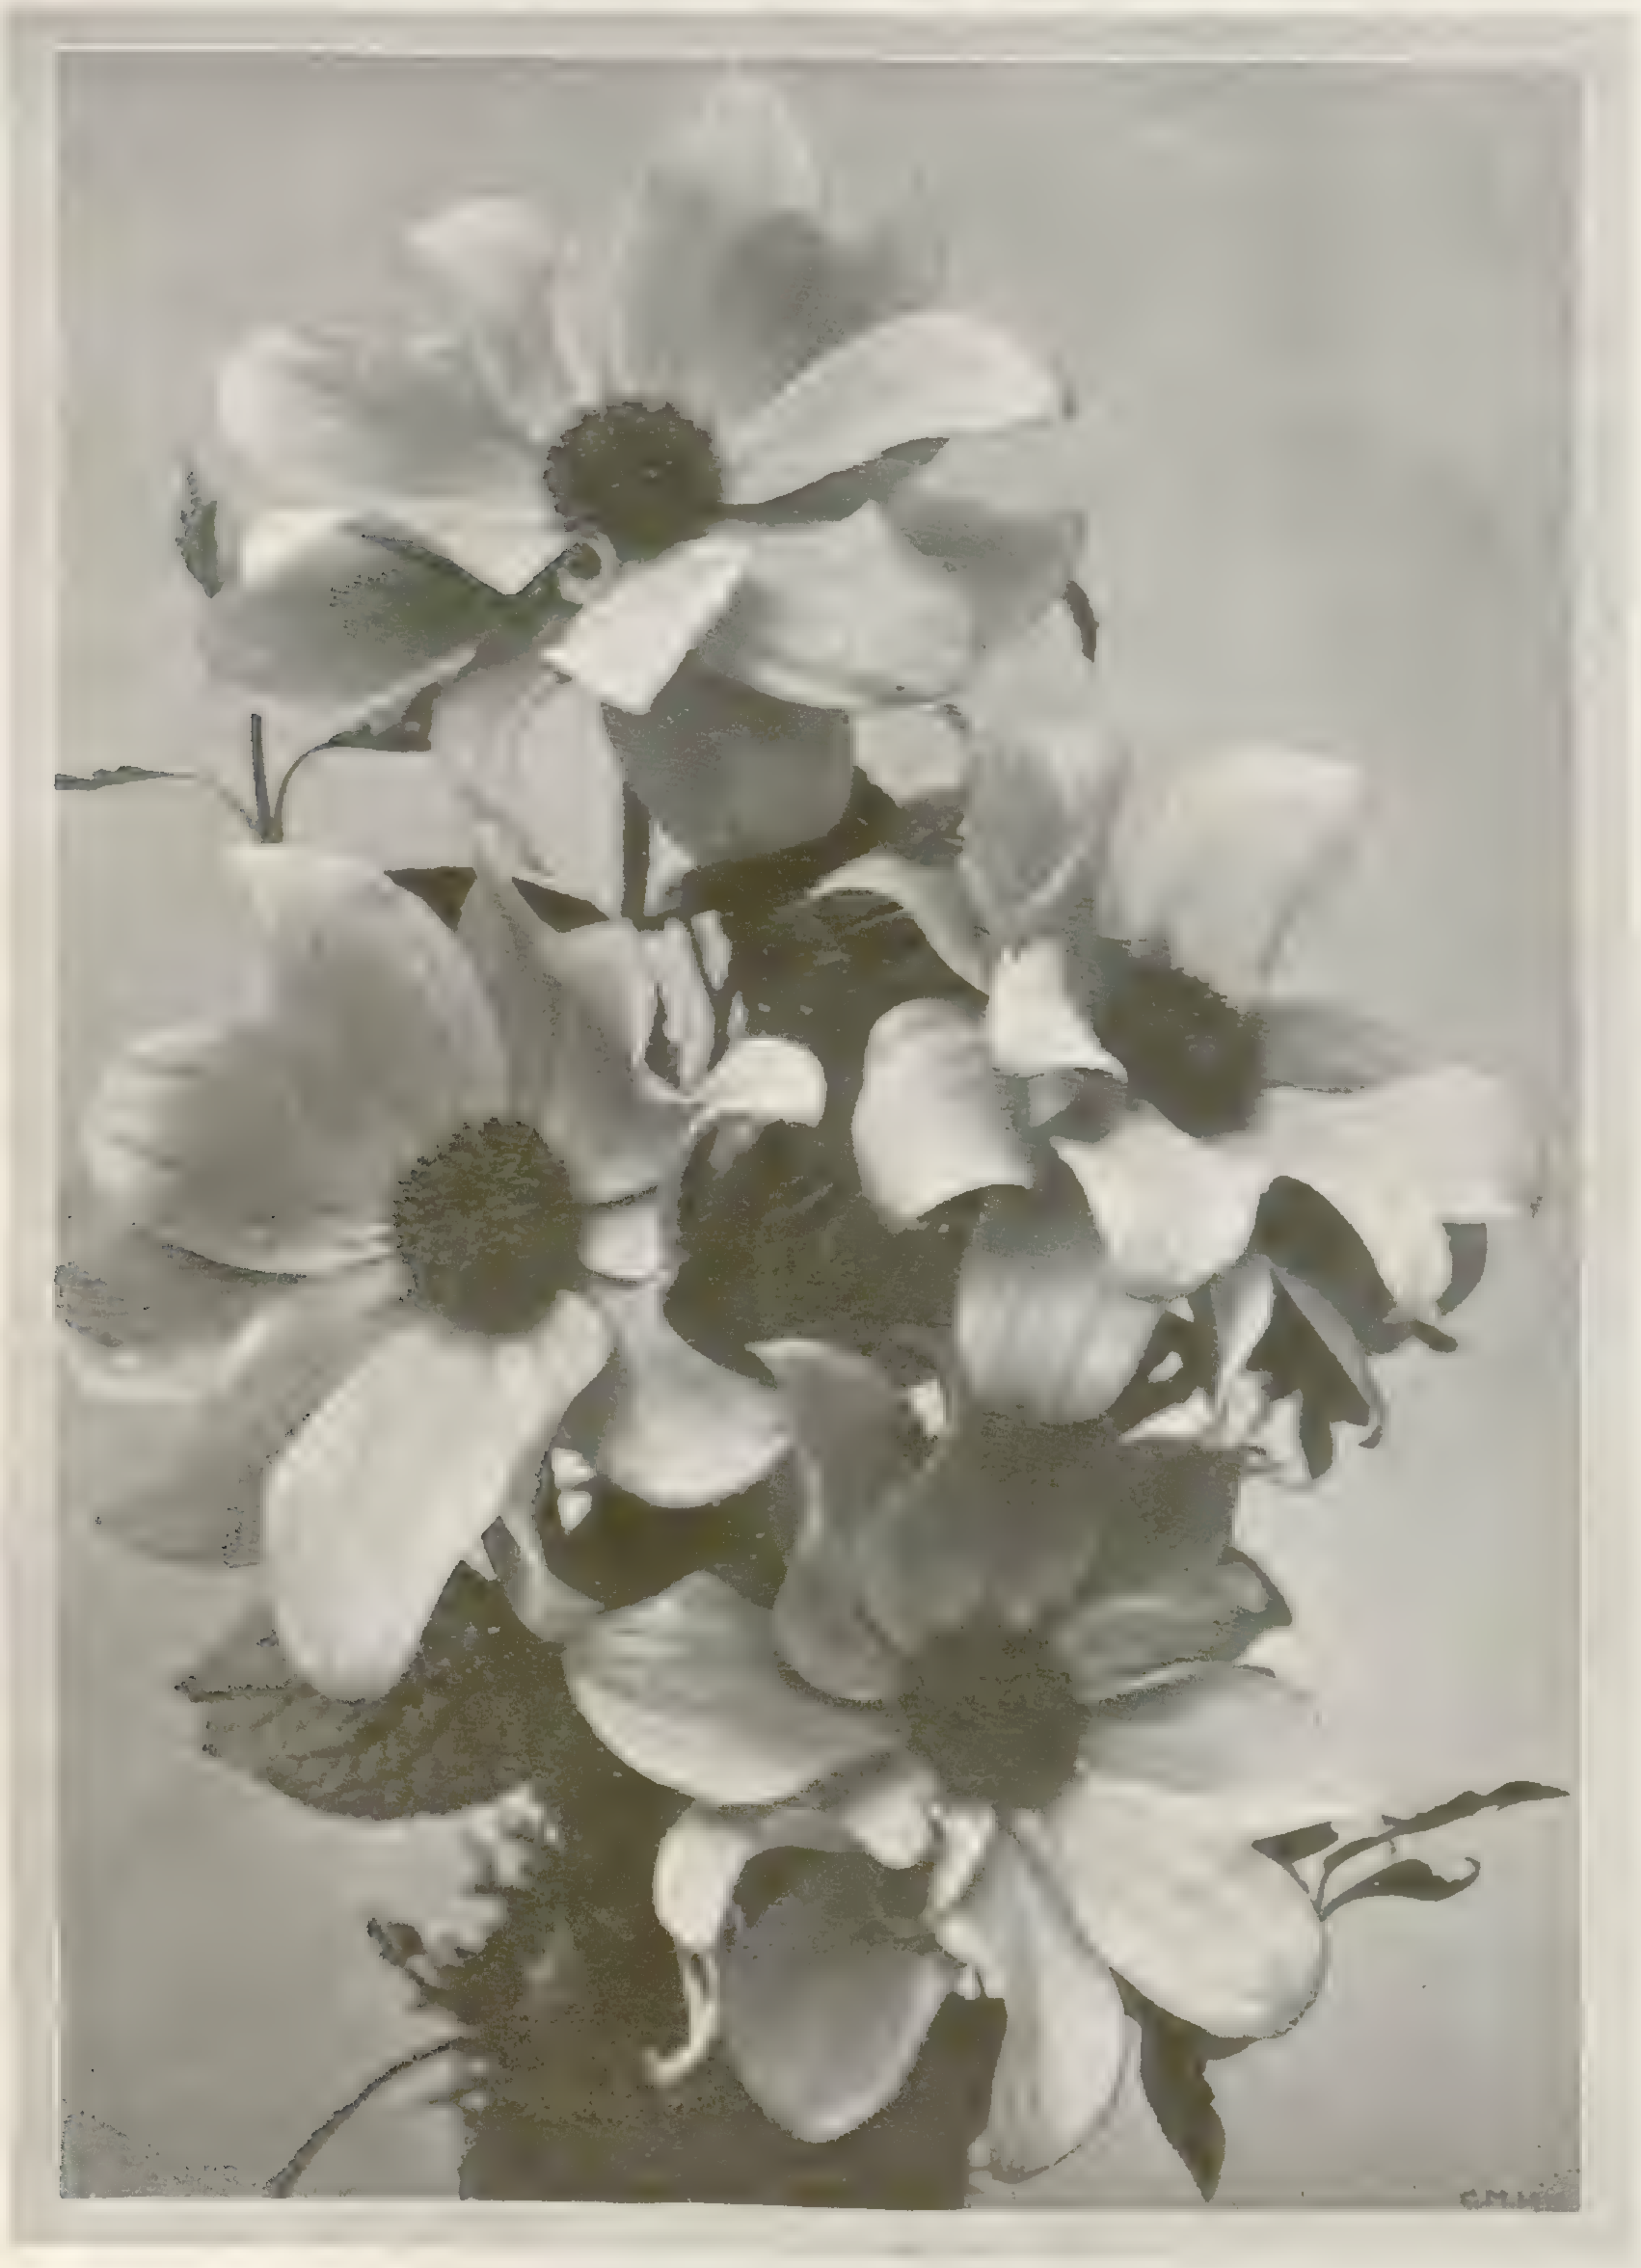


A FINE BED OF DAHLIA KAISERIN AUGUSTA VICTORIA AT KEW.
A very free-flowering white decorative variety.

Abutilon megapotamicum variegatum.—This very pretty free-flowering abutilon can be put to a variety of uses. In the first place, if grown as a loose, bushy specimen with the main branches looped up to a central stake, it forms, when in flower, a very attractive feature in the greenhouse; while even without blossoms it is decidedly ornamental.—W. T.

PÆONY-FLOWERED DAHLIAS

When first exhibited in this country, some six years ago, a good many by no means complimentary remarks were made about the pæony-flowered, or semi-double dahlias. The first recollections I have of their appearance in this country was at an exhibition of the London Dahlia Union, held at Earl's Court in the autumn of the year 1905. Several English growers were quick to recognise the possibilities of the flowers, and set to work raising new and improved varieties. That the pæony-flowered dahlia would so speedily rise in popular favour could scarcely have been imagined.



PÆONY-FLOWERED DAHLIA OLIVIA.

A distinct and beautiful single variety, raised by Mr. Charles Turner, the colours orange and fawn, suffused purple-rose.

The show, fancy, single, and cactus varieties each in their turn have held sway in the public favour, and the general favourites of the last ten years, the cactus section, are now seriously challenged by the subjects of this note. One can only guess at their origin; to me the flowers suggest a cross between the giant-flowered decorative class represented by Souvenir de Gustave Douzon or Jeanne Charmet, and the large-flowered single varieties. Until quite recent years raisers of new varieties in this country have invariably judged their seedlings from the florists' standpoint, their value in the garden and for cutting being more or less a secondary consideration. Numbers of these seedlings with flowers very similar in character to those first exhibited by the Dutch firm were discarded as useless. I remember the late Mr. Richard Dean saying a word for these semi-double seedlings, and they were promptly christened "Dean's mongrels."

The florists' ideal dahlias, however, are not exactly what the great majority of flower lovers require at the present day. Something bright and showy, easy to grow, and with flowers produced in profusion, is the demand of to-day, and this we have in the pæony-flowered dahlias. Vigorous growth, abundance of flowers, borne well above the foliage on stiff stalks eighteen to twenty inches in length, and bright colours, are qualities to recommend them for garden decoration. They are of particular value for massing in the pleasure grounds, to plant in large beds in the flower garden, and for the shrubbery border.

Always a popular flower for cutting, the demand for dahlias is increasing, while the last few years has seen a rapid change in the varieties grown for this purpose. For large displays or vases the blooms of the pæony-flowered section are ideal, having long stiff stems and good lasting qualities. A great fault with dahlias is the shortness of the flowering season. Given identical treatment with the other varieties we find the pæony-flowered section generally the first to bloom. In addition to the usual methods of propagation by cuttings, and the division of the tubers, the pæony-flowered section come fairly true from seeds, fully 50 per cent. having characteristic semi-double flowers.

The English-raised varieties already comprise a lengthy list, amongst which the following will be found a useful and varied selection: Codsall Gem, primrose edge, deeper colour in the centre, free and distinct. Hyde Park Gem, one of last season's novelties, sulphur-yellow. Lady Muriel Paget, a pleasing pure white, which attracted considerable attention at one of the fortnightly shows of the Royal Horticultural Society last summer. Lady Norman, a mixture of rose and apricot, distinct and pleasing. Mrs. E. Cragg, when opening the flowers are tinged with pink, changing with age to white, notable for the width and substance of the petals. Mrs. R. Copeland, a lovely rich pink, a shade of colour attracting immediate attention. Mrs. Ralph Heaton, a beautiful light rose-coloured variety, which is very effective. Mrs. W. E. Whineray, a very large flower, yellow centre, remainder of flower rosy-lilac. Ryton Roy.—This is a very rich yellow, of a golden hue. Romolo Piazzani, a most distinct colour, rather difficult to describe; it seems to be a mixture of orange, yellow, salmon, and red. Red Indian, a rich blood-red, the best of its colour amongst the English-raised varieties. Viscountess Newport, orange-red, free and good.

A selection of the best varieties should include the following sorts of Continental origin: Baron G. de Grancy, creamy-white, free flowering, blooms on good stems well above the foliage. Dr. K. W. van Gorkom, white, shaded rose, a pleasing flower. Duke Henry, the first dark red variety introduced, and still one of the best. Geisha, a pleasing orange-red shade with yellow centre, petals loosely arranged, a novelty of the year 1907. Germania, crimson-scarlet, shaded with yellow, very floriferous. Glory of Baarn, delicate pink, a typical semi-double flower of good substance. Hugo de Vries, orange, shaded bronze, not so tall in growth as most of the varieties. King Leopold, cream-yellow, the tallest grower I have seen, seven feet in height, flowers borne on long stems in great profusion. Paul Kruger, rosy-red and white striped, a very distinct flower. Queen Emma, salmon, flushed with lilac, one of the first varieties introduced. Queen Wilhelmina, a pure white variety of the first water, plants a mass of blossoms. Sneeuwwitje, in this country might be well named "Snow White," a larger flower than the preceding variety, and stronger in growth; there is room for both sorts.

A. Osborn.

Magnolia Soulangeana nigra.—Of all the early-flowering magnolias, that is to say, those which produce their blossoms before the advent of the leaves, this is the deepest tinted. On this account it will be at once singled out when in flower, for though the blossoms are wanting in the massive character of M. Lennei, and the purple tinge is less bright, its depth of colouring (well expressed by the varietal name of nigra) causes this variety to stand out distinct from all.—W. T.

NEW EXHIBITION CACTUS DAHLIAS.

Very much has been said and written about the modern exhibition cactus dahlia during the past few seasons. It has come in for much adverse comment from people who have attempted to grow it as a garden decorative subject and have been very disappointed with the result. But not so the exhibitor, who cares nothing whatever about the appearance of the plants as long as they produce magnificent flowers for the show boards. He is quite satisfied with the present-day plant, because it produces the type of flower the judges have been asking for in recent times, and there is no ignoring the fact that the incurving, claw-like floret has ousted all other forms from the show boards. How long this state of affairs will exist it is difficult to say, for we have to acknowledge the fact that the varieties seen at our shows are those demanded by the public, whether they are useful to them or otherwise.

In reviewing the varieties that were seen for the first time last season it is difficult to pass a definite opinion as to their merits, for every season does not suit certain sorts, and those that were in excellent form last year in a dull sunless season may not prove so satisfactory in a hot, dry year. I do not think novelties were quite so numerous as usual, though there were enough and to spare, goodness knows. Neither can one recall anything very sensational, though it must be admitted most of them were well up to the average for quality. Perhaps the most striking variety was Onward, which, except for the colour, resembled a fine head of endive, the colour being a soft pink; it will no doubt become a popular exhibition variety. Kingfisher must not be confounded with the older variety of the same name, for it is distinct both in form and colour. It is a fine exhibition form, with beautifully light florets of a deep rosy-mauve colour. The Earl, a rich ruby-crimson, with very incurving florets and a fine centre. New York, a superb variety, large enough to suit the most fastidious in this respect, while there is plenty of substance in the petals; the colour, too, is most pleasing, being orange-yellow in the centre shading to buff-salmon. H. L. Brousson, a very striking variety, with a colour all its own, difficult to describe, but its general appearance is deep rich rose, while the florets resemble spider's legs, they are so fine; the flowers appeared rather fragile, but the raiser assured me it was not so, and its unique appearance will make it popular. Golden Eagle, another variety that received the hall-mark of the National Dahlia Society, should be frequently seen, for though its description is yellow, overlaid fawn and pink, it is quite distinct from the numerous varieties so described.

Mention should be made of Dr. Roy Appleton, for it is one of those varieties with long straight petals that generally denote a good stiff stem, but it is deeper in build than most of this particular type. The colour is best described as yellow, shaded salmon.

All the foregoing varieties are to be distributed by Messrs. James Stredwick and Son.

Theresa.—This is best described as white flushed heavily with rose. The petals are of good form, while the flower has a good high centre. The only novelty in this section to be introduced by Mr. C. Turner, Slough.

Excelsior.—A very refined variety, with long and very narrow petals, with a perfect filbert centre, deep maroon in colour, I expect to make a name for itself, for it will prove a good reliable exhibition variety.

Primrose Queen.—The name describes the colour exactly, but it does not give any idea of the great depth of the flower, or its distinct formation, but beyond a doubt it is a coming variety. Pride of Essex, a full deep flower, rather short in the floret, a pleasing shade of yellow changing to amber on the outer florets, but will make a distinct exhibition flower. These emanate from Mr. J. T. West.

Mrs. Douglas Fleming is a valuable addition to the white varieties, and I venture to say will take its place with the best of the exhibition forms. It is a full, deep flower, with long elegant petals, creamy-white in the centre.

CACTUS DAHLIA WHITE ENSIGN.
A dwarf-growing white-flowered garden cactus variety, raised by Messrs. J. Stredwick and Son.

Mrs. Landale.—A very beautiful cactus variety of good form and depth, with excellent florets. The colour is best described as yellow ground edged with bright rose, a remarkably free-flowering variety. I noted it at Crawley last September as being one of the most attractive on the field.

Victory.—A cactus variety of the largest type, in fact its size alone arrests attention, while its colouring is most pleasing, being a rich coral pink. Both these varieties are from the new sorts being sent out by Messrs. J. Cheal and Sons, Crawley.

No doubt I have passed over several really good exhibition cactus varieties, but I have recorded those that I have noted during the past autumn as being the best in my opinion, and, as we are always liable to make mistakes, I regard first impressions as being most reliable from a florist's point of view. Other varieties of the same year will doubtless prove good and useful, but they did not impress me, as staged at the leading exhibitions last autumn.

J. B. Riding.

VIOLETS.

These flowers will now demand attention with regard to propagation for providing a stock for the autumn planting in frames. The side growths, or runners, always make the best plants, and these may usually be secured with a few roots attached when the old plants are lifted. These side shoots may also be taken as cuttings and rooted in boxes, but the former is the simpler plan. A piece of ground should be well prepared by giving it a liberal dressing of well-decayed manure and leaf-soil, adding a sprinkling of soot. This should be thoroughly incorporated with the soil with a fork, afterwards making the whole firm. The double varieties should be set out in rows with eighteen-inch spaces between them, and twelve inches apart. The singles, being stronger growers, will require a little more room. A good watering should be given when planting is completed, and they must not be allowed to become dry during the season or red spider will soon be in evidence. Avoid planting on hot dry borders. The following will be found excellent varieties: Doubles.—Mrs. J. J. Astor, Comte de Brazza, Marie Louise, Neapolitan, and Mrs. Hume Campbell. Singles.—Admiral Avellan, Princess of Wales, La France, and Baroness Rothschild. E. C. P.

DAHLIAS FOR GARDEN DECORATION.

In directing attention to some of the more useful dahlias for the production of rich colour effects in the garden, there is no occasion to refer, otherwise than briefly, to the desirability of efforts being made to materially increase the number of varieties of value for garden decoration. The great need at the present time is a race of dahlias that are free branching and profuse flowering, and bear their blooms on stiff, erect stalks well above the foliage; and, moreover, have a season of flowering extending about two months instead of a few weeks. Such race would be of enormous value in the assistance they would give in maintaining the attractions of the garden during August and September, and its creation appears well within the capacities of the raisers, having regard to what they have accomplished in other directions. There is no occasion that while endeavouring to improve the dahlia as a garden flower the raisers should relax in their efforts to add to the list of exhibition varieties other flowers of undoubted merit. There is an apprehension in some quarters that if greater interest is created in garden dahlias, and raisers devote attention to the improvement of them, the exhibition varieties would be more or less injured thereby. It is difficult to understand the ground on which such apprehensions are based.

CACTUS DAHLIA MRS. LANDALE.
A handsome garden and exhibition cactus variety, with rose-pink florets, yellow at the base, raised by Messrs. J. Cheal and Sons.

The extension of the cultivation of garden dahlias, and the improvement in the effect they produce, would certainly not lessen the interest in dahlia exhibitions, or in the varieties remarkable for the high quality of their flowers; whether it would lessen the demand to any considerable extent of the latter remains to be seen, but there can be no possible doubt that in the aggregate there would be a large increase in the annual sales. It should be remembered that there are two classes of dahlia growers; one consisting of those who devote their attention to the production of blooms for competitive purposes, and the other comprising those who grow dahlias wholly for the effect they produce in the garden. Hitherto the first of these two classes have had such liberal provisions made for them that they have had no cause for complaint, excepting, it may be, the difficulty which so great a plethora of good things occasioned when making selections. The other class of growers, which is by far the largest, have had to select as best they could from exhibition varieties, and very often made selections that afforded but little satisfaction or pleasure. The fact should be more fully recognised than has yet been the case that there are these two classes of growers, requiring varieties adapted to different purposes, and an endeavour made to meet their needs.

The improvement of the position of the dahlia as a garden plant does not wholly depend upon some change in the lines on which raisers carry on their interesting work. Much depends upon the general body of cultivators, and before we can hope to see the dahlia contributing its full share to the attractions of the garden there must be some changes in the method of procedure. In the first place, it must be recognised that the English summer is comparatively short, and that there must be delay in the plants reaching the flowering stage if they have to make growth after they have been bedded out that should have been made while they were in the preparatory stage. If this point is clearly understood cultivators who have to purchase plants will buy them in April, or quite early in May, instead of at the end of the last-named month, and within a few days of their being received shift them into six-inch pots. In these the dahlias will have ample extension for their roots, and if the compost consists of turfy loam, to which a rather liberal proportion of well-decayed manure has been added, they will continue in a progressive state until planted out in the beginning of June.

Plants raised by simply starting the roots early in March and thinning the growth to one or two, or dividing the roots into two or more portions with a growth attached to each, come into bloom rather earlier than do those raised from cuttings. This is worth remembering by those who require their dahlias in bloom very early in the season, and in connection with this point it may be mentioned that dry or pot roots can be purchased at the nurseries. This method of procedure has the advantage of simplicity and early production of bloom, but the flowers do not attain to so high a state of development as in the case of plants raised from cuttings in the customary manner.

In the preparation of beds and borders for garden dahlias a method of procedure somewhat different to that which would be advisable in the cultivation of dahlias for exhibition should be adopted. In the former case a short-jointed growth and an abundant production of flowers are main essentials, and these are best obtained by deep digging and moderate manuring. The quantity of manure to use in a given area will depend upon the character of the soil, and no definite advice can be given without a knowledge thereof, but it may be stated that those soils known to be impoverished, or which are light and sandy, will require about double the quantity necessary for deep, holding loams that have not had their fertility impaired by previous occupants of the beds or borders.

The question as to which of the selections should be given the greatest prominence is one that must be left to the taste of the cultivator. It may, however, be suggested that it should not, as a rule, be restricted to one or two, because of the increase in the interest and attractiveness where there is an adequate representation of the several classes. Comparatively dwarf-growing and free-flowering cactus varieties are especially adapted for garden decoration, and it is gratifying to know that the raisers have already made considerable progress in the improvement of the section for that purpose. Prominent among the newer varieties is White Ensign (Messrs. J. Stredwick and Son), a variety which marks a considerable advance; the plant has a bushy habit, and, as shown in the accompanying illustration, bears its large finely formed pure white flowers well above the foliage.

Flagstaff and Sweetbriar, from the same raisers, are also valuable for the garden. The first-named has rose and yellow flowers, and the blooms of the latter are a charming shade of pink. Mrs. Landale, with flowers suffused with bright rose on a yellow ground, and Mrs. J. H. Usmar, orange-yellow suffused with coral-pink, are two varieties raised by Messrs. J. Cheal and Son, and are both of much merit for the garden. Minerva (Mr. Charles Turner) is a new variety of quite distinct character, and should prove of immense value for the same purpose; the flowers are rather large, and the colouring a combination of apricot, yellow, and rose-carmine. Of the older varieties the following may be mentioned for their usefulness: A. D. Stoop, crimson-scarlet; Amos Perry, deep crimson; Avoca, crimson-scarlet; Dainty, yellow; Eclair, orange-scarlet; Effective, amber; Hon. Mrs. Greville, orange, suffused salmon; Mauve Queen, bright mauve; Mrs. H. L. Brousson, yellow, tinted salmon; Snowdon, pure white; Westhall Scarlet, bright scarlet.

To the list of decorative varieties two important additions were made last season. One of these was Brentwood Yellow (Mr. J. T. West), a remarkably free flowering variety attaining a height of about three feet; the blooms six inches and upwards in diameter, and of rich yellow colour, are borne well above the foliage. This is a most valuable addition to its class, and is especially adapted for bedding. The other is Loveliness (Mr. Charles Turner) a distinct free-flowering variety, the blooms of large size, and the colour soft rose-pink. A variety no longer new that should be grown in every garden where dahlias have a place is Kaiserin Augusta Victoria, a comparatively dwarf-growing variety, with medium-sized white flowers that are produced in profusion from July till the growth is cut down by the frost. It is surprising that so valuable a variety which has formed a highly attractive feature in the Royal Gardens, Kew, for several years, should have failed to obtain a place in the trade catalogues of this country. The illustration of a bed of this variety at Kew is from a photograph taken in October last. Mrs. T. Dorey, also grown at Kew with much success, is an excellent variety, rather dwarf in growth, and bearing flowers of good form and a pleasing shade of rose-purple.

The single varieties form an important group for garden decoration, but as they were dealt with by Mr. J. Cheal in the paper that has recently been published in these pages, and on another page of this issue, there is no occasion to refer to them here. Pompon dahlias are rather too formal to appeal to all tastes, but when grown in soil that is not too rich they bloom so freely as to produce an effective display of colour, and provide liberal supplies of blooms for decorative purposes in a cut state. Glow, rich coral, and Pink Beauty, blush-pink, are two new varieties of merit that have been introduced by Messrs. J. Cheal and Sons. Other varieties of merit include Annie Holton, Bacchus, Clarissa, Douglas, Elsa, Florence, Galatea, H. E. Searle, Ideal, Marietta, Mignon, Nerissa, Queen of Whites, San Toy, and Tommy Keith.

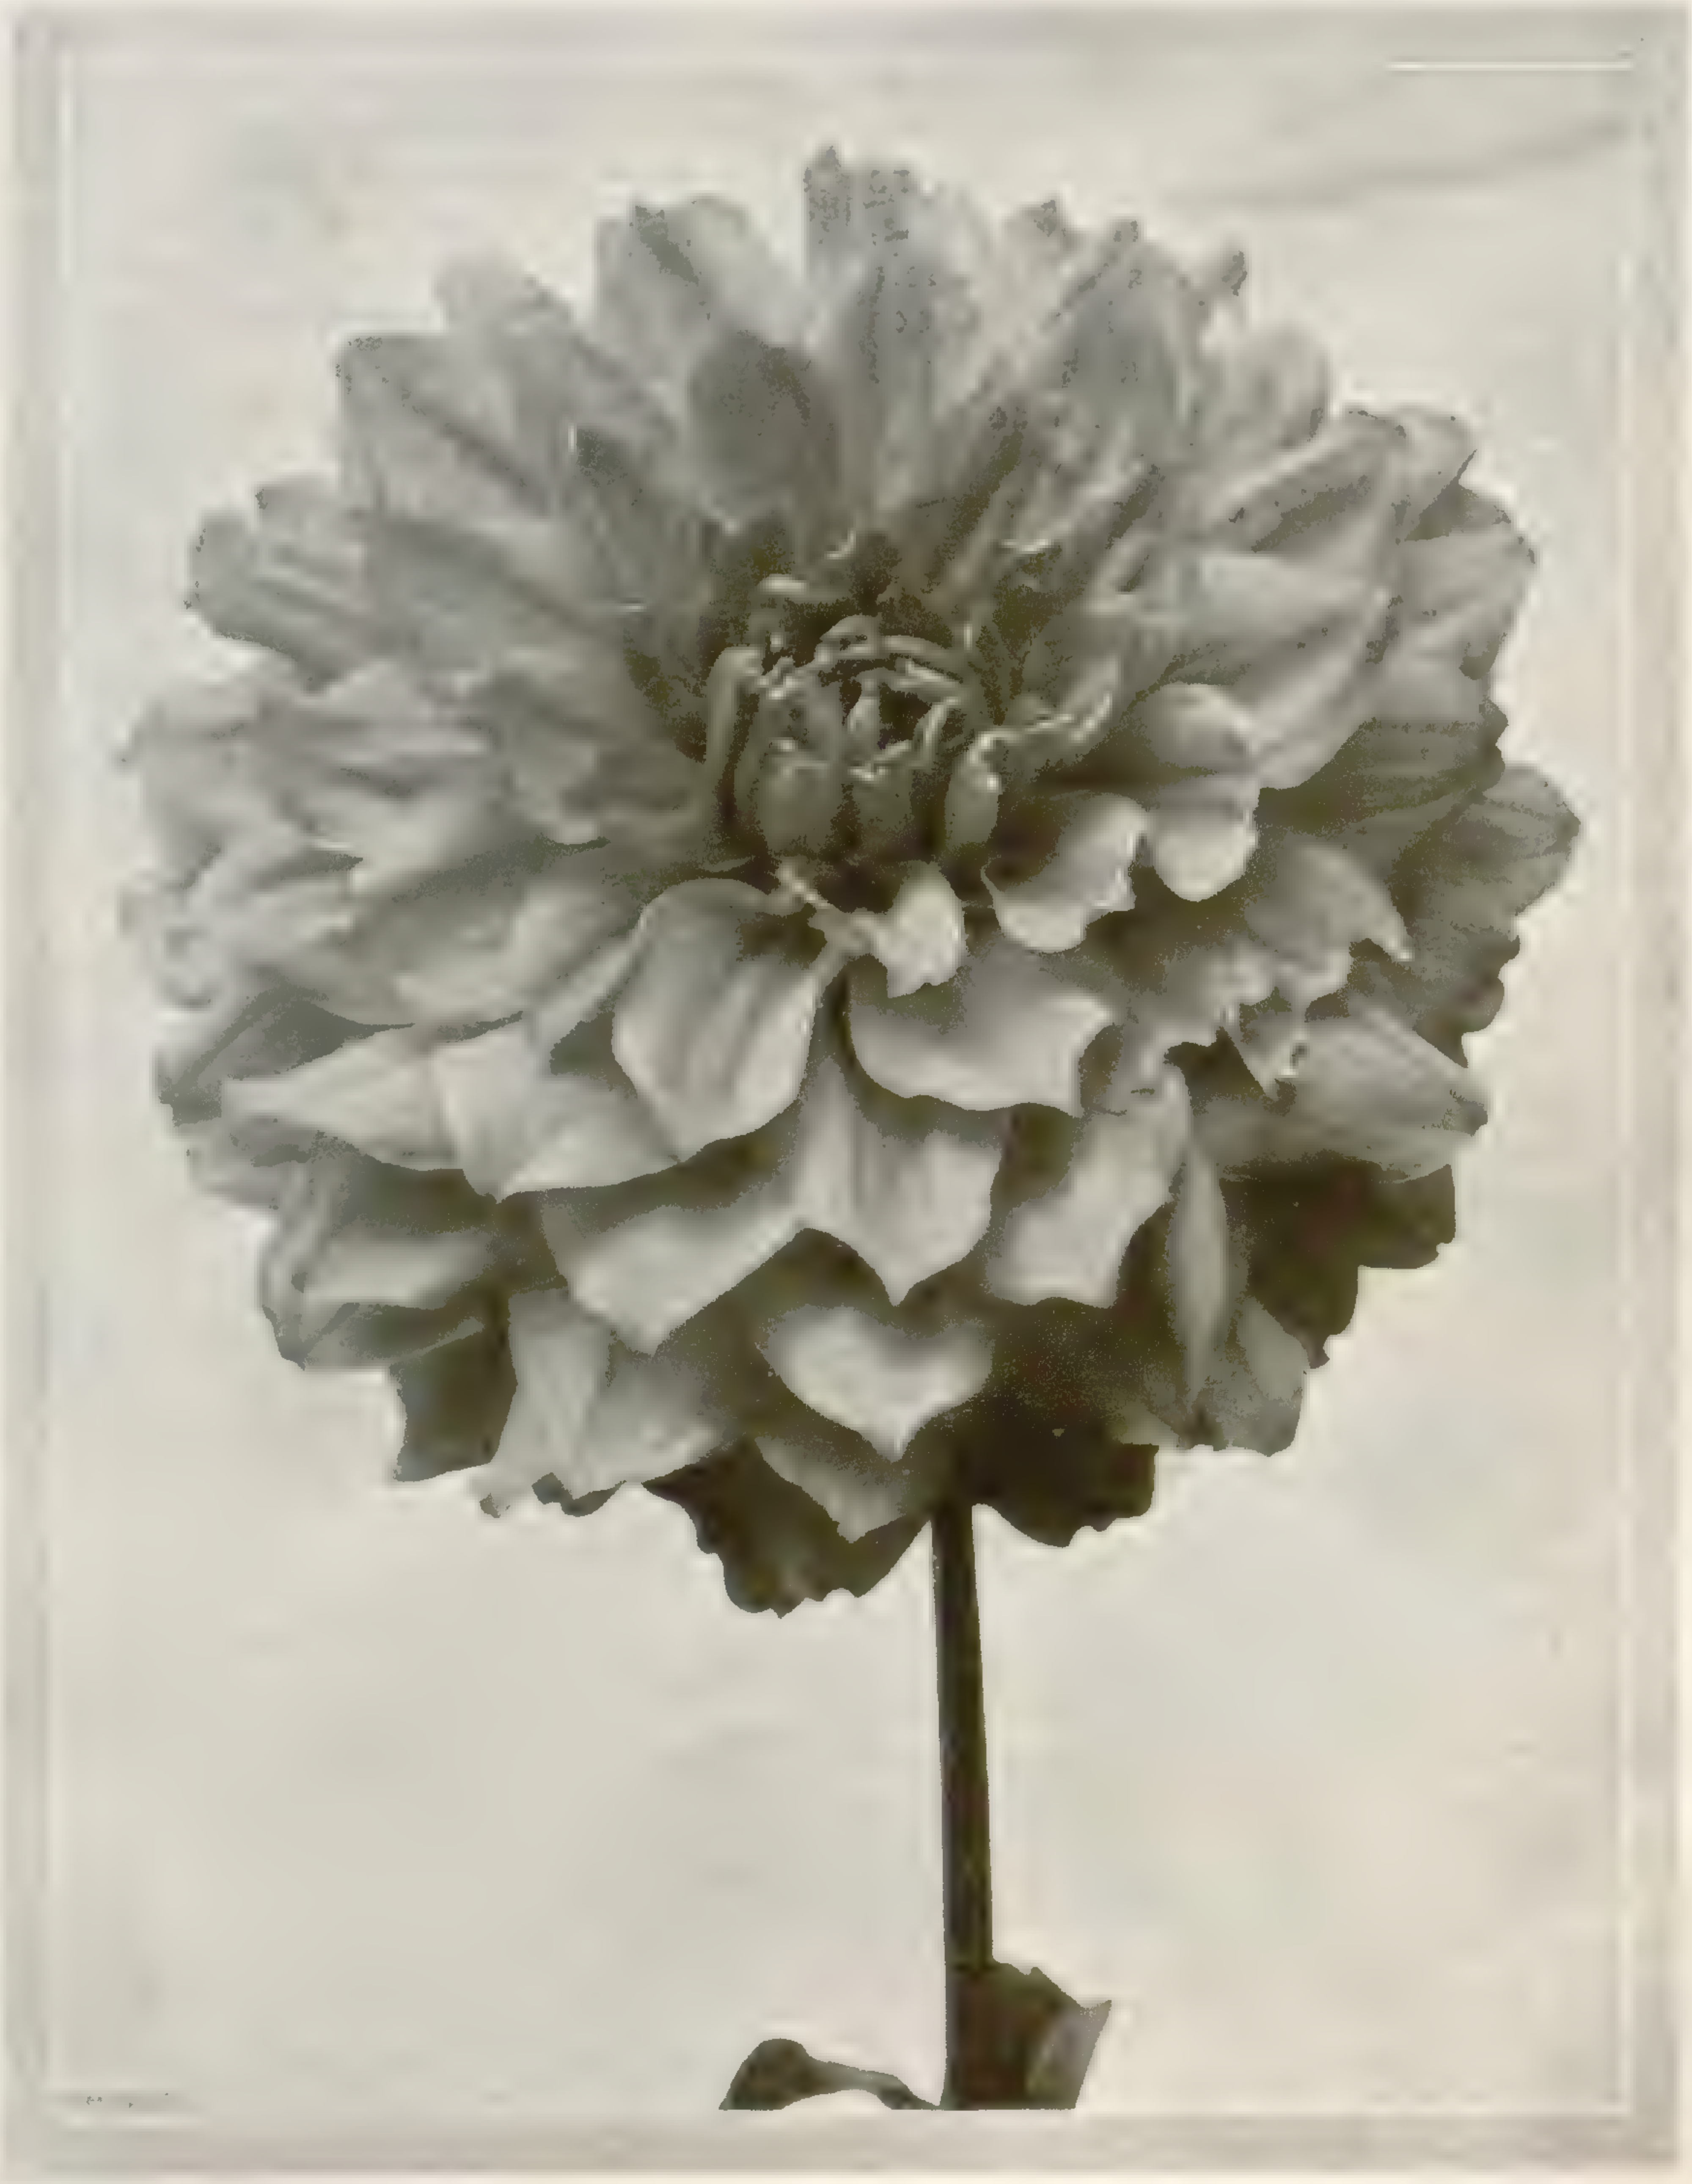
G. G.

For pretty gardens and lovely flowers read The Flower Garden, by T. W. Sanders, F.L.S. An up-to-date work on the formation, planting, and management of the garden, with description and cultivation of flowers and plants adapted for outdoor culture. Price 7s. 6d. net, by post, in box, 8s., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

FUCHSIAS FOR BEDDING.

With the present-day taste for a greater variety of subjects than was at one time employed for bedding out during the summer months, many different classes of plants previously little, if at all, used, are now much grown for the purpose.

Among them must be included the different forms of fuchsia, which are to be met with almost everywhere, and in many of our large public parks they form quite a speciality. Specimen plants from four to eight feet in height are particularly effective when plunged in the turf, especially in a grassy glade. In this way they should be disposed at such a distance from each other that their individual characters are retained, and yet not far enough apart to present a ragged appearance. Large specimens treated in this way last summer in Regent's Park formed a much-admired feature.



DAHLIA BRENTWOOD YELLOW.
A splendid decorative variety, with large rich yellow flowers, raised by Mr. J. T. West.

Next, beds are in many cases filled with fuchsias alone, and they are also largely used in association with other plants. For beds devoted entirely to fuchsias the larger and bolder kinds, such as Madame Cornellison, Marinka, Scarcity, Mrs. Marshall, and suchlike, are usually employed for the centre, surrounded by such kinds as Alice Hoffmann, or gracilis variegata, and edged with one of the coloured-leaved varieties, pegged down, to form a dwarf border.

Mixed beds of fuchsias and other plants admit of innumerable combinations, and these may be varied to any extent in order to suit individual tastes, for very few people see eye to eye in such matters. A particularly attractive series of beds, in which fuchsias played a prominent part came under my notice last summer. The fuchsias, in standard form, were disposed thinly in the beds, the ground underneath being carpeted with bedding violas. Springing from a groundwork of deep-coloured violas the light-tinted fuchsias had an exceedingly pretty effect, while the paler violas were overhung by the drooping flowers of the richer-hued kinds.

Coloured-leaved Fuchsias.

Last year a very pretty bed in Regent's Park was filled with fuchsias remarkable for the beauty of their foliage alone. Fairly large plants of the well-known varieties Sunray and Golden Treasure rose from an undergrowth of bushy plants of Fuchsia gracilis variegata, the whole being edged with a bronzy-crimson leaved variety—Meta, this last being pegged down. This combination of foliage varieties was certainly very pleasing, and admired by many. The natural habit of the fuchsia is such that its charms are displayed to great advantage when in an elevated position, for which reason some of the varieties are admirably adapted for furnishing vases, window boxes, and similar purposes. Those varieties of a somewhat loose habit of growth are seen to the best advantage when treated in this way.

Where glass accommodation is limited a desirable feature in connection with fuchsias is that even large specimens may be safely wintered where stood closely together, as being at that season devoid of foliage the heads do not take up much room. In spring they need to be shortened back into shape, and, with increased warmth and moisture, the young shoots will soon make their appearance. Then they must have more space assigned them, for the new shoots are exceedingly brittle, and will snap off if overcrowded.

Selection of Varieties.

Many of the new fuchsias of the present day are characterised by very large blossoms, which are much less numerous than those of a small or medium size. These large-flowered kinds are, as a rule, not adapted for summer bedding, as they are liable to be broken off by strong winds, and the loss of a few blooms is in their case severely felt. From this circumstance most of the popular bedding kinds are comparatively old varieties. Those of a self, or almost self, red colour are extensively grown, especially such as Marinka, Scarcity, Abel Carrière, and Monarch; while varieties with red sepals and petals and a dark or plum-coloured corolla, include Delight, Mr. King, President, Gertrude Pearson, Charming, Wave of Life, Lord Byron, and Abd-el-Kader. All these have single corollas, the double varieties from their weight, and consequent liability to injury, being but little employed for the purpose. Perhaps the most-grown of this class is Phenomenal.

Varieties with White Corollas.

The most popular variety of this section is undoubtedly Madame Cornellison, which was first sent out fifty years ago. It is of rather erect growth, with a corolla showing a tendency to become double, but not to a sufficient extent to form a weighty flower. This variety is also the hardiest of its class. A very desirable kind is the comparatively little-known Cadmus, which has a symmetrically shaped flower with a brightly-coloured tube and sepals, and a particularly clear white corolla. It is exceedingly floriferous, and, as noted at Peckham Rye Park last summer, bids fair to rival Madame Conellison in popularity. Among the best doubles of this colour are Ballet Girl, Duchess of Edinburgh, and Molesworth. Alice Hoffmann is a dwarf variety of this class.

Light-coloured Varieties.

The best of these are such old varieties as Amy Lye, Mrs. Marshall, Rose of Castile, and Lady Heytesbury. Lord Beaconsfield, the first of the group, with blossoms tinged with salmon, is still good, but it is less grown than Mrs. Rundle. A very promising member of this section which I have not met with elsewhere than in Regent's Park, is The Doctor, which is more floriferous, and has blooms of a brighter colour than those of the older kind.

Some distinct Continental hybrids sent out within the last few years have been tried for bedding, but they appear rather too delicate for the purpose.

Coloured-leaved Varieties.

These embrace Sunray, with leaves that become very brightly coloured under the influence of the summer's sun; Cloth of Gold, bright yellow; Meteor, reddish; Regalia, bronzy-yellow; Meta, bronzy-red; and the slender-growing Fuchsia gracilis variegata, a charming plant. W. T.

TUBEROUS BEGONIAS FOR BEDDING.

Where summer bedding is carried out to any great extent the present time will be a very busy one for the gardener, as the propagation and after cultivation of bedding plants take up much time and space, and the resources of many establishments are severely taxed at this season.

Among the various classes of plants used for the embellishment of the garden during the summer months none are more showy than the tuberous begonias, and very few, if any, take up less time and room in preparing them for bedding out. This in itself should commend them to those who have not a great amount of glass at their disposal, as when once there is a stock of tubers they may be used over quite a series of seasons, and need not be started into growth before the middle or end of March, or even later than this, so that at the outside they only require glass room for about ten weeks, and a cold frame, with the help of a very mild hotbed, will suit them quite as well, or even better, than a greenhouse.

There are one or two very good named varieties that are used for bedding, notably Lafayette (scarlet) and Major Hope (salmon-pink and white), while the old variety Worthiana is not to be despised, and these then make really effective beds either planted by themselves or in conjunction with some other bedding plants; the two former are made very good use of in this way at Hampton Court Palace gardens. But, generally speaking, these named varieties are not so robust and easy to grow as are the seedlings, the former, of course, having to be propagated from cuttings or by division of the tubers, which naturally weakens the constitution considerably, hence they are not so frequently met with as their brilliance and beauty would warrant.

Seedling begonias are very strong and free flowering, and as they may now be had in a great many colours and shades, from pure white to deep crimson, each of which will come practically true from seed, the expense of raising a batch of these beautiful bedding plants cannot be complained about, and if an early start is made plants may be raised from seeds and bedded out the same year, but it is from second and third year tubers that the best results are obtained.

The raising of begonias from seeds has often been explained in these pages, and it is only necessary for me to say that the seeds should be sown quite by the end of January, and, as soon as large enough to handle, the young seedlings must be pricked off, thereby avoiding any loss of plants by damping; this operation must be done two or three times, and at each successive pricking off give the young plants a little more room. The compost used must be light and open, and a fairly brisk temperature employed until the leaves are about two inches across, when they may be hardened a little. Assuming that up to this point boxes have been used, the plants may with advantage be removed from these and planted out from four to six inches apart in a frame on a hotbed, or in one which has a hot-water pipe or two running through it. As soon as they take hold of the soil in the frame the young plants sould be inured to a little more air, and any shading that may have been found necessary should be gradually removed until the begonias will stand full exposure to light and air.

From these frames they may be removed with a good ball of soil to the beds or borders in which they are to flower, and in this manner I have found them grow away much better, and without any check, than when they have been planted out from pots, and if they have been well managed they should be really good plants almost ready to throw up flowers by the second week in June, and this is about the date when it is really safe to plant out begonias in a great many districts.

Though seedlings may be raised in this manner and bedded out the first season, it is really better to plant them in specially prepared beds in the kitchen garden, or some other suitable place, where they may flower and be proved, and select them to colour for the following and subsequent seasons, and this will save the bother of having perhaps a few mixed colours in the flower beds, where they would spoil an otherwise effective colour scheme. For starting these tubers the second year I certainly prefer a mild hotbed or pit heated with hot water, placing them at the proper distance apart in three or four inches of suitable soil about the middle or end of March, and if kept fairly close till growth commences, afterwards keeping them thoroughly exposed to the sun and air, as the weather permits, they should have made fine sturdy plants about six inches high by the date previously mentioned.

To be really successful with begonias as bedding plants some consideration must be given to the position of the beds, or the results may not in all cases be quite satisfactory, and though they will in most seasons stand bright sunshine, there are certain positions where it would be fatal to plant them, such as a bed which is exposed to the sun, and where a cold or drying wind is likely to reach them, or a border which is sheltered from sunlight in the morning, and yet gets the full blaze in the afternoon; in either of these positions it is more than likely the foliage will be much burnt, and whenever this happens the beds are spoiled for a considerable time, and the check is so great that the plants take a very long time to recover.

But wherever the beds are not exposed to the wind, and where they are on a fairly low, damp position, they will succeed admirably, provided proper attention is given to the preparation of the soil, and even if the beds are in a semi-shady position it will be no detriment to them, but rather the reverse, should the season turn out to be very hot and dry. In heavy soils begonias are rather a long time in starting, and, when they become established, grow very soft, so that a moderately light rich soil is to be preferred for them. Plenty of water should be given after planting to ensure them having a good start, as well as right through the season.

As the plants grow it may be found necessary to put a stake to each growth to prevent damage by wind, etc., but if a proper strain has been selected it will not be necessary to stake the blooms, as they should stand erect, and be well clear of the foliage right through the season.

As mentioned earlier, there are many distinct shades of colour, all of which are beautiful, and it is easy to select the colours that please the individual, but probably the most popular are the scarlets, bright pinks, yellows, and whites, and I certainly think that they are most effective when planted in beds separately, with just an edging of some other bedding plant. If the beds are fairly large the addition of a few dot plants, such as acacias, eucalyptus, fuchsias, abutilons, Zea japonica, etc., etc., will do much to enhance the general effect.

Thomas Stevenson.

LARGE SUMMER BEDS.

In view of the fact that gardeners will soon be directing their attention towards the furnishing of flower beds for summer display a few remarks and suggestions as to the treatment of large beds may prove of service. Where space will admit a series of beds of spacious dimensions it is possible to produce both an imposing and artistic effect, and to this end plants of large growth must be pressed into service.

AN EFFECTIVE BED OF LANTANA ELEGANTISSIMA IN HYDE PARK.

A free-blooming plant with bluish mauve flowers.

It is difficult to understand why fuchsias in standard form are not more extensively employed as bedders, as it is difficult to conceive anything at once more graceful and beautiful. Further, we have learnt how to produce them in the course of a year, while in the second season they resolve themselves into splendid specimens. As seen employed towering above violas that provide a pleasing colour contrast or harmony we get a fine effect, and the same applies when Phlox Drummondi, verbenas, Callistephus sinensis, etc., are employed as a carpet. Pyramid fuchsias find many admirers, and wonderfully fine examples are seen in the London parks and gardens, and while nothing, to my mind, appear so happy or effective as violas as an undergrowth, the changes may be rung in carnations, asters, stocks, mimulus, mesembryanthemums, etc.

Groups of three plants each of specimen Heliotrope President Garfield, or other good named varieties, and Strepsolen Jamesoni, arranged alternately, the intervening space being filled in with Coreopsis grandiflora, with a framework of purple violas, is to be recommended, as is also Cuphea platycentra and Calceolaria Burbidgei arranged in the same way, Verbena venosa doing duty as a carpet, and Verbena Defiance to complete the picture in a foot-wide belt.

I noted a bed last season planted with Swainsonia galegifolia and Eulalia zebrina, backed up with a splendid strain of salpiglossis, and three rows of Dianthus Fireball as an edging, and was much impressed with the effect created.

The old school of gardeners would rub their eyes in amazement if they happened upon Stephanotis floribunda perfectly happy in the flower garden, and yet some beautiful examples were seen in the Hampton Court Gardens a year or two ago, and the air was redolent with their delicious fragrance, in combination with that emitted by the Polyantha roses and mignonette, also tenants of the bed in question.

The lantanas, as seen in large specimens, strike a beautiful and distinct note, and perhaps the finest for our purpose is shown in the illustration, namely L. elegantissima. Kœniga maritima and Antirrhinums Queen Victoria and Queen of the North, both of spotless purity, form a fine carpet for these plants, while the Nicotiana affinis hybrids are also to be recommended.

Plumbago capensis is indispensable, and apart from the fact that we have too little of its colouring in our gardens, it luxuriates and blossoms with freedom if given a sheltered position I have seen it associated with huge plants of Campanula pyramidalis and Verbena Lovely Blue, the edging being made up of violas of softest blue, and the effect was rich and pleasing. A huge bed in a western country garden was rendered conspicuous by the fact that it contained all white flowers. Very large plants of Bouvardia Humboldti corymbiflora, Campanula pyramidalis alba, the white counterpart of Plumbago capensis, and groups of Galtonia candicans towered above white violas, Gnaphalium microphylla and Kœniga maritima, with three rows of Centaurea candidissima compacta as edging.

It is superfluous to dwell upon the merits of ivy-leaved pelargoniums, when grown into pyramids ranging from three to six feet in height, and nothing, to my mind, is more effective than varieties of suitable shades with which to cover the ground. Effective is the association of Fuchsias Marinka and Mrs. Marshall with Pelargonium Madame Crousse, with a groundwork of fibrous-rooted begonias, and the same applies to large plants of Erythrina crista galli, in company with blue violas and white carnations.

Where standard heliotropes are available let them be associated with Carter's Monarch stock, a magnificent variety, which produces a single spike of pure white flowers 2½ feet in length. In the case of pyramids, Mont Blanc stock, of great purity, or, perhaps, Princess Alice, which remains in beauty over a long period, may be employed. Very fine must be written against specimen plants of Hydrangea paniculata grandiflora, Agapanthus umbellatus, and bold groups of Canna President Faure, with an eighteen-inch belt of Veronica Andersoni variegata, silver-leaved geraniums in standard form, with a mass of bronze-leaved cannas or Lobelia cardinalis Firefly, edged with Fuchsia Meteor; Paul Crampel pelargonium, with Antirrhinums Queen of the North, or Yellow Queen, and Verbena venosa; while white pelargoniums with Lobelia tenuior and rose-coloured dianthus cannot fail to please or to arrest attention. With the wealth of material we have at command monotony is out of the question in present-day flower gardening.

Walter H. Aggett.

TENDER FINE FOLIAGE PLANTS FOR SUMMER BEDDING.

Of the different subjects grown for summer bedding the choice is by no means limited to flowering plants, as many depend for their attractiveness upon their brightly-coloured or otherwise ornamental foliage.

Those in which the leafage is of a plain green tint, are, in some respect or other, decidedly ornamental, and apart from their intrinsic beauty, they frequently serve as a foil to brightly-coloured associates. Some, such as the wigandias, ricinus, and Polymnia grandis, are remarkable for their stately grandeur, while others are decidedly graceful in habit. In stature, too, they vary considerably, from the two or three inches of the alternantheras to the dozen feet or thereabouts of the plants just above-mentioned.

It is to these larger and bolder subjects that my remarks more particularly apply, for the choice of such plants is an extensive one. Among the best are Acacia lophantha and Acacia dealbata, with prettily divided foliage, the last-named being of a glaucous tint; Artemisia judaica, a quick-growing annual, with gracefully cut and silvery foliage; cannas, remarkable nowadays for their handsome flowers as well as their ornamental foliage; Cannabis gigantea, the Giant Hemp, with prettily cut foliage; Chamæpeuce cassabonæ (Fish-bone Thistle), and Chamæpeuce diacantha, two striking plants; Cordyline australis, hardy in favoured districts; Ferdinandia eminens, remarkable for its huge leafage; Gnaphalium microphyllum, an upright-growing plant with small silvery leaves; Grevillea robusta, well known for its pretty fern-like foliage; Kochia trichophylla, which has of late years become very popular; Melianthus major, with prettily divided, bluish-green leafage; nicotianas, some of which have very large, handsome foliage; Perilla nankinensis, deep purple leaves; Polymnia grandis (syn. Montanoa bipinnatifida), with large, much-divided foliage; Ricinus (Castor Oil Plant), majestic plants with noble leaves, which, in the different varieties, vary in colour from light green to dark purple; solanums, of which there are many striking kinds; wigandias, sturdy growing plants with noble leaves; and zea (maize), of which there are some beautifully variegated forms. In their earlier stage these do not show their true character, hence it is necessary not to condemn them too hastily.

With such a large choice of subjects as enumerated a vast number of combinations may be carried out. Such plants as the nicotianas, castor oil plants, cannas, and maize are seen to great advantage when occupying an entire bed, as they possess a massive grandeur of their own. The more slender-growing giant hemp, on the other hand, may well be employed for breaking up too dense a mass of foliage.

A very striking bed, noted by me, was planted with a dark-coloured ricinus, and the white-foliaged Solanum marginatum alternating with each other, the whole being margined with Solanum Balbisi, which has prettily-cut foliage and reddish spines.

The different subjects here mentioned can be readily raised from seeds, and, what is more, if sown early in the spring most of them are available for bedding out the same season. They are for the greater part natives of the Tropics, hence they need a warm structure during their earlier stages.

Of slower growth, and to which these last remarks do not apply, are the acacias, chamæpeuce, Gnaphalium microphyllum, and Grevillea robusta, while for the kochia only gentle heat is needed. The cannas, too, though effective the first season, are much stronger and more showy the second year.

Tender plants, for the most part of considerably lower stature, and grown principally for the sake of their bright-coloured leafage, would include the alternantheras, so valuable for carpet bedding; Amaranthus melancholicus ruber, with deep red leaves; Amaranthus salicifolius, whose leaves are marked with red, yellow, and green; begonias in variety; coleus, of sorts; iresine, in variety; Leucophyton Browni, a pretty silvery plant; and variegated-leaved pelargoniums. These are for the most part readily increased by cuttings, while old plants of alternanthera may be propagated to almost any extent by division.

T. C.

PELARGONIUMS IN THE FLOWER GARDEN.

I think I am right in stating that no other class of plant has enjoyed such popularity for summer bedding as the pelargonium, but it is not used so extensively now as it was at one time, owing to the introduction of more varied ideas and tastes into the flower garden. The tricolor and bicolor section appear to have suffered most through this change, while the zonale and ivy-leaved sections are still largely used, and with good effect.

Ofttimes we hear objections raised regarding the use of pelargoniums for bedding purposes, on account of the beds presenting a flat and stiff appearance; then, again, we are told that after the first lot of flowers is over we get nothing but rank growth, with a few straggling trusses of bloom, and also that at a time when the beds ought to be at their best they have to be disfigured for the purpose of procuring cuttings for the following year's stock. Probably these complaints carry some truth with them in a few instances, but where a little care is exercised in the selection of varieties, also in the method and manner of planting, no other summer bedding plant gives a more pleasing and lasting display.

Much may be done to relieve the flatness of beds by using plants two or three years old, as these, with very little trouble, can be grown from three to five feet in height, and even taller, if desired, especially the ivy-leaved varieties. To obtain these some of the best plants at the end of their first season's growth should be put into six-inch pots, and be kept rather dry in a cool house until early in the New Year, when they should be given more moisture at the roots and an increased temperature to encourage a free growth. As soon as new growth begins they are shifted into nine or ten-inch pots, and kept growing in a gentle heat until it becomes necessary to harden them off previous to putting them into their summer quarters. Plants treated in this way flower more profusely than young plants, giving a wealth of blossom all the summer through, and by their increased height make good specimens for dot plants in large beds. They may also be used to raise up the centre of a large bed, or in cases where it is desirable to have a group of pelargoniums in a flower border these tall plants will be found most useful for planting at the back. Old plants of the ivy-leaved varieties are almost indispensable for furnishing vases on terrace walls, etc., and when put into the vases they can be loosened from the stakes supporting them and allowed to hang down naturally, thereby furnishing the vases at once, otherwise, by using young plants for the same purpose, it takes them the greater part of the season to produce the desired effect.

When a little judgment is used in preparing the beds which pelargoniums are to occupy throughout the summer much can be done to check rank growth, and to induce the plants to flower freely. The soil should be light and firm, using manure only in places where the soil is of a very poor character. Too much water is often responsible for indifferent results; once the plants become settled very little is needed in most instances, unless an unusually dry time is experienced.

Usually, when bedding out is completed, there are a quantity of surplus plants to spare, and these, if planted in some vacant quarter, will give many cuttings for stock, while if the beds are examined at intervals many cuttings may be taken from the plants without making any appreciable injurious effect.

As it comes to my lot to arrange for the herbaceous borders to be kept as full and gay as possible from spring until the autumn, I have often found old plants of pelargoniums extremely useful for filling gaps caused by the early and short season of some of the occupants. Plants of a scarlet variety fill in splendidly where the Oriental poppies have passed out of flower, and those of a white variety can be used among doronicums and lupins, helping, rather than upsetting the colour arrangement of the border.

The following pelargoniums can be depended upon to give satisfactory results. Amongst the zonals are Paul Crampell, Reformator, Henry Jacoby, F. Raspail, and Mrs. Lever. Ivy-leaved: Madame Crousse, Souvenir de Charles Turner, Galilee, and Gordon Glory.

T. B. Field.

PIERIS JAPONICA.

Although there are several species of pieris cultivated in gardens, the most useful will probably be found in P. japonica, for though P. formosa, the Himalayan and Chinese species, is a larger growing shrub, and bears finer inflorescences, it is less hardy, and may only be successfully cultivated in those places where severe frost is not experienced. The species under notice is a native of Japan, and is often grown in companionship with the North American P. floribunda. It may be readily distinguished from the American plant, however, by its larger and glossier leaves, and by its longer, pendulous racemes of white flowers. As an evergreen it has much to commend it, for it grows into a shapely bush three to five feet high. The buds are formed during autumn, and lie dormant all winter to expand during late March and early April.

A well-flowered bush forms a conspicuous object, for the drooping panicles are from four to six inches in length, and borne with great freedom. It thrives under similar conditions to rhododendrons, but must not be planted in places where lime is prevalent in the soil to any appreciable extent. The best results are obtained from plants grown in groups, either alone or associated with other peat-loving subjects. During early life growth is very slow, and those plants which are grown from seeds take a considerable time before they are large enough to transfer to permanent positions.

W.

BEDS FOR DWARF SUMMER FLOWERS.

Plants of comparatively dwarf habit are eminently adapted for filling flower beds of medium size, and by bringing together subjects that are dissimilar in growth and colouring charming effects are produced. The order of the day forbids heavy and solid masses, and we are called upon to paint the picture with a light hand. One is led to wonder, in view of the vast improvements that have been effected in garden decoration in recent years, why this artistic perception was not more fully developed at an earlier date.

I propose to submit a few particulars of combinations of plants that struck me as being both pleasing and effective during the summer of 1910, and at the outset I would strongly advise that the dwarf and very beautiful annual Delphinium Blue Butterfly be associated with Antirrhinum Queen Victoria, of spotless purity. Rich purple violas form a capital edging to such a bed, and a few dot plants of Zea gracillima variegata will enhance the beauty of the whole. We are agreed that tuberous begonias present a somewhat heavy appearance en masse, and it was a happy inspiration to allow Iceland poppies to rub shoulders with them, being fairly evenly distributed over the whole bed; Eulalia gracillima variegata and Grevillea robusta were also pressed into service, and the result was a light and graceful whole. One cannot conceive anything more lovely than a combination of Celosia plumosa and Lilium lancifolium rubrum, L. album, and L. roseum, and what a splendid finish does Viola Lilacina make. What shall we say of Salvia Glory of Zurich as a decorative subject? Surely it has no rival for extreme brilliance, and just the softening effect desired is afforded by the presence of the wiry and silvery-white Leucophyton Browni, while dark blue violas appear at their best when employed in their company.

The old and meritorious pelargonium, West Brighton Gem, appeared in a new light, as seen arranged in raised groups of irregular size and outline, masses of Viola Ardwell Gem being employed in the intervening spaces. Very fine was a bed of choice double pyrethrums, and in close proximity a glorious mass of single kinds demonstrated their value, not only as early bedders, but to supply a wealth of cut flowers. Later, these were returned to the reserve garden and cockscombs thinly disposed, and carpeted with Lobelia Snowball, appeared upon the scene to create a rich effect.

Fibrous Begonia Erfordi was associated with Mesembryanthemum cordifolium variegatum, Kochia trichophylla doing duty as dot plants, the framework being blue verbenas. Begonia Major Hope, soft rose-pink, with Gnaphalium microphyllum interspersed, and a few two-feet high standards of Veronica Andersoni variegata looked well. A bed of Dianthus in both double and single forms, violas of various shades being freely interspersed, arrested my attention, and how very happy these plants appear so placed, and nothing better could have been found than Dactylis glomerata as an edging. An arrangement of Phlox Drummondi, in which groups were trained upright, the remainder being pegged close to the ground, made it clear that these old flowers yield to none from a floriferous point of view, while they contribute colouring as diverse as it is beautiful. Balsams arranged at eighteen inches apart, with a groundwork of Alternanthera magnifica and aurea, presented a formal appearance, which the silvery grass edging did something to redeem. By all means plant a bed with Lobelia Firefly, Lilium longiflorum, and Kœniga maritima, with Cliveden Blue viola as an edging. I noted such a bed in a public garden on the South Coast last season, and there was nothing to compare with it for fine effect.

Cineraria maritima, Iresine Lindeni, Amaranthus melancholicus ruber, the Crystal Palace Gem pelargonium, with two rows of Coleus Verschaffelti, constitutes a first-rate foliage arrangement for a medium-sized bed, and Dracæna indivisa may be allowed to tower above them. Fuchsia Ballet Girl, in company with Viola Sir R. Buller, looked well, with a few plants of Solanum pyracantha arranged between the rows of lobelia edging. Fuchsia Marinka, with the white sport from Pentstemon Newbury Gem, variegated geraniums in variety, with gold and silver abutilons freely interspersed amongst them, was another notable arrangement. Stocks arranged in a colour scheme, to be succeeded later by early-flowering chrysanthemums, dahlias from pots, etc., are to be recommended, while those who are wise in their generation will not fail to devote a spacious bed, situated in a prominent position, to Anchusa italica Dropmore variety. The finest examples I have seen of this beautiful plant were noted in Aldenham House Gardens, and I am reminded that when visiting another very large garden about the same time the man at the helm there was content to regard it as a respectable kind of weed. For some reason or another it was very unhappy in this garden, yet so fine at Aldenham.

A. H. W.

AN EFFECTIVE BED OF DWARF PLANTS AT HAMPTON COURT.
The plants consisted chiefly of Leucophyton Browni and Salvia splendens Glory of Zurich.

LAWNS.—Those who desire to make a new lawn or bowling green, or to renovate and maintain existing ones in good condition, can have no better guide than "Lawns and Greens," by T. W. Sanders, price 1s. net, by post 1s. 2d.; bound in cloth 1s. 6d., by post 1s. 9d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

TREATMENT OF SEEDLINGS.—Many seedlings will now be showing signs of growth, and, as it is essential that the plants should have every inducement to grow, any potting necessary should be attended to before the young growths and new roots become far advanced. Calanthes which have just made their first bulb, if grown under favourable conditions, quickly commence growing with the return of favourable weather outside. We find that very considerable progress is made with the second growth, and many of the plants are induced to flower on completion of this growth. It is well, therefore, when repotting, to give the plants ample root room, or a second potting will be necessary later in the season. If loam is used for seedling calanthes, it should be of a very light and fibrous nature; we prefer to use peat, chopped sphagnum, and some broken leaves, mixed with finely broken crocks and sand. Place the plants in a position within reasonable distance of the glass, which will prevent them becoming unduly drawn and weakly.

DENDROBIUMS.—Where the conditions are favourable, no orchids are more easily grown than seedling dendrobiums. From the early stages of germination they make rapid progress, and in most cases a good pseudo-bulb is procurable the first year. The plants do not require a great deal of root room—in fact, they resent much compost about their roots. It is essential to have ample drainage, and to see that the potting compost is of a porous nature. Equal portions of fibrous peat, osmunda fibre, and finely-chopped sphagnum moss, with some broken charcoal intermixed, is suitable. This should be made firm about the base of the plants. It is advisable to attend to potting before the new roots become far advanced, as they are very brittle and subject to injury.

CATTLEYAS, and their allied genera, have of late years been raised in greater numbers than perhaps any other class of orchids; and, as their requirements are now pretty generally understood, I need not refer to the details, but must impress my readers with the fact that, if it is desirable to flower seedlings in anything like a reasonable period after seed-sowing, the plants must be kept growing practically at all seasons of the year, right up to the time they reach the flowering stage. It was the attempt to imitate Nature that prolonged the flowering of this class of plants for a number of years, and the resting season, assumed to be desirable under natural conditions, may be ignored under artificial treatment; and it is well to keep this fact in view, and to give the plants every facility for free growth. The present season is one of the most suitable to attend to potting among the plants of various ages. After potting keep the atmosphere humid about the plants. In some situations damping the floors, etc., at night may be beneficial. Protect from strong light until the new roots become established in the new potting compost.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

SHOW PELARGONIUMS.—These most useful plants are now showing their flower buds, and will be greatly assisted in their development by occasional applications of weak liquid manure. Plenty of ventilation is necessary, as pelargoniums greatly resent a close atmosphere. This section of the family is very much subject to attacks of green-fly, so that they must be fumigated at intervals to prevent damage, especially before taking them into the conservatory to form a display.

ZONAL PELARGONIUMS.—Cuttings of the zonal section which were inserted several in a pot ought now to be ready for potting. Make the soil moderately firm to induce sturdy growth. Careful watering is necessary at this stage. When the plants have become established after potting they should have the tips removed to make the plants branch.

HELIOTROPIUMS.—These are always acceptable as subjects for the conservatory on account of their fragrance. They may be grown as climbers, bushes, or standards, but undoubtedly the flowers are shown to greatest advantage when they are grown as standards. Cuttings may be put in now in a good brisk heat; when rooted, pot off singly into small pots, and keep them growing steadily by subsequent pottings. Grow to a height of about three feet, when the point should be pinched out. Remove all the side buds to within a short distance from the top; and as the remaining shoots develop they must be pinched to form a head. In the summer time the plants may be placed outside to derive full benefit from the sun. Fuchsias may also be treated in the same manner as advised for heliotropes.

BROMPTON STOCKS, which have been wintered in frames, are now showing their flower spikes. Remove a few into a slightly warmer place to provide early flowers, which will be found very acceptable. A little liquid manure will be very beneficial.

CUTTINGS AND SEEDLINGS.—One thing above all others which is necessary in successful plant culture is a good foundation. This can only be obtained by careful and ready attention to all details when the plants are in a young state. Rooted cuttings must not be allowed to become matted together before being potted off, or a serious check will be the result from which it is hard for the plants to recover. Seedlings must not be allowed to become crowded in the seed pans or boxes, but be pricked off or potted to keep them continually growing. It is this continual growth which builds up the strong constitution of the plant necessary to give the best results in flowering. Keep all seedlings and cuttings as near to the glass as possible to prevent them becoming drawn or "leggy"; shade from hot sunshine. —A. Grubb, Porter's Park Gardens.

HARDY FRUITS.

STRAWBERRIES. — Strawberry beds should now receive attention; they should be hoed through, have all weeds raked off, and given a good dressing of lime and soot as a preventive to slugs. Then add a thick layer of clean wheat or barley straw, worked well under the folage, to prevent the fruits from getting damaged by damp, or splashed with soil from heavy rains. Where there are handlights or frames to spare these may be placed over strong crowns of last season's planting, thereby advancing the crop quite a fortnight over those not protected. Extra attention will be well repaid; if the fruits under cover are slightly thinned and a good soaking of liquid manure given occasionally the crop will be improved.

BORDEAUX MIXTURE.—Apple and pear trees that are subject to scab may be sprayed with this mixture immediately before coming into flower. Bordeaux mixture is the best known remedy at present for this most disfiguring disease, which not only spoils the crop but is in a great measure responsible for the unhealthy state of some of the weaker and more delicate varieties of our principle hardy fruits. When using the mixture a careful memoranda should be kept of results obtained, as some varieties of apples may show slight injury to the foliage, and some also a slight russeting of the fruits. This may sometimes be due to the weather, or other causes, but if ordinary care be used in the mixing and application of the fungicide very little injury, if any, will be caused.

PREPARING BORDEAUX MIXTURE.—The most convenient way of preparing the mixture is to make 50 or 25 gallon lots, according to convenience or the size of the spraying machine, using at the rate of 4lbs. of sulphate of copper and 4lbs. of quicklime to 50 gallons of water. The sulphate of copper may be readily dissolved with a little hot water, and made up to 25 gallons; the lumps of lime—which must be quite fresh, or the mixture will be spoilt—should be allowed to "blow" in a little cold water at first, afterwards making up to 25 gallons. Both lime and copper solutions should then be poured simultaneously into the spraying machine, straining at the same time through a piece of gauze or sacking. Use at once, and keep it well stirred as the work proceeds.

SPRAYING.—The mixture should be applied through a very fine nozzle, and with sufficient force to cause a fog or smoke like spray, and on no account should the application be so heavy as to cause a drip from the leaves, or injury is sure to follow. Cox's Orange Pippin should be sprayed with the mixture at a slightly reduced strength, and, if it is thought necessary, give a later spraying when the fruits begin to turn eye downwards, as on very young fruits the spray will sometimes cause a russeting. — J. Whittle, Cheveney Gardens.

THE KITCHEN GARDEN.

CAULIFLOWERS. — The early - raised plants may now be safely planted out. A considerable portion should be given a warm situation to forward their growth, as these will be found useful to succeed the spring broccoli. The remainder may be given a more open quarter, to yield a lengthy supply of heads. Select ground that is sweet and in good heart, and give a distance between each plant of about eighteen inches. Should the weather prove cold afford the plants shelter for a time by placing laurel boughs in position to break up the winds.

BROCCOLI AND WINTER GREENS.—The principle sowing of these may be made. Select a piece of ground that has not carried crops of brassicas for some time, and is openly situated. Give a dressing of lime and wood ashes to its surface, forking it lightly in. Draw out the drills at one foot apart, and sow the seed thinly. The two most hardy and reliable varieties of late broccoli for this part of the country are Veitch's Model and Sutton's Flower of Spring.

MAIN CROP POTATOES.—It will be advisable to proceed with plantations of main crop varieties of potatoes. If the sets have been prepared by being picked over, removing the weakly and small shoots and retaining one or two of the strongest, keeping them in a cool, airy place, it will much assist matters in securing a desirable and even growth fit for planting. Potatoes require a rich and thoroughly worked soil. If manure has been scarce give a dressing of bone-meal and wood ashes along the drills at the time of planting. Give a distance of not less than two feet from row to row. Strong growers may require two feet six inches, and about a foot apart in the row. For winter supplies I pin my faith to Up-to-Date and Scottish Triumph for latest use.

ASPARAGUS.—A stock of young plants is mostly necessary either for forcing purposes or for renewing beds that are past their best. Where ground has been trenched and enriched with manure, wood ashes, etc., to bring it to a suitable condition, seeds may be sown in drills two feet apart. Where land is naturally suitable there is no reason why permanent beds should not be formed in this way directly from sowing, and so save the labour of replanting. Do not sow the seeds thickly; liberally thin out the young plants as soon as the strongest can be selected to about twelve inches apart.

SEAKALE.—The thongs that were saved when lifting the crop for forcing, if cut into lengths and stored in sand or ashes, will be now in condition for planting. Ground that was dug early and left to the influence of wind and frost will crumble down to a powdery surface it lightly forked over; apply a dressing of salt at this time. Plant in rows from fifteen to eighteen inches apart, and allow one foot between the plants in the row. Place the top of the thongs even with the surface of the ground, and make it firm.

GLOBE ARTICHOKES.—If fresh plantings are required this may now be carried out, either by the removal of healthy suckers from the old stools or the purchase of new stock.—C. Flack, Cholmondley Castle Gardens.

FALMOUTH SPRING FLOWER SHOW.
THE SHOW OF THE CORNISH RIVIERA.
To be held April 19th and 20th.
To be opened by their Royal Highnesses Prince and
Princess Alexander of Teck.
First-class Band and Programme.
Free accommodation to the Trade.
Schedules and full particulars,
R. E. GILL,
Hon. Secretary,
Falmouth.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Liverpool Spring Show.

The spring show of the Liverpool Horticultural Association has for a long period ranked among the best of the early exhibitions in England, and the twenty-third of the series, which opened on April 5 for two days, may certainly be described as well maintaining the association's reputation. The Corn Exchange is a roomy building, which lends itself well to the effective arrangement of floral exhibits, and on Wednesday the scene was one of exquisite charm. In addition to spring-flowering bulbs, there were several other features that are lacking at some early shows, and consequently everybody's tastes were admirably catered for.

HYACINTHS

were shown in large numbers, and the quality was good throughout. The best twelve, distinct, singles, were staged by Mr. J. Nisbet, gardener to Miss Robinson, Holmfield, Aigburth. Queen of Pinks, King of Blues, City of Haarlem, and Queen of Blues were tall, shapely spikes, staged in nice condition. Mr. Thos. Hitchman, gardener to Arthur Earle, Esq., J.P., Childwall Lodge, Wavertree, took second, his flowers being a trifle smaller, but fresh and good. Third, Mr. A. Lewis, gardener to T. Von Heyder, Esq., Stone House, Allerton. Eight entries. Six singles brought nine entries, Mr. Nisbet again scoring, his plant of Menelik, one of the darkest varieties, carrying a grand spike; second went to Mr. J. V. Thompson, gardener to Mrs. D. P. Sinclair, Rivelm, Princes Park, Liverpool; Mr. Thos. Hitchman taking third.

Some good plants were staged in the class for six pots, three bulbs in each, five exhibitors competing. Mr. E. R. Finch, gardener to W. J. Lockett, Esq., Grassendale, led. His three bulbs of Yellow Hammer carried five good spikes, La Victoria and Correggio also being good. Mr. Nisbet followed, one of his pots carrying three spikes to each bulb, the spikes being necessarily rather thin; third prize went to Mr. John McColl, gardener to J. W. Hughes, Esq., New Heys, Allerton. For three pans of not more than ten bulbs each, Mr. Thos. Hitchman scored, second going to Mr. Geo. Osborne, gardener to Drs. Tisdall and Ingall, Tue Brook Villa, Tue Brook, and Mr. A. Lewis coming third.

TULIPS.

Twelve pots, singles, brought four entries, Mr. J. V. Thompson leading with a bright lot of well-grown flowers; second went to Mr. Jas. Williams, gardener to C. J. Proctor, Esq., J.P., Boscobel, Oxton; and third to Mr. E. R. Finch. There was a strong entry for six pots, singles, and here Mr. James Williams was the leader; Grace Darling, Couleur Cardinal, and Sarah Bernhardt were finely shown. Mr. E. Wharton, gardener to John Findlay, Esq., Mairscourt, Sefton Park, was second, with smaller flowers; Mr. Thos. Hitchman third. Six pots, doubles, made a good display. The winning lot, staged by Mr. Jas. Williams, being of great size and substance. Mr. J. V. Thompson made a good second, and Mr. E. R. Finch third (nine entries).

DAFFODILS.

Six pots, in not less than three varieties, found Mr. Nisbet to the fore, his varieties being Mdme. de Graaff, Glory of Leiden, Victoria, Emperor, and two pots of Mdme. Plemp. Mr. Geo. Osborne followed with Mrs. J. B. M. Camm and Empress, as well as four of Mr. Nisbet's varieties.

Collections of cut daffodils were not a great feature, there being no entry for 25 varieties, and only one for twelve, this being staged by Mr. Geo. Osborne, who received first prize. Four entries for a basket of cut daffodils, arranged with suitable foliage, were tastefully staged, the winner being Mr. E. Wharton. His basket was of massive design, and flowers were liberally used without undue crowding. Croton leaves and Asparagus plumosus constituted the foliage. Mr. Jas. Williams was second, and Mr. W. H. Roberts, gardener to F. Dixon-Nuttall, Esq., Nutgrove Hall, St. Helens, third.

MISCELLANEOUS.

In the miscellaneous section some splendid specimen plants were shown. The rhododendrons, azaleas, roses, lilacs, and trained clematis producing glorious masses of bright and cheerful colours. Specimen orchids were also remarkably well shown, and one of the most prominent and successful exhibitors of these subjects was Mr. G. Eaton, gardener to W. Ted, Esq., Dry Grange, Allerton. Among his wins were firsts for one and two specimen orchids, with immense plants of Cymbidium Lowianum; firsts also for three rhododendrons, four azaleas, four cinerarias, one rhododendron, and one greenhouse plant—Imantophyllum miniatum. Mr. E. R. Finch took firsts for three greenhouse azaleas, six forced hardy plants, four hardy plants, and one hardy azalea.

Three splendid entries for six pots of amaryllis, distinct, were forthcoming in the class provided by Messrs. R. P. Ker and Sons. The first prize was awarded Mr. W. Hignett, gardener to C. W. Carver, Esq., Woodbourne, West Derby. Mr. E. R. Finch second, and Mr. Thos. Rigg, gardener to Miss McKean, Wavertree Lodge, Wavertree, third.

Mr. W. Hignett took firsts for one specimen dendrobium and for two specimen orchids, distinct, showing some very large plants of D. nobile and D. Ainsworthi, which carried an immense quantity of flowers. Mr. Eaton scored again for a group of twelve Cineraria stellata, second prize going to Mr. D. McKelvie, gardener to John Stone, Esq., J.P., Blackdon Roby; Mr. F. C. Keightley, gardener to Mrs. Duncan Prizett, Grassendale, third. Mr. F. Atkin, gardener to F. W. Wright, Esq., Mossley Vale House, Mossley Hill, scored for six Primula sinensis in the class provided by Messrs. Sutton and Sons, second going to Mr. Thomas Hitchman, and third to Mr. E. R. Finch. Mr. Atkin again scored for six table plants, showing nice serviceable crotons, pandanus, and dracænas.

A dinner table decorated with flowers found Mr. J. Armitstead, gardener to Mrs. T. A. Vlasto, Bounevaine, Sefton Park, the leader of three entries. His table was treated with red roses and lily of the valley. The second prize table was decorated with carnation Mrs. Burnett, the exhibitor being Miss Newsham, Old Hall, Aughton. Mr. Jas. Williams came third, using daffodils and trails of Asparagus Sprengeri.

NON-COMPETITIVE.

The show was well supported by trade exhibitors, whose exhibits added both variety and interest to the display. Messrs. Mansell and Hatcher, Ltd., Rawdon, Yorks, brought a group of choice orchids, which, arranged in a tasteful manner, constituted a feature of the show. Many beautiful odontoglossums occupied the centre of the stage, with large, well-flowered dendrobiums at either end. Cattleyas, cypripediums, and a number of particularly good examples of the bright Oncidium concolor made up a splendid exhibit. The magnificent amaryllis staged by Messrs. R. P. Ker and Sons, Aigburth Nurseries, Liverpool, were remarkable alike for variety of colour and beauty of form. The intensity of the crimsons and scarlets was the more marked in consequence of the many delicate tints of other varieties, several quite new shades of rose-pink and orange being included among them. Messrs. Ker's group was well set off by a background of palms, ferns, etc., and some forced azaleas and other flowering shrubs were also staged.

Perpetual carnations from Messrs. W. Cutbush and Son, Highgate Nurseries, London, were tastefully arranged with trails of Asparagus Sprengeri as a set-off. Pink Delight, Lady C. Waring, Glendale, and Marmion stood out conspicuously as a few of the most distinct varieties. An exhibit of choice daffodils was staged by Messrs. Barr and Sons, Covent Garden, London. Mermaid, King Alfred, Sunrise, and Lord Kitchener were worthy of note.

Exhibits of alpine plants were present in considerable numbers, and many choice plants were shown. Messrs. Bees, Ltd. Liverpool, occupied about 100 square feet of tabling with an interesting exhibit of rock plants, among which primulas predominated. Their recent introductions from China were well represented, P. Forresti, P. pulverulenta, and the quaint little P. muscarioides being supported by many older favourites. P. malacoides and the variety alba were staged finely; and among other good things exhibited was Rhododendron racemosum, the plants being smothered in bloom. Messrs. Bakers, Wolverhampton, brought some choice little primulas and other alpine plants, which they placed in fibre and moss, making a bed of beautiful flowers. Lychnis alpina, Sanguinaria canadensis, Incarvillea grandiflora, and Cypripedium spectabile were nicely shown; and the rich purple-blue Viola gracilis was another choice item in this exhibit.

The Tully Nurseries, Kildare, Ireland, made a remarkably fine display of alpines, including such gems as Morisia hypogæa, Shortia galacifolia, Saxifraga oppositifolia, and many choice primulas. A plant of a new hybrid primula, named Mrs. Hall Walker, was staged, and may be described as a rich lavender flower, borne on erect stems above prettily-toothed glaucous foliage. It is certainly a distinct plant.

A group of azaleas, rhododendrons, and lilacs, put up by Mr. Wm. Rowlands, Childwall Nurseries, Wavertree, provided a fine bit of colour just beside the entrance door. Another bright exhibit of azaleas, deutzias, etc., came from Messrs. Thos. Davies and Co., Wavertree. The Liverpool Orchid and Nursery Co., Lim., Gateacre, put up a small group of odontoglossums, oncidiums, Læliocatleyas, and other orchids. Daffodils and tulips were admirably staged by Messrs. Hogg and Robertson, Lim., Dublin, who also had some beautiful flowers of their excellent strain of St. Brigid anemones.

MEDALS.

Gold.—Messrs. R. P. Ker and Sons, Liverpool; Messrs. Mansell and Hatcher, Lim., Rawdon; Messrs. W. Cutbush and Son, London; the Tully Nursery Co., Kildare.

Silver. — Messrs. Bees, Lim., Liverpool; Mr. Henry Middlehurst, Liverpool; Messrs. Barr and Sons, London; Mr. W. Rowlands, Liverpool; The Liverpool Orchid Co., Lim.; Messrs. Thos. Davies and Co., Liverpool; Messrs. Bakers, Wolverhampton; Mr. C. A. Young, West Derby; Messrs. Hogg and Robertson, Lim., Dublin; A. W. Carver, Esq., West Derby.

Redhill and Reigate Gardeners' Association.

This association held its fortnightly meeting on March 21 in the Penrhyn Hall, with Mr. W. P. Bound in the chair. Mr. J. Wright, V.M.H., Horticultural Instructor to the Surrey County Council, was the lecturer for the evening, his subject being "Hardy Fruit." There was a large gathering of members, and the lecture, which was of high educational value, received the closest attention from the large audience. A hearty vote of thanks was accorded Mr. Wright at the close of his lecture.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, MARCH 28.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair), Dr. Voelcker, Canon Fowler, and Messrs. Pearson, Chapman, Worsley, Hales, Holmes, Bennet-Poë, Odell, Fraser, Arkwright, Hill, Elwes, Rolfe, and Chittenden (hon. sec.).

JASMINUM PRIMULINUM DISEASED.—Mr. Odell showed flowering shoots of Jasminum primulinum with brown patches here and there upon the stems, and withered foliage above them. The cause of the presence of these brown patches was the attack of the fungus Botrytis cinerea, a fungus which, while usually saprophytic, is capable of attacking living tissues and causing death, especially when the growths are sappy.

PRIMULA WITH FOLIOSE CALYX.—Mr. J. Fraser showed a flower with leafy calyx segments, which was, perhaps, a common primrose, but possibly a cowslip, similar to a dried specimen which had come from Wincanton, which he also showed.

CROCUS SPORT.—Mr. Bowles showed a deep purple sport of the Crocus President, from Mr. Jacob's garden at Whitchurch. One corm had produced three flowers, the two lateral ones bearing typical President, with colour and striping characteristic of that variety, the middle one being the sport in question.

PYRONIA x JOHN SEDEN.—Messrs. Veitch sent a fruit of this interesting cross, which Mr. Worsley took for further examination.

RHODODENDRON FARGESI.—A flowering shoot of this new Chinese rhododendron came from Mr. P. D. Williams, of Lanarth, Cornwall.

FUNGI PARASITIC ON INSECTS.—The Secretary, on behalf of Mr. W. A. Voss, showed a number of specimens of white fly (Aleyrodes sp.) and scab insects attacked by parasitic fungi, sent by Dr. Berger, of the U.S.A. Experiment Station, Florida. In Florida, considerable success has been achieved in dealing with insect attacks by spraying trees with water containing spores of fungi parasitic upon the insects. The fungi exhibited were Ascheronia flavocitrina on citrus white fly, A. aleurodes on white fly, Aegerita Webberi on white fly, Sphærostilbe coccophila on Orange scale, and on San Josè scale, Verticillum heterocladium on white fly and scale, Myriangium duryi on San Josè scale, and Ophionectria coccicola on San Josè scale.

BOTANICAL CERTIFICATE, ETC.—The discussion upon Mr. Worsley's motion that a new certificate was desirable was continued, but the committee were of opinion that the existing Botanical Certificate and the Certificate of Appreciation covered all the purposes, at present, for which such awards were required. A resolution was therefore sent to the council suggesting the desirability of restricting the recommendation of the award of the Botanical Certificate to the Scientific Committee.

Beckenham Horticultural Society.

The concluding lecture of the winter session, 1910-11, was given by Mr. Alex. Dean, V.M.H., on the 31st ult., his subject being "Elementary Landscape Gardening." Mr. Francis Hooper, vice-president, occupied the chair, and there was a good attendance. The lecturer, though not posing as a landscape gardener in a strict sense, delighted his audience by the way he handled his subject. The various styles, from the "Tudor," with its clipped yews, topiary work, etc.; the Dutch, Italian, and French parterre, were passed under review, and their chief points dilated on briefly. Following this, the various items that would require consideration from the gardener laying out his place, i.e., draining, lawn making, rockwork, water, roads and paths, planting trees and shrubs, etc., all these were discussed, and in each case a deal of instruction was given on how to carry out the work, sound cultural hints being added. A very hearty vote of thinks was accorded Mr. Dean for so kindly coming to Beckenham, though in his 80th year.

Southampton Gardeners' Society.

The monthly meeting of this society was held on Friday, March 31, in the Highfield Church Institute. Mr. B. A. Andrews was in the chair, and there was a good attendance of members.

Mr. O. Nicklen, of Ashton Lodge Gardens, Bassett, read an interesting and instructive paper on the cultivation of the rose for exhibition and decorative purposes. His remarks were followed with close attention, and, after an excellent discussion on the several points raised in the paper, and a number of questions answered, a hearty vote of thanks to Mr. O. Nicklen, proposed by the Hon. Secretary, and seconded by Mr. A. Greenaway, was carried with acclamation.

Eight new members were admitted, and the next meeting will be held on April 28.

Bristol and District Gardeners' Association.

The usual fortnightly meeting was held on March 30 at St. John's Parish Rooms, Mr. Hayball presided over a good attendance. A paper on "Orchids" was read by Mr. Cave, gardener to Dr. Eager, Northwoods. The lecturer said in no department of horticulture has such progress been made in recent years as with orchids. In former years there was often great loss of valuable plants through ignorance. But since cultivators have studied the requirements of the numerous species and varieties, and treated them under proper conditions, much greater success had been achieved, and now their cultivation is considered to be fairly easy. Mr. Cave said that moisture is the most important factor in orchid cultivation. He recommended a compost of equal parts osmunda fibre and sphagnum moss for most kinds, with the addition of loam for cypripediums. In the case of newly-imported plants it was important to see that the last growth is perfectly sound, and be very careful in watering until making new growth, using nothing but rain water for all purposes. A good discussion followed, after which a hearty vote of thanks was accorded Mr. Cave.

For two pots of mignonette Mr. Candy was first, Mr. Spry second, Mr. Shelton third. Mr. Springham gained five points, and Mr. Woodward three.

Elstree and Boreham Wood Horticultural Society.

On Tuesday, March 14, a large audience assembled in the Church Room, Elstree, to hear Mr. Andrew Ireland, of Messrs. Dobbie and Co., lecture on "Sweet Peas." Needless to say that the remarks made by such an authority as Mr. Ireland were brimful of interest, and of a thoroughly practical nature. The lecturer dealt with cultural detail, and fully described the best methods, both in relation to autumn and spring sowing, preparation of the ground, planting, and subsequent treatment, and he afterwards dealt with the newer varieties. Several questions were afterwards asked, and satisfactorily replied to, and a hearty vote of thanks was accorded Mr. Ireland for his kindness in entertaining them that evening.

On Wednesday, March 22, the spring show took place, and there was a brisk competition for prizes for pot hyacinths, offered by the society to school children and others. A good show resulted. The president, the Hon. V. Gibbs (gardener, Mr. E. Beckett, V.M.H.), staged the exhibits with which he won prizes at Vincent Square, and these were greatly admired. A general discussion took place afterwards, the members handing in questions for debate. Votes of thanks were accorded those who contributed towards the success of the meeting.

Broughty Ferry Horticultural Association.

The ordinary monthly meeting was held in "The British Workman" on March 21, when Mr. Andrew McAntkie, Ruthven Gardens, Meigle, submitted an essay on "The Pelargonium." After dealing with the subject in a general way, the essayist entered into the cultivation of bedding pelargoniums, and gave a list of the best varieties for this purpose. Passing on to deal with pot plants for the greenhouse and conservatory, he gave exhaustive details on their cultivation and treatment to ensure a continuous supply of flowering plants throughout the year. Damp was the worst enemy to winter-flowering plants, and a bracing atmosphere was necessary to counteract the evil.

In a subsequent discussion many interesting points were debated, after which the essayist was cordially thanked.

Among a number of exhibits on the table was a magnificent specimen of Cyclamen persicum giganteum album with about 500 flowers, fully developed, and numerous buds pushing up. This plant was grown and shown by Mr. John Bell, Corona Gardens, who has for the past six years been breaking his own records in cyclamen growing. The plant under notice was a three-year-old corm, growing in an eight-inch pot, and was admitted by all the members present to be the finest specimen they had ever seen. On the motion of Mr. Wm. Grant, Mr. Bell and the other exhibitors received the thanks of the meeting, and a like compliment to the president, Mr. James Bethel, closed the proceedings.

NOTES OF OBSERVATION.

◆

Single-flowered Camellias.—As with many other classes of plants, camellias whose blossoms are single, or at most semi-double, are appreciated much more than they formerly were. Compared with the formal blossoms of the double kinds, these single varieties are light and elegant in appearance, the central ring of yellow stamens forming in some of them a very noticeable feature. They are certainly very handsome in the greenhouse or conservatory, and as outdoor shrubs are far hardier than they are generally considered to be. Of the single-flowered forms I particularly like Alba simplex, pure white; Jupiter, rosy-red; Mercury, rich crimson; Minerva, deep rose; and Waltham Glory, very bright red.—W. T.

Hovea Celsi.—The comparative few whose experience goes back to the time when large specimen plants of various hard-wooded subjects formed a prominent feature of many exhibitions, will recognise in this an old-time favourite. It is an Australian member of the order Leguminosæ, and forms a loose-growing plant somewhat after the manner of chorizemas. The slender shoots are clothed for some distance with ovate deep green leaves, and studded for a considerable portion of their length with dense clusters of rich purplish blue flowers that from their distinct tint at once attract attention. Though generally known as above, the name of Hovea elliptica is now by our botanical authorities applied to it.—W. T.

Indian Azaleas.—One cannot fail to be struck with the change that has, within the last twenty years or so, been brought about in the generally grown varieties of the Indian azalea. At one time the varieties of a deep rose colour, often with a magenta shading, were largely grown, but now the most popular of the coloured kinds are those of a clear rose or salmon pink hue, with a light margin to the petals, and those in which the flowers are of a clear red or scarlet tint. White-flowered varieties were always and still are very popular. That small-flowered ruby-red variety, Hexe, a comparative new comer, is now grown in immense numbers in the form of little bushy plants. Another, Charles Encke, is also grown in the same way to a limited extent. The flowers of this are pink and white.—W. T.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

FLOWER BEDS.—E. P., Notts: The effect you are able to produce will depend very largely upon the size of the plants available. For the round beds use tall plants of Madame Crousse pelargonium placed thinly over a groundwork of white violas. The latter should also form a broad band round the pelargoniums, with dot plants of the salmon-pink dianthus among them. In the central bed associate the heliotrope, Calceolaria amplexicaulis, and the white and yellow antirrhinums down the centre; margin with bronze-leaved pelargoniums kept quite dwarf. The selection of plants at command is not of the best, therefore, as it is essential to secure a display as quickly as possible, you had better carpet the outer beds with yellow and mauve violas, make two circular groups of crimson pelargonium in each bed, round a central tall Calceolaria amplexicaulis, and fill in the intervening spaces with the pentstemons and antirrhinums planted thinly, so as to allow them full development. As an alternative the central beds might have the silver-leaved pelargoniums under the tall Madame Crousse, and a bordering of lobelia or Dactylis glomerata.

YOUNG GARDENERS.—C. W., Prittlewell: We imagine the address was not in manuscript, and our correspondent sent us a brief epitome of what was said. We will, however, see what we can do in the matter.

GARDENERS' ADMISSION TO OLYMPIA SHOW.—J. J., Poole: The Royal Horticultural Society's arrangements allow any bona fide working gardener, who is also a member of an affiliated society, to obtain one 2s. 6d. non-transferable ticket admitting to the Olympia Show on Wednesday, July 5, for 1s., on application to the secretary of his local society at least ten days before the show. In forwarding the member's application the local secretary must give the applicant's full name, and also certify that he is both a member of his society and also a bona fide gardener working in the locality. A large stamped and directed envelope should be enclosed with postal order in every case.

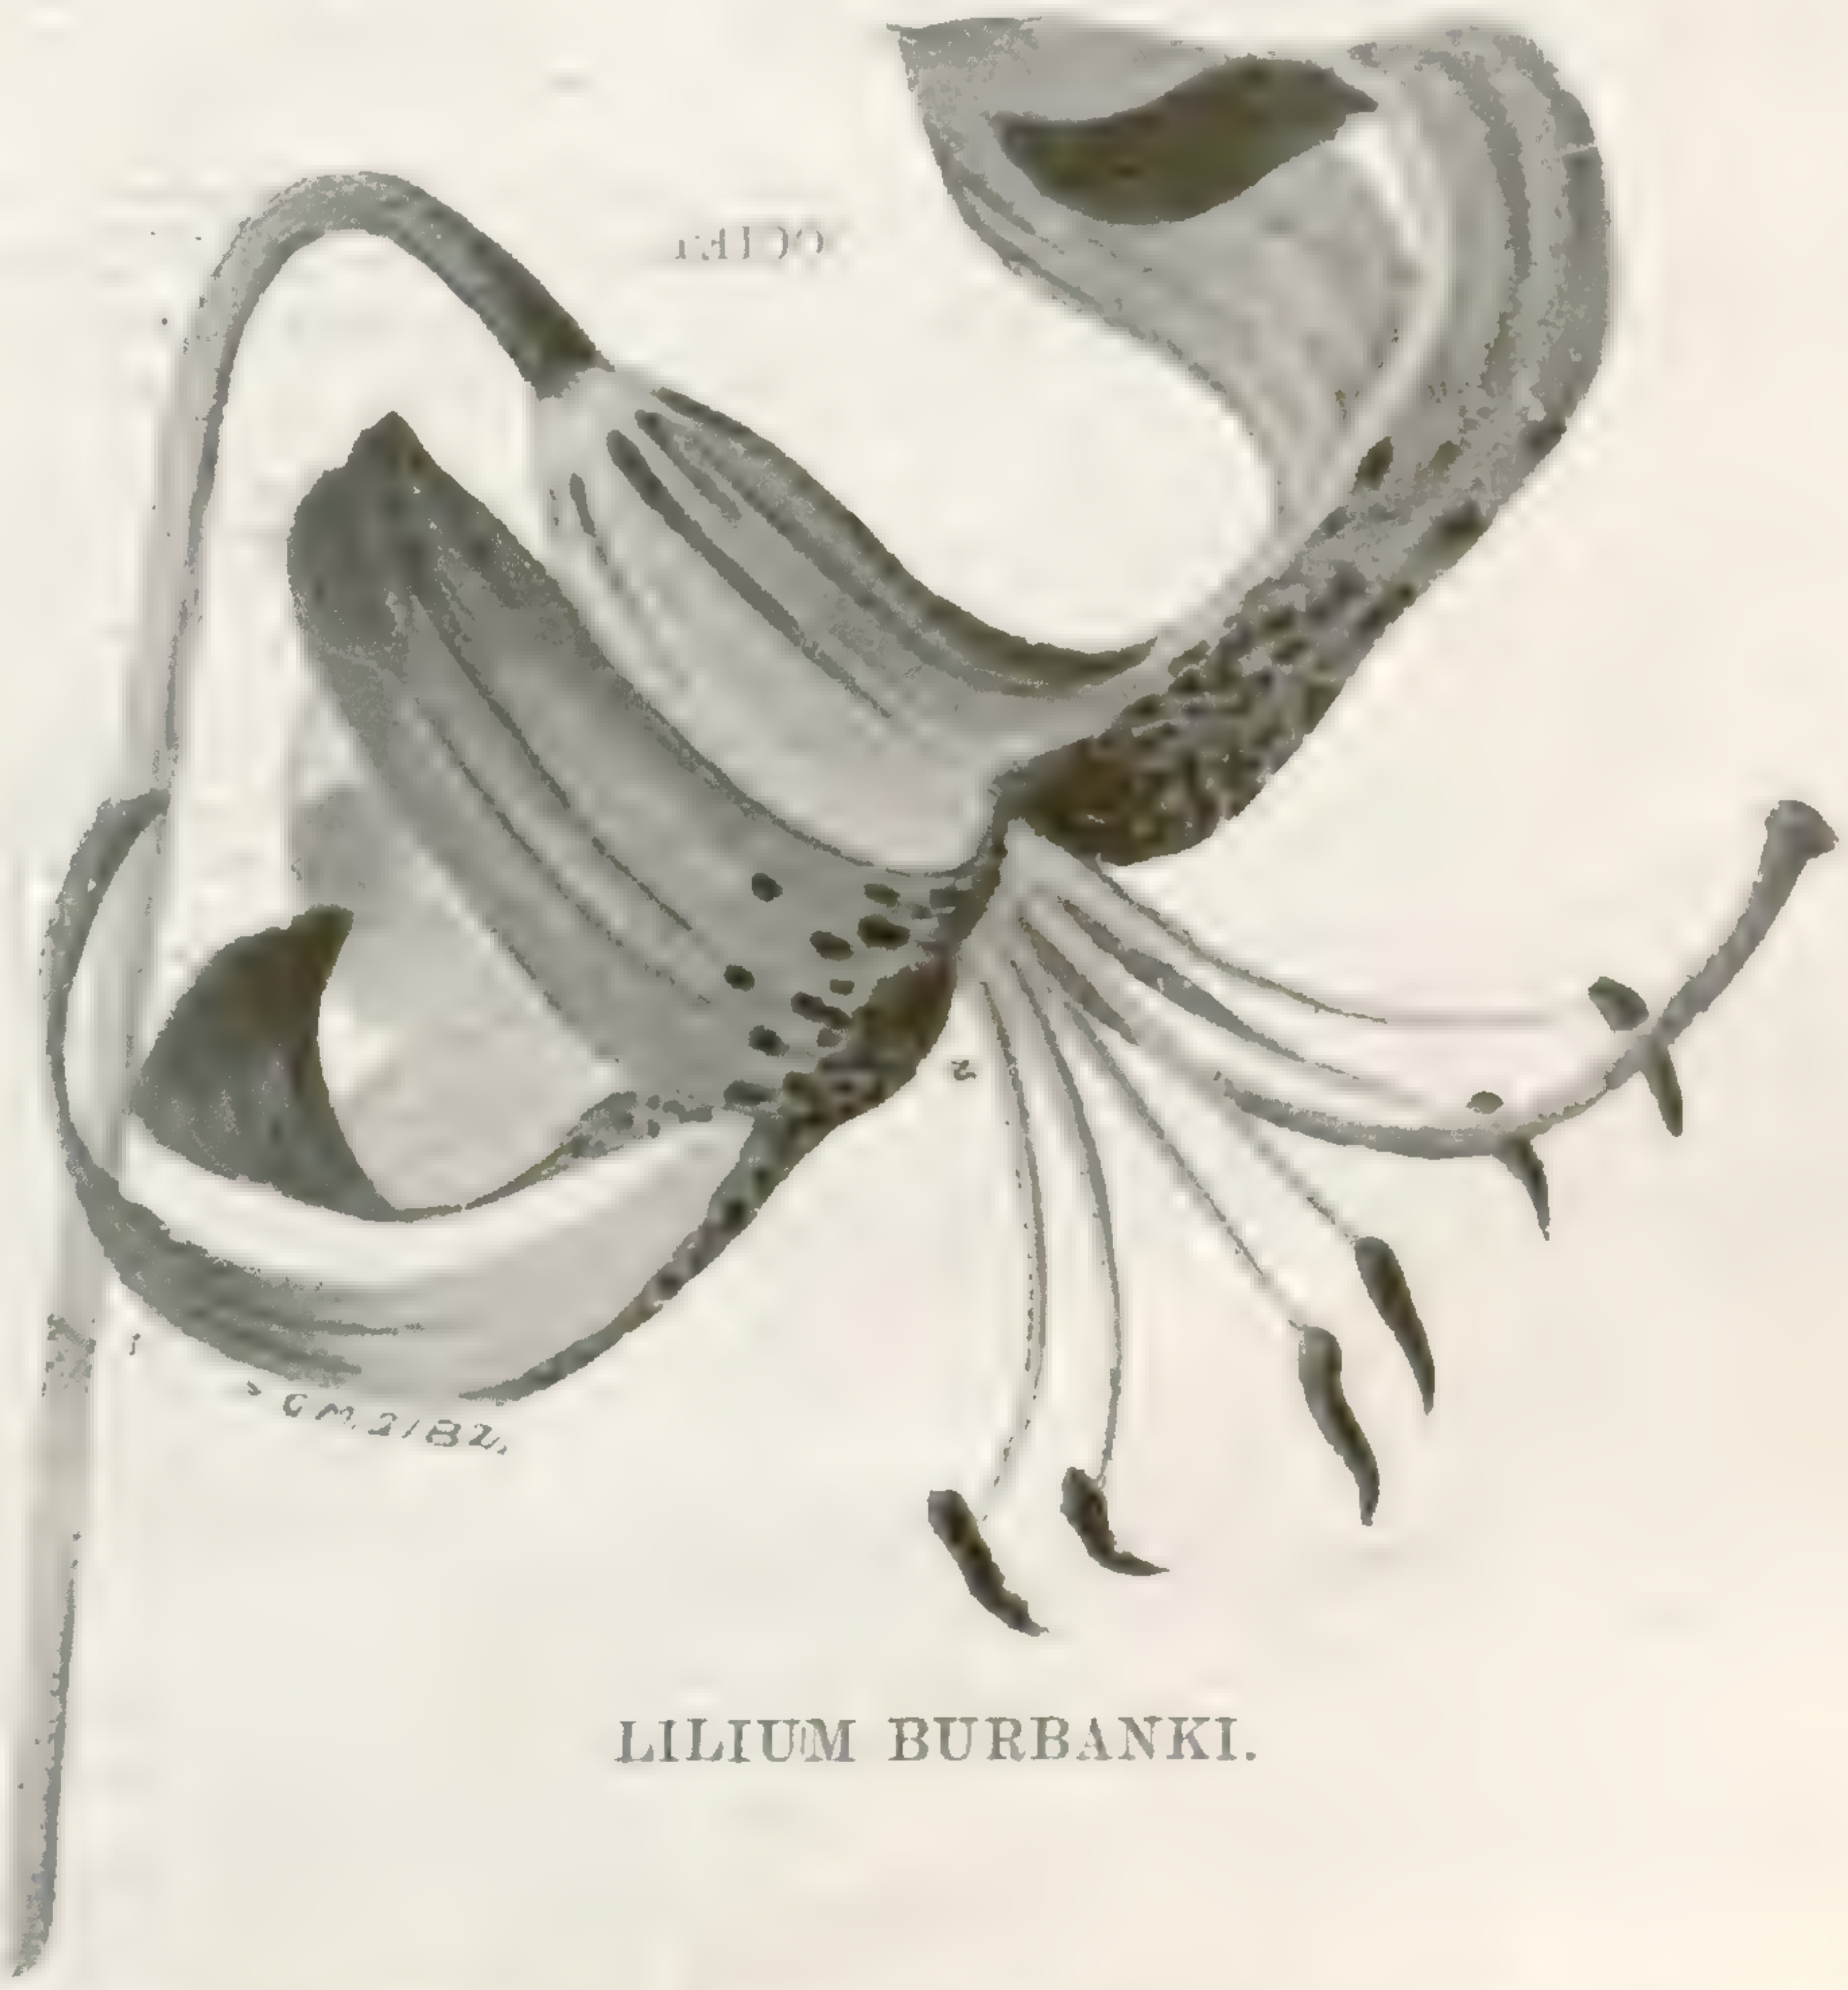
PROPAGATION OF EPIGÆA REPENS.—A. R. S., Sidcup: This low-growing, fragrant-flowered shrub is best propagated in spring by means of cuttings of the previous season's growth, placed in sandy, peaty soil, and put in gentle heat. When rooted the cuttings should be potted singly, and presently placed in a close frame. Ventilation should be given as the plants become established, so that by the autumn the best specimens may be planted out, the smaller ones being given the protection of a cold frame until the spring. Seeds germinate very slowly, but they also offer a means of increase, while division of the tufted growths in autumn, or the layering of the largest branches afford other means of propagation.

HARDY HIBISCUS.—L. A., Ivybridge: Hibiscus syriacus and its numerous varieties, single and double flowered, and ranging from pure white to deepest blue in floral colouring, are among the most popular of flowering shrubs in the South-Western Counties, and they form the most attractive group belonging to the hardy section of this genus. H. militaris, H. Moscheutos, H. palustris, and H. roseus are all more or less hardy; while H. Manihot and H. Trionum may be treated as half-hardy annuals, and raised in heat in early spring.

OURISIA COCCINEA.—T. B. C., Mitcheldean: This charming plant is the best-known member of a genus of about eighteen species. It is a native of the Chilian Andes, and, though it loves a light position in the rock-garden, full exposure to sun and wind does not suit it at all—indeed, a hot, dry place frequently proves fatal to it. A sheltered position, facing west or north-west, with ample moisture and yet a well-drained soil, will prove suitable. Stones should be placed close up to and round the plants, and these will soon be hidden by the trailing growths and a profusion of bright scarlet flowers.

COMPOST FOR THUNIAS.—C. M., Wakefield: For specimen thunias the pots should be drained one-third of their depth, and the compost used as rooting medium should be made up of equal parts of fibrous peat, turfy loam, and chopped sphagnum, with a sufficiency of finely-broken crocks and sand to keep the whole porous. Some people add a little old flaky manure to the compost, but others prefer not to do so, and give weak liquid manure when the plants are well established and growing and rooting freely.

LILIUM BURBANKI.—A. T. N., Stonehouse: The title of Lilium Burbanki has been given to a group of seedlings of mixed parentage, the species involved being L. pardalinum, L. Washingtonianum, L. Humboldti, and L. Parryi, possibly others also. It will thus be understood that the lily flowers vary somewhat in colour; they are all elegant and free flowering, and the colour is usually orange, shaded with crimson, and marked with chocolate. The petals are reflexed, and the hybrid belongs to the Martagon group. Some of the finer forms have been selected, and propagated by British specialists, and these are desirable garden plants. The flower stems rise four to six feet high, and the blooms expand during July. L. Burbanki grows well when there is ample moisture and good drainage; peat or leaf-soil should form the major part of their root run, and the site should be chosen with regard to shelter from keen drying winds.



LILIUM BURBANKI.

SILVER-LEAF IN PEACHES.—A. S., Lyndhurst: It is only quite recently that investigators have made any real progress in their efforts to deal effectively with the dreaded silver-leaf disease. So far it has only been possible to decide the cause of the trouble, and we must still wait for information concerning the methods to be adopted for staying or curing the disease. At present no cure is known. If only a branch or two are affected, cut these back to a main stem; if the trees are very badly affected they should be removed at the end of the fruiting season, and new trees be planted in the renewed border as early as possible in the autumn.

ANNUAL AND BIENNIAL PLANTS.

By A. E. Speer, F.R.H.S. (John Murray, 50a, Albemarle Street, London.) Price, 7s. 6d. net.

Within a comparatively recent period there has been a material increase in the literature devoted to annual and biennial plants of value for the embellishment of the flower garden, and if we have not as yet had the ideal book on these subjects, the cultivator has had placed at his command an immense amount of information relating to them. It appears to have been an irresistible temptation to the authors of books on annuals to include a considerable number of plants that are strictly perennial in growth. This is done with a view to include all the more noteworthy plants that can, under the more modern methods of culture, be grown from seed to a suitable size for planting out by the time beds and borders are ready for the reception of their summer occupants. That they should be included is, in some respects, a great advantage to the cultivator in need of information, and their inclusion would merit unqualified praise were the authors to arrange the several classes under their respective headings, or clearly indicate in some other way the class to which each species and variety belongs. We are induced to make special reference to this point because annuals and biennials are rapidly increasing in popularity, and prizes are offered for them at a large number of exhibitions in the course of the summer, and many are the disqualifications owing to the exhibitors including perennials.

The book before us is not free from this drawback, but it is so thoroughly good in all that relates to the selection and cultivation of the plants that come within its scope, that we have no hesitation in heartily congratulating the author on what he has accomplished, a by no means easy task, and recommending our readers to give it a prominent position among their books on the garden and its management. The large number of plants included in its pages have been selected with judgment, the descriptions are clear, and the cultural details are stated briefly and in such manner as to leave no doubt in the mind of the reader as to the course he should take in the raising and preparation of stocks of plants with which he is but imperfectly acquainted. The book is freely illustrated with coloured plates and photographic reproductions.

OBITUARY.

◆

MR. B. C. CHAMBERS.

Mr. B. Coates Chambers, of Grayswood Hill, Haslemere, died, we regret to learn, at Hyeres, on March 23. The deceased gentleman was an enthusiastic gardener, and during his thirty years' residence at Haslemere he formed one of the most interesting of gardens to be found in the kingdom, filling it with the choicest of trees, shrubs, and flowers, and selecting the right positions for these with, apparently, unfailing accuracy.

MR. JOHN MUIR.

"Muir of Margham" was a striking personality in the horticultural world a quarter of a century ago, but during later years he retired from the exhibition arena. Mr. John Muir was a famous gardener, and for a number of years had charge of the gardens at Margham Abbey. He was a prolific writer and an acknowledged expert in all branches of horticulture. His death recently is a great loss to the horticultural world.

Debregeasia velutina.—At one of the January meetings of the Royal Horticultural Society a group of this uncommon plant was shown. It was, I venture to think, quite unknown to the majority of the visitors, and attracted a good share of attention. It belongs to the mulberry section of the Nettle family, and forms a loose-growing shrub, whose long shoots are clothed with lanceolate leaves, about six inches long, and soft in texture. The flowers, borne in clusters from every joint, even on the older wood from whence the leaves have dropped, are inconspicuous, but are succeeded by softish fruits, which, when ripe, are the size of peas, and of a bright orange colour. This debregeasia is a native of India, and was introduced about fifteen years ago.—W. T.

There is no better guide to the kitchen garden than VEGETABLES AND THEIR CULTIVATION, by T. W. Sanders. It is a complete treatise on the general management of the garden, and the successful culture of vegetables, saladings, and herbs for home use. Price 5s. net, by post, in box 5s. 6d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

FORTHCOMING ENGAGEMENTS.

MONDAY, April 10.—United Horticultural Benefit and Provident Society, committee meeting.

TUESDAY, April 11.—Royal Horticultural Society; Daffodil Committee meets at 11.30, Fruit, Floral, and Orchid Committees at 12 o'clock; lecture at 3 p.m. on "The Origin and Structure of Aquatic Flowering Plants," by the Rev. Prof. G. Henslow, V.M.H.; Scientific Committee at 4 o'clock.

THURSDAY, April 13.—National Horticultural Society of France; exhibition and meeting in Paris.

WEDNESDAY, April 19.—Royal Horticultural Society of Ireland: Spring Show.

Devon Spring Flower Show, at Plymouth; two days.

THURSDAY, April 20.—Ipswich Spring Show.

TUESDAY, April 25.—Royal Horticultural Society; Daffodil Committee meets at 11.30; Fruit, Floral, and Orchid Committees at 12 o'clock; lecture at 3 p.m. on "The Tulip: Its Problems and History," by Rev. J. Jacob; Scientific Committee at 4 o'clock.

National Auricula and Primula Society's Show, in conjunction with Royal Horticultural Society.

National Rose Society; Special General Meeting. 3 p.m. Rose Conference with address by Rev. J. H. Pemberton, 5 p.m., Dinner 7 p.m., at Westminster Palace Hotel, Victoria Street, S.W.

CATALOGUES RECEIVED.

H. J. JONES' NURSERIES, LIM., RYECROFT, HITHER GREEN, LEWISHAM.—The neat red-covered catalogue before us is generally useful, but is of special interest for its descriptive lists of dahlias, pelargoniums, chrysanthemums, fuchsias, Michaelmas daisies, and sweet peas.

JAMES VEITCH AND SONS, CHELSEA.—A useful, descriptive, and priced list of dahlias, the varieties being carefully grouped in their several sections. A descriptive list of hardy water lilies is also sent.

ROBERT P. KER AND SONS, AIGBURTH NURSERY, LIVERPOOL.—A handy, illustrated catalogue of this firm's new and beautiful amaryllis or hippeastrums. Thirty-two gold medals now stand to this firm's credit for these handsome bulbous plants.

"CARRUSTICIDE."

The Best and Cheapest Remedy for Carnation Rust and other Fungoid Diseases.

A well-known Carnation Grower writes:

Dear Sir, The Nurseries, March, Cambs.

"During the 27 years I have been growing Carnations (Perpetual and American) I have tried most of the fungicides placed on the market, but yours is the best. It is a pleasure to see how "Carrusticide" catches hold of the Rust and destroys it. I should say your preparation will be extensively used when it is better known." Yours very truly,

GEO. CLARKE.

One gallon makes 25 gallons for spraying purposes —**Price 3s. per quart, 7s. 6d. per gallon.** Special quotations for larger quantities.

KELWAY'S LATEST SUCCESS.
GRAND PRIX AND GOLD MEDAL, Japan-British Exhibition, White City. Unanimous award of the International Jury to Kelway and Son for Paeonies, Delphiniums, Gladioli, Pyrethrums, etc.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

THE KELWAY ARTISTIC BORDER ensures a garden of enduring beauty from early Spring to late Autumn with a minimum of cultivation, and without the trouble of constant digging or bedding out. The plants composing the border are selected by experts, and include some of Kelway's improvements in Paeonies, Delphiniums, etc. Send dimensions of spaces to be filled, or for Kelway's "Gardens of Delight," 6d. The cost of this border is 15s. or 25s. for every 10 square yards. Carriage and package free for remittance with order.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

KELWAY'S MANUAL OF HORTICULTURE is the best of all Garden Books, 2s. post free, from KELWAY and SON, LANGPORT, SOMERSET.

NOW IS THE TIME TO PLANT KELWAY DELPHINIUMS, which have been improved almost out of recognition in the past twenty years. They produce plants ranging in height from four to eight feet, exceptionally hardy and with a rich profusion of choice blooms in all the shades of that valuable colour, blue.

Choice named varieties: 24s., 34s., and 56s. a dozen. Carriage and package free for remittance with order.

The celebrated present-day Delphiniums, and nearly all the best well-known varieties shown at exhibitions, originated in Kelway's Langport Nurseries.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

CONSERVATORIES AND WINTER GARDENS, Greenhouses, Plant Houses, Vineries, Peach and Orchard Houses, Verandahs and Porches, Garden Frames, Greenhouse Fittings, etc.; Boilers, Pipes, and Heating Apparatus of every description. Send for Illustrated Catalogue free.—BOULTON and PAUL, Lim., Norwich.

GARDEN NETTING (best tanned only).—25 yds. x 8yds.; 50 x 4yds.; 100 x 2 yds., 8s. each. 50 x 2 yds.; 25 x 4 yds.; 100 x 1 yd., 4s. each. All sizes, large or small, at 1s. 20 sq. yds. Quality guaranteed.—EVANS, 14, Beresford Rd., Lowestoft.

THE POPULARITY OF XL ALL SPECIALITIES increases every year. All gardeners proclaim that nothing equals these celebrated preparations.
XL ALL NICOTINE VAPORISING COMPOUND, the gardener's favourite Fumigant, both Liquid and Cake.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Garden Flowers.

We have for some time been advocating the development of dahlias on lines differing somewhat from those which have been followed by raisers for a considerable period, with a view to an improvement in the position which these flowers occupy, and we derive much satisfaction from the knowledge that our advocacy is accomplishing its purpose. We have urged, among other things, that in the development of the cactus dahlia an endeavour should be made, not only to improve the size and form of the flowers and evolve new shades of colour, but to increase the rigidity and length of the flower stems sufficiently to carry the blooms well above the foliage. It appears to us so obvious this should be done that it comes somewhat as a surprise to be told that owners of gardens care nothing about the cactus dahlia from the decorative point of view; that their whole interest in this important section is centered in the individual blooms. This has not been our experience, and, so far from it being so, we have been frequently assured by owners of small gardens and those in charge of large ones that they feel it a matter for regret that plants producing blooms of such exquisite form and attractive colouring should not produce them in such manner that they can be readily seen. Lest our views should be misunderstood, and there appears to be some little misapprehension upon this point, we would state in the most distinct manner that, in advocating the creation of a race of garden cactus dahlias, we do not suggest there should be any relaxation in the endeavour to improve the cactus section for exhibition purposes. We did not intend referring to this matter further for the present, but we have been reading some literature bearing on it in which views are expressed that evince a wide divergence from our own. It may be we owe their expression to what we have written, but whether that be the case or not is a matter of but little consequence. The point of interest to ourselves and our readers is the statement that, if we would increase the popularity of the dahlia it must be by means of big blooms at the exhibitions. If we would prevent the rose falling from its high estate, we must make up the rose shows with huge exhibition blooms, for the public care but little about masses of the mere "garden variety"; and so on, with the chrysanthemum, the carnation, and some other classes of flowers. Caring little about anything but big blooms, the public will not, we are assured, go to shows where they are not represented. It is surprising, with the facilities now existing for obtaining information on all that relates to the progress of horticulture that such views should be held. They find no support from the evidence available. If we glance at the history of the National Rose Society we shall find that for a considerable period the society devoted its whole attention to "exhibition" blooms, and that throughout the whole of the period it was a comparatively small body. In course of time rose lovers began to take an interest in varieties that were so vigorous in growth and free in blooming as to be of special value in beautifying the garden, and the executive very wisely provided classes for them in the schedule, and by means of literature assisted their members in making selections. For many years garden roses have formed an important feature of the society's exhibitions, and the members have increased so rapidly since the change in policy that there are now about 5,000 on the books. We thought these facts were well known to all who take an interest in horticulture, but evidently very little must be taken for granted. Another excellent example is that afforded by the National Carnation Society. For a considerable period the society devoted its efforts exclusively to "exhibition" carnations and picotees; then, with the assistance of the late Mr. Martin Smith, border varieties were brought within the scope of the society's work, and with the most gratifying results. The membership increased, the exhibitions were extended and rendered more generally attractive, and, what was of not less importance, carnation culture was enormously increased throughout the United Kingdom. The exhibitions and meetings held by the Royal Horticultural Society during the past two decades should afford some indication as to whether the predominance of big blooms or huge specimen plants is essential to their success. That they are successful should be known to all who engage in a discussion on the all important question of the public taste in floricultural matters, and it ought also to be known to them that these gatherings owe their popularity to the admirable manner in which all classes of ornamental plants and useful subjects are represented. At these meetings the finely developed chrysanthemum, dahlia, or rose receives a share of attention, but there can be no question that the most popular of all the contributions to these gatherings are the hardy border plants, of which but few are regarded as "exhibition" subjects, although they have been considerably improved; alpine plants that have undergone but little, if any modification since they

G.M. 1703.

MR. E. H. CHRISTY.

were collected on their native mountains for beautifying British gardens, and subjects that are of value for embellishing the conservatory. These are the classes of subjects that draw visitors to the Royal Horticultural Hall in such numbers as to crowd the spacious building to its utmost capacity, and they assuredly belong to gardens and plant houses generally, rather than to special cults. With such evidence as these exhibitions afford at frequently recurring intervals, it appears to us something more than surprising that anyone acquainted with what is being done in the Metropolis should fail to recognise the fact that exhibitions have two functions: one to encourage cultural skill, and the other to bring into prominence that which is of the greatest value in enhancing the interest, attractions, and usefulness of the garden; and that exhibitions which properly fulfil their mission are those which attract the flower-loving community in the largest numbers.

Mr. E. H. Christy belongs to that excellent type of business man who, working hard in the City all day, works equally hard in his garden at either end of the business hours. That he finds pleasure, recreation, and health in the pursuit of his hobby—which, of course, is gardening—is evident, for Mr. Christy is a robust enthusiast. He has a large garden at Beacons, Ingatestone, and here he cultivates many things well. It is, however, as a sweet pea expert that he is most widely known, and not only is he a capable grower, but he takes a keen interest in the National Sweet Pea Society, is on the General Committee, and has acted on both the Executive and Floral Committees of that body. In the district in which he lives, Mr. Christy takes an interest in local horticulture, and though the office entails late hours, a railway journey, and a long walk afterwards, he has for some time been president of the Chelmsford Gardeners' Association, and it is rarely he misses any of its meetings held in the County Laboratories.

Damage to the Jersey Potato Crop.—In our issue of the 8th inst. we briefly stated that the Jersey potato crop had been seriously injured by a severe frost on the previous Wednesday. We hoped at the time the injury done was less than suggested by our correspondent, but subsequent communications show that the loss inflicted upon the growers was even greater than was at first feared. The earliest portions of the crop would have been ready for lifting during the next two or three weeks, and as these are by far the most profitable, it will not be difficult to have some idea of the loss that has been inflicted when we state that the haulm was cut to the ground. Instead of potatoes being sent to the English markets early in May, the month will be far advanced before any considerable quantity can be dispatched, and the period during which high prices are usually obtained will be missed. It is more than a quarter of a century since so heavy a loss has been inflicted upon the Jersey growers.

Photographs of Garden Scenes, etc.—Within the next few weeks the garden will afford abundant opportunities for those who have a practical acquaintance with the art of photography to display their taste and skill in the production of pictures of interesting garden scenes of the most varied character. We suggest that these opportunities should be taken advantage of more fully than has yet been the case, and at the same time we would remind our readers that we shall be pleased to see the results of their skill. We have for a long time past reminded our readers that we shall be obliged by their submitting to us photographs of interesting subjects associated with horticulture, and we give greater prominence to the expression of our desire with the hope that those who have attractive gardens and are skilled in photography will afford other readers an opportunity of participating in some degree in the pleasure tastefully-arranged gardens are so well able to give. We are, of course, prepared to pay for such photographs as we use, and as it is quite impossible to maintain the high standard of our illustrations unless the photographs are good, it is essential that those sent should be of high quality. They should be full of detail, and be bright and clear. Many photographs that reach us are unsatisfactory owing to the over or under exposure of the negatives, and we strongly advise amateur photographers to invariably use a light meter. These meters are inexpensive and easy to use, and soon save their cost in plates, besides enabling the photographer to avoid much vexation. The photographs should be sent addressed to "The Editor of the Gardeners' Magazine, Endsleigh, Priory Park, Kew."

Shrewsbury Floral Fete.—The financial results of the Shrewsbury Floral Fête in August last were not less satisfactory than the horticultural features as recorded in these pages at the time. According to the recently issued balance-sheet, the receipts for admission amounted to £3,105 15s. 1d., as compared with £2,689 6s. in 1909, and the income from all sources was £5,756 15s. 3d., against £5,245 18s. 7d. in the year previous.

Plague of Nematodes in the Midlands.—At the recent annual meeting of the Association of Economic Biologists at Birmingham Mr. Walter E. Collinge read a paper on "The Plague of Nematodes in the Midland and Other Counties." In his opening remarks, he said that the plague of these worms was crippling the growers of almost every farm and garden crop. No plague of such a magnitude had hitherto been known, and it was not confined to this country. The groups of worms which were causing the damage were popularly known as eelworms and white worms, and the knowledge of their life history and bionomics was scanty. He believed that much of the trouble was owing to the failure to burn diseased crops. The presence of weeds, particularly nettles and thistles, along hedgesides offered a particularly favourable breeding ground for eelworms. He had found eelworms equally plentiful in wet and sticky, dry, light, and heavy soils. The white worms flourished where the soil was poor. He recommended the application of basic slag and ground unslaked lime. In some cases soil fumigants had given good results. He appealed to those who had the direction of students at the Universities and elsewhere to bear in mind what extremely valuable service they would be rendering if they would set them to work out the structure and bionomics of these and allied pests.

British Horticultural Traders in America.—The British horticulturists who have been on a visit to the United States arrived safely, and received a warm welcome from their friends on the other side of the Atlantic. Arriving at New York on March 17, they proceeded to Philadelphia, and returned on the following day for the annual banquet of the New York Floral Club. Returning to Philadelphia they visited Baltimore and Washington and then proceeded to Richmond, Indiana, where they were received and entertained by Mr. E. G. Hill. Thence they went to Chicago, arriving there on March 24, when they were shown round the city, visiting the public parks, Swift's packing plant at the stockyards, and the nurseries of Messrs. Poehlmann Brothers. On their arrival at Chicago they were met and escorted to the Hotel Sherman by representatives of the Chicago Florists' Club, who entertained them at luncheon at the South Shore Country Club and dinner in the evening at the Union restaurant. The members of the party made a three-days' stay in Chicago and on leaving that city they proceeded to the Niagara Falls, previously expressing their high appreciation of the reception that had been given them at the American cities visited. The members of the party are Mr. J. Brown, Stamford; Mr. J. S. Brunton, Burnley; Mr. E. Barker, Manchester; Mr. W. A. Cull, Lower Edmonton; Mr. C. Engelmann, Saffron Walden; Mr. J. S. Gunn, Birmingham; Mr. L. M. Graves, Harlington; Mr. G. Prickett, South Tottenham; Mr. C. Pratley, Edmonton; Mr. J. Simpson, Burnley, and Mr. S. South, Tottenham.

The National Carnation and Picotee Society has issued its schedule of prizes for the present year, and this follows pretty much on old lines. The Martin Smith Memorial Cup, won in 1910 by Mr. H. R. Taylor, and the Cartwright Challenge Cup, won during each of the last three years by Mr. Jas. Douglas, are figured, and there is a complete list of the prize winners at the 1910 exhibition. Besides the annual report for 1910, and the list of members, there is an interesting contribution on the "Standard of Excellence in the Carnation and Picotee." Mr. Leopold de Rothschild is the president of the society, and Mr. T. E. Henwood, Hamilton Road, Reading, continues to act as hon. secretary and treasurer.

A Cold Week.—In connection with the low temperature that was experienced during the week ending on the 8th inst., it can hardly fail to be of interest to mention that there have been during the past forty years, four weeks in April in which the temperature has been considerably below the average. It is of interest also that two of these weeks ended with the 8th and 9th respectively, and two with the 25th and 28th. The coldest of the four weeks was that which ended April 25, 1908, and in this the mean temperature was 39.7 degrees or 10.3 degrees below the average; the mean maximum temperature was 46.0 degrees, or 12.0 below the average, and the mean minimum temperature 34.4 degrees, or 8.6 below the average. The next coldest week in April was that ended on the 8th inst. In this the mean was 37.4 degrees or 7.6 degrees below, the maximum mean 46.0 degrees or 12.0 degrees below, and the minimum mean 33.4 degrees, or 8.6 degrees below. It will be seen from the foregoing figures, that in the first week of the present month the mean temperature was 2.3 degrees below that of the week ended with April 25, 1908, but owing to the average temperature being lower at the beginning of the month than towards the end, the difference from the average is less. The effect upon vegetation of a temperature considerably below the average is very different in the two periods. The most important of the several kinds of hardy fruits had not, except in early districts, expanded their blossoms, whereas in 1908 most kinds were in bloom, or had flowered and set their fruit, and as the result their crops were the most complete failures that have yet been recorded. Early crops have this year been much retarded by the cold weather, but we may hope the damage done to them will be less than in 1908.

Flowers for Charity.—The citizens of Geneva have recently provided themselves with a motor-ambulance, for which they had great need, at a cost of £720. To raise this large sum it was arranged to have a sale of flowers in the streets, and in this upwards of seven hundred girls were engaged. The result we learn was highly satisfactory.

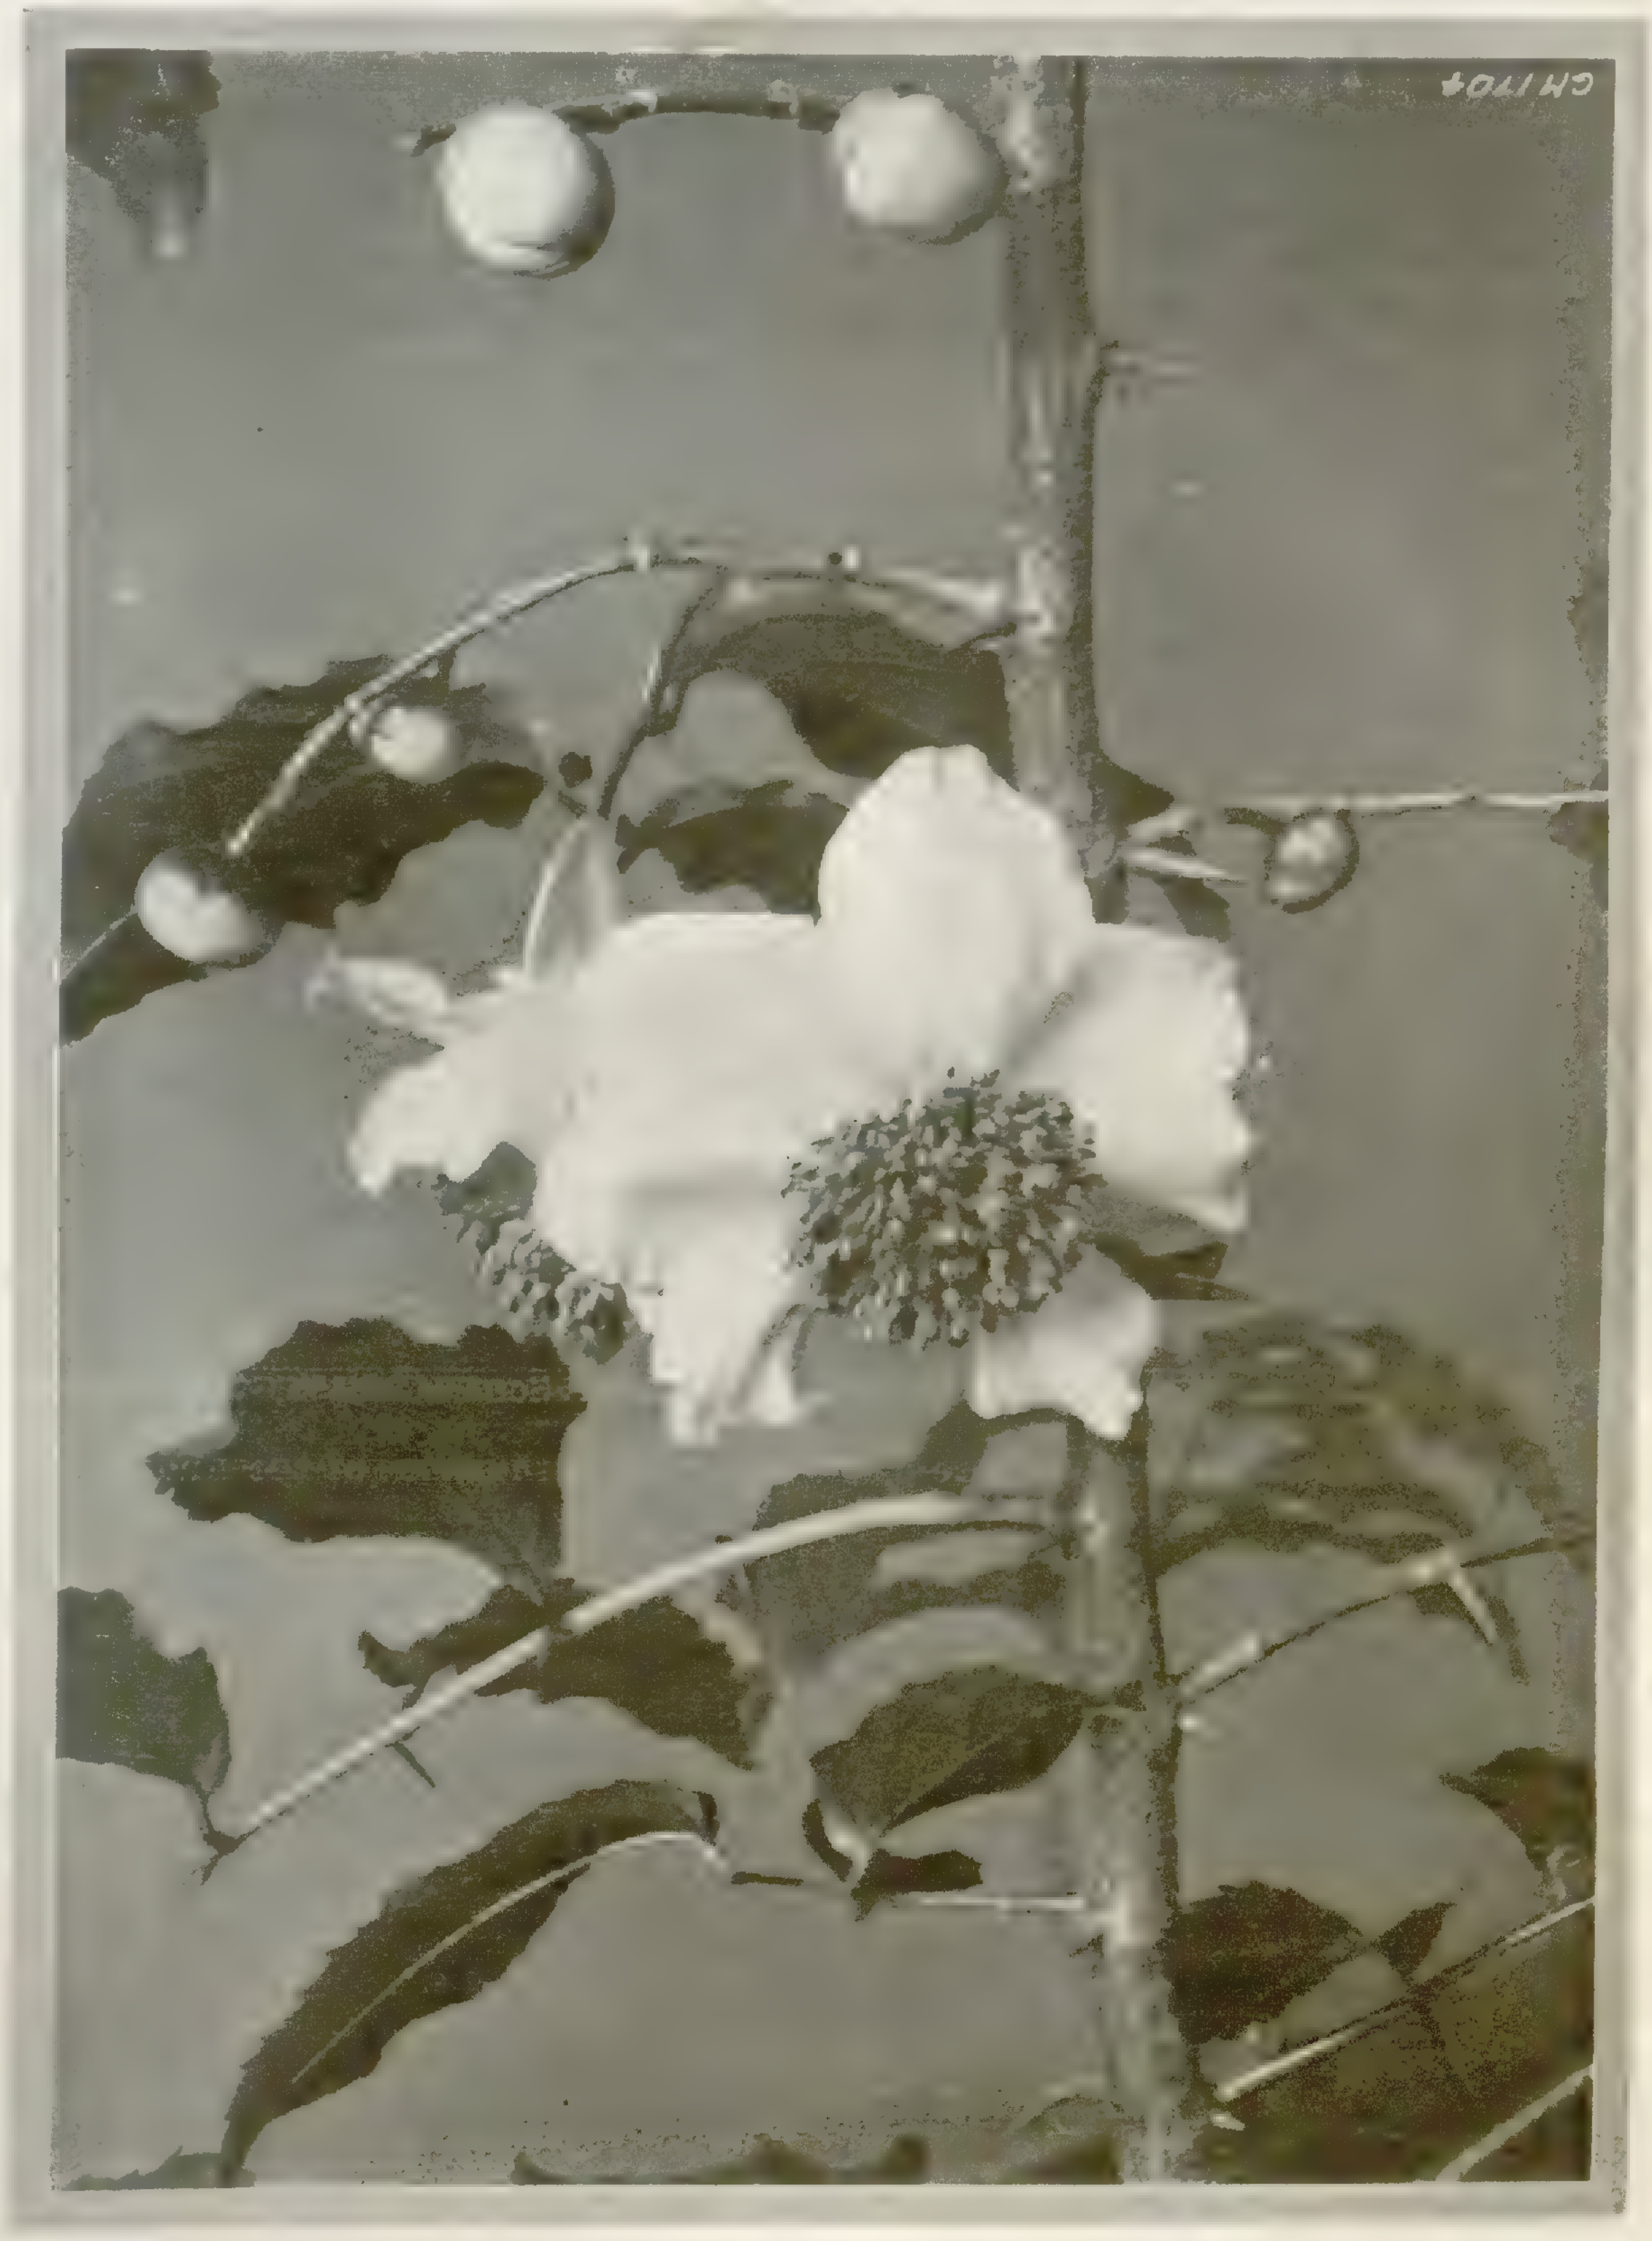
Preservation of Trees in Towns.—In an admirable lecture on "Tree Planting in Towns," delivered at the Town Planning Exhibition in Edinburgh, Mr. E. P. Stebbing deals at length in a most interesting way with the subject of planting trees in towns, but we are delighted to find he does not overlook trees existing on sites where towns or houses are to be planned. He said "There is one other point, however, in connection with tree planting in towns which applies alike to Edinburgh and all growing cities and towns. It is concerned, not with tree planting, but with tree felling. It is difficult to speak too strongly in disapprobation of the indiscriminate and pernicious felling of trees which usually takes place when a new block of houses is to be built or a new road laid down. No effort is made to first mark out the foundations or alignment to ascertain whether the trees must come down or can be left to afford a pleasing amenity to the district. Perhaps for the gain of a few shillings, or through ignorance or gross stupidity, they are ruthlessly hacked down, a few hours destroying the work of a century, and the stumps remain a lasting source of regret to those inhabiting the district, for they can never hope in their time to replace the trees so mercilessly destroyed. The first rule for a town-planning committee to lay down should be that no trees on areas in which building extensions are to take place should be felled or killed without a special permission being previously obtained."

Plants Poisonous to Live Stock.—Those of our readers who have the care of live stock will be interested to learn, on the authority of a well-known writer in the "Agricultural Gazette," that buttercups, white bryony, hemlock, cowbane, water dropwort, fool's parsley, bittersweet, sheep's sorrel, dog's mercury, acorns and meadow saffron are readily obtained by live stock and may prove harmful. Saffron, however, is rarely eaten, and sheep's sorrel is not usually harmful, while buttercups, though harmful in the green state, are harmless when in the form of hay. Plants that may cause poisoning, and which are sometimes within the reach of live stock, are foxglove, hellebore, monkshood, poppies, corn cockle, ivy, hound's tongue, rhododendron, yew, darnel, deadly nightshade, and laburnum.

Electricity in Plant Culture.—At the recent monthly meeting of the Farmers' Club Professor J. H. Priestley, of Bristol University read a paper on "Electricity as a factor in Crop Production." After referring at some length to the experiments that have of late been made with high tension electricity in the cultivation of farm crops, he gave an account of some experiments with mercury vapour lamps in the raising of garden crops under glass. He stated that Miss E. J. Dudgeon had in her experiments found the Cooper-Hewitt mercury vapour lamp "extraordinarily efficacious, producing accelerated germination, increased growth, greater depth of colour, and, more important still, no signs of the lanky, unnatural extension of the plant usually associated with forcing." Figures were also given showing how many days earlier seeds germinated under the lamp than in the control greenhouse: French beans, 8; carrot, 15; cauliflower, 20; lettuce, 6; oats, 5; barley, 5; wheat, 8. The lamp was 4ft. above the seeds, and the light was turned on two hours daily after daylight. Professor Priestley said that microscopic examination confirmed Miss Dudgeon's statements regarding the greater sturdiness of the treated plants. The treated plants and those in the control greenhouse had thermometers beside them, and the reading showed no difference. Professor Priestley said that he had experimented himself with the quartz mercury vapour lamp, and found germination "enormously accelerated" and the treated seedlings "extraordinarily sturdy." One result of the lamp-light was that mustard exposed at close range was absolutely without hairs, while the seedlings at some distance had hairs only on the sides of their leaves and stems next the lamp.

ROYAL HORTICULTURAL SOCIETY.

It was a great and beautiful show that greeted the Fellows of the R.H.S. on April 11; there were alpine flowers, flowering shrubs in profusion, a rare array of daffodils, and gorgeous orchids. There was a big crowd to inspect the exhibits, and once again the arrangement of tabling was altered; in the northern half the tables were lengthways, and in the other half crossways, and there was only one means of communication between the two halves of the show; the crush, however, in places, was fully as great as usual. A bigger hall was needed.



ONCOBA SPECIOSA, VAR. ROUTLEDGEI.
Flowers pure white, with golden anthers. F.C.C., R.H.S., April 11. C. E. Shea, Esq.

FLORAL COMMITTEE.

Messrs. R. and G. Cuthbert, Southgate, N., arranged a beautiful display of forced shrubs in a corner of the hall. Tall cocos palms occupied the background, while tall specimen weigelas, lilacs in variety, and laburnums were raised gracefully above a groundwork of well-flowered Azalea mollis, magnolias, and lilacs, the whole being finished off with ferns and other appropriate plants.

The Misses Le Lacheur and Sherris, Henfield, Sussex, had a table of myosotis and polyanthuses.

Messrs. W. Wells and Co., Lim., Merstham, Surrey displayed the white carnation

White House in fine form, also one or two very promising seedlings.

Auriculas from Mr. James Douglas, Edenside, Great Bookham, gave one a real feeling of April, in contrast to the weather. The plants were in good form, and the flowers in fine condition; the most attractive were Admiration, May Day, George Rudd, Old Rose, and Innocence; a truly fine early display of these charming flowers.

The Guildford Hardy Plant Company, Guildford, had a pleasing exhibit of hardy flowers. The primulas were most interesting, as were also the clumps of Viola gracilis, arabis in variety, and Tulipa Greigi.

From Mr. Charles Turner, Slough, came a fine table of Rhododendron Countess of Sefton, which were growing in pots. The delicate white flowers, slightly shaded with pink, were quite a source of interest with the visitors.

Mr. M. Prichard, Christchurch, Hants, contributed one of his well-known exhibits of hardy flowers, and, on this occasion, did full justice to his reputation. A few of the leading subjects were Fritillaria imperialis lutea and F. rubra maxima; anemones, too, were in splendid form, as were also the bold mounds of double primroses, and groups of P. nivalis and rosea, while the saxifragas and Viola rupestris contributed attractive features.

Mr. George Prince, Longworth, Oxford, had a fine exhibit of roses, chiefly the newer varieties, as represented by Rayon d'Or, in fine colour, Lady Hillingdon, Lady Pirrie, and Lyon. A few standards and climbing specimens relieved the tables. The dwarf polyantha variety, Tip-Top, was attractive, while the specimen roses in boxes were really good.

Another rock and alpine display was that from Mr. W. H. Paine, The Tully Nurseries, Kildare. The arrangement was most pleasing, while the chief features of the exhibit were the primulas, with Gentiana acaulis, and Lithospermum Heavenly Blue. The alpine Violas papilio and gracilis, too, were features.

Messrs. W. Paul and Son, Lim., Waltham Cross, Herts, occupied a table with roses in pots. Needless to say, the plants were in perfect condition, and the flowers timed well for the show. The most notable varieties were Juliet, Albatross, F. H. Veitch, and Margaret. The climbing varieties were also well flowered, especially Sylvia, a fine white variety, said to be perpetual.

Rock and alpine plants from Messrs. T. S. Ware, Lim., Feltham, were arranged naturally. The primroses formed quite a feature, being arranged in blocks of colour. The aubrietias, too, were a fine collection, while irises in variety were much admired.

Carnations from Messrs. Young and Co., Cheltenham, were worthy of notice, especially the vases of Marmion, Winsor, Enchantress, and Britannia; all of them being especially bright.

A most attractive group of forced shrubs and trees came from Messrs. James Veitch and Sons, Lim., Chelsea. The standard trees including fine examples of Cratægus oxyacantha multiplex, Spiræa confusa, and a variety of pyruses, while the groundwork was composed with fine groups of Rhododendron Pink Pearl, Mirabile, and Handsworth Early Red, while azaleas and lilacs formed a profusion of bloom, and added to the beauty of the exhibit.

Messrs. W. Cutbush and Son, Highgate, had a large miscellaneous exhibit, which consisted of fine specimen azaleas, lilacs in variety, and other forced shrubs, while rock and alpine plants occupied boxes in front. The same firm also staged some fine carnations arranged in tall vases. The best were Mrs. Fortescue, Enchantress, Pink Delight, Beacon, and the beautiful Lady Coventry.

Mr. H. N. Ellison, West Bromwich, once again staged a charming collection of gerbera hybrids, which presented a very wide range of colours, also a quantity of ferns, chiefly of a decorative type.

Hardy flowers, most beautifully arranged, came from Messrs. G. and A. Clark, Lim., Dover. The primroses included in the group denoted a very fine strain, and as they were arranged to colour they had a pleasing effect. Anemones and aubrietias, too, were most prominent.

Roses with long stems were the order of Messrs. G. Mount and Sons, Lim., Canterbury, and very fine they were, too. Richmond was in fine fettle, while White Killarney proved a source of attraction with its well-developed buds; other varieties equally good were Lady Hillingdon and Joseph Lowe.

The zonal pelargoniums of Messrs. H. Cannell and Sons, Swanley, maintained the reputation of the firm for these flowers. In addition to a large collection of single varieties, which were remarkably fine in size and colour, the firm staged a basket of Salmon Paul Crampel and Maxim Kevalesky (A.M.), an orange-scarlet bedding variety, quite distinct in colour, and said to possess a good habit.

Mr. C. E. Shea, The Elms, Foots Cray, Kent, exhibited a well-flowered specimen of the beautiful Oncoba speciosa Routledgei (F.C.C.), an evergreen greenhouse shrub, that he has received from Central Africa. The shrub is elegant in growth, and bears pure white single flowers, which have their beauty greatly enhanced by a cluster of rich golden stamens in the centre.

Some delightful plumose nephrolepis, notably N. Marshalli compacta (F.C.C.), "perfectly sweet," as the ladies said, were finely shown by Messrs. H. B. May and Sons, Edmonton, who also staged polyantha roses and some finely-flowered clematis in small pots.

Perpetual carnations were grandly shown by Mr. H. Burnett, Guernsey, who staged full-sized blooms of exquisite colour; Emperor, R. F. Felton, White Enchantress, Rose Doré, Marmion, the splendid Mrs. C. F. Raphael, Mikādo, and Pluto were the leading varieties in a superb exhibit.

Messrs. Pulhams, Elsenham, Essex, contributed a little alpine gărden, furnished with aubrietias, adonis, primulas, Viola gracilis, phloxes, and other pretty spring flowers.

Primula rosea was especially well shown by Messrs. Bakers, Wolverhampton, who also contributed Incarvillea grandiflora, Primula denticulata, Daphne cneorum, Arabis aubrietioides, and other pretty things.

Azaleas were finely shown by Messrs. Jas. Veitch and Sons, Chelsea, the examples of J. T. D. Llewelyn, and Niobe were superb; lilacs and anthuriums of the Andreanum section were also presented in fine style.

A large exhibit from Messrs. Stuart Low and Co., Enfield, included a collection of perpetual carnations, with the pink variety Lady Alington showing up finely; the new Hydrangea Madame Mouillère was also well shown, as were acacias, and a very beautiful set of gerbera hybrids, yellow, whitish, orange, pink, and scarlet being colours well represented.

Caladiums, as shown by Messrs. J. Peed and Sons, Norwood, were a foretaste of summer; the plants were small, but their wonderful and brilliant leaves attracted much attention.

Mr. Clarence Elliott, Seven Hills, Stevenage, set up a little rock garden, and in it were pretty colonies of Scilla siberica and its white form, the golden Morisia hypogæa, Saxifraga oppositifolia var. W. A. Clarke, Androsace sempervivoides, Puschkinea libanotica, the delightful Primula Mrs. J. H. Wilson, and the dainty little Ranunculus crenatus, with white flowers.

Besides their daffodils Messrs. Barr and Sons, Covent Garden, put up a group of alpines, such as aubrietias, Viola cornuta, V. c. papilio, V. gracilis, primulas in variety, anemones, and saxifragas.

A glorious lot of polyanthuses from Messrs. Blackmore and Langdon, Twerton Hill, Bath, attracted a great deal of attention; the white, yellow, and crimson selfs were particularly good, but other shades and combinations of colour were almost as effective.

Mr. A. Hemsley, Crawley, had a considerable rock garden, and, in addition to small flowering shrubs, he had Androsace coronopifolia, Primula denticulata, P. rosea, the double Caltha palustris, the new and dainty Androsace carnea alba, Primula frondosa, aubrietias, etc.

Messrs. Heath and Son, Cheltenham, presented a quite large rock garden, but the rocks were a trifle too obtrusive; very pretty were the colonies of Viola gracilis, Primula rosea, P. cashmeriana, Anemone nemorosa robusta, pale forms of P. japonica, Saxifraga lingulata, and the charming Arabis Billardieri rosea; Townsendia Wilcoxiana, Primula capitata, Lanakea radicans, and Anemone ranunculoides were also interesting.

The cut pelargoniums from Mr. Vincent Slade, Taunton, made a blaze of colour, and such semi-double varieties as Reverie, Charvarris, Hermanos, Fascination, Pres. Baillet, and Paul Reboux were notably good.

Herbaceous and alpine plants from Mr. James Box, Lindfield, Sussex, included Trillium grandiflorum, Aubrietia Purple Robe, Anemone fulgens, tree pæonies, Gentiana acaulis, Primula rosea, P. Sieboldi, aubrietias, and polyanthuses.

Very showy was the big group of flowering shrubs staged by Mr. L. R. Russell, Richmond; Azalea Anthony Koster was the great feature of the group, but Weigela alba, W. Eva Rathke, Pyrus malus Schiedeckeri, lilacs, clematis in small pots, and Spiræa confusa added greatly to the interest and effectiveness of the exhibit.

The group of rhododendrons staged by Messrs. John Waterer and Sons, Lim., Bagshot, was a fine feature; some of the best varieties, all shapely plants and finely flowered, were Handsworth White, Grand Arab, Sun of Austerlitz, the large-flowered George Hardy, with white blooms, and the showy Ascot Brilliant.

A particularly attractive group, most artistically set out, by Messrs. James Carter and Co., Raynes Park, was the centre of an admiring crowd all day. Here, with a background of dark conifers, rising above a rockery bank; in front a lovely green lawn, with a pair of circular beds of hyacinths, each with a tall central leaden vase filled with lovely flowers of King Alfred daffodil. Right in the centre was a big old leaden cistern of 1769 date, and finely modelled, filled with a mass of golden King Alfred daffodils. Primroses, polyanthuses, daphnes, cytisus, and other pretty plants adorned the surrounding rockwork, and a little pool, with its dripping water, completed a very delightful exhibit.

ORCHID COMMITTEE.

The exhibit from Mr. J. Hale, gardener to S. Larkin, Esq., Ridgeway, Haslemere, Surrey, contained Phalænopsis Schilleriana, odontoglossums in variety, Vanda suavis, and a few cypripediums.

Mr. E. V. Low, Vale Bridge, Haywards Heath, brought up Cymbidium insigne in fine form, several plants of the beautiful Brassocattleya Langleyense, Lælio-cattleya callistoglossa, Dendrobium Thwaitesi, etc.

Messrs. J. and A. McBean, Cooksbridge, presented a pretty group of orchids, in which light varieties of Odontoglossum crispum were especially good; with these were Cattleya Schröderæ, Epiphronitis Veitchi, Dendrobium Dearei, and the old Ada aurantiaca.

Miltonia Bleuana var. Peetersiæ (F.C.C.), curiously marked with mauve-purple, was shown by Mr. E. Demunter, gardener to F. Lambeau, Esq., Brussels; the plant carried three spikes.

Messrs. A. Peeters and Son, Brussels, sent over Miltonia Bleuana var. Laeken, a beautiful large-flowered variety.

The superb Cattleya Schröderæ The Baron, with four flowers, was shown by Mr. Alexander, grower to Lieut.-Colonel Sir G. Holford, Westonbirt, Gloucester.

Mr. Black, gardener to R. G. Thwaites, Esq., Streatham, showed several odontiodas; and Odontioda Charlesworthi superba, from W. Thompson, Esq., Walton Grange, Stone, was so fine in substance, colour, and spike, that one wondered how it failed to secure official recognition.

From the Gatton Park collection, Reigate, Mr. Collier, gardener to Sir Jeremiah Colman, Bart., staged Phaius Norman with good

(Continued on page 291.)

SOME NEW PERPETUAL CARNATIONS.

There are some promising additions to our perpetual carnations, and perhaps the variety which attracts most attention is R. F. Felton. Some beautiful blooms have recently been shown at the Royal Horticultural Society's meetings, and, apart from this, it has much to recommend it, and if it does not possess all the good qualities claimed for it, there are sufficient to merit its being grown extensively. It resembles both Mrs. Burnett and Enchantress, and may be a cross between these two varieties; of this I am not sure, neither am I quite sure who is most honoured by it, the raiser, or the gentleman whose name it bears. It is to be hoped that it will not develop rust to the extent that Mrs. Burnett has done, but as "rust" is largely a question of local surroundings and cultural detail, it should not trouble the good growers.

Lady Allington is a carnation of very attractive colour, and should be in great demand, not only for the shade of colour, but more so for its rich scent; the latter quality should enhance its merits, as many of the newer varieties can scarcely claim to have perfume. This variety appears to be of very good constitution and growth. Niagara and White House are very promising varieties, but as whites are not so much in demand these do not command the same amount of attention as other colours. For the private grower a couple of good whites, providing they are the best, is enough. Carola is a beautiful crimson, but I have not seen any blooms yet to equal those staged by Mr. Engelmann. He shows it superbly. I do not know if his plants show any rust, but I notice in many places the variety is subject to it; but this may be through improper treatment during winter. A variety said to be more refined in colour than Carola is one named Pluto, but this has its weak points, and while it may prove a rival, it will be some time before it displaces the latter.

Mrs. C. F. Raphael is more of a Malmaison in appearance, though it is claimed for the perpetual section, but I doubt if it will be a winter-flowering variety altogether. The blooms are too massive for the dull days of winter. There is plenty of room for a good yellow, for R. Whitcombe Riley is very disappointing; its blooms often curl when opening, and its constitution does not appear to be of the best. So far a good yellow has not been obtained. There are several yellow varieties which show white or pink splashes, and I know from my own experience it is difficult to get a good fixed yellow with sufficient good points to be satisfactory. We want a yellow variety of Audrey Campbell shade, or a bit deeper in colour, one possessing a good constitution, and also perpetual enough to flower through the winter.

Mrs. Tatton is a pink and white flower much in the way of Marmion, but the pink is not so deep in shade. Dorothy Gordon very closely resembles Rose-pink Enchantress, and may eventually be found too nearly like that variety. Scarlet Glow may displace some of the reds or scarlets now grown; it certainly is very brilliant, and the colour does not "dull" as in some of this shade, to wit, Britannia, which is about the worst fault this variety shows.

No doubt as more English or Guernsey seedlings are raised we shall have carnations better suited to our winter climate. Many of the American varieties are disappointing, and although little fault can be found with the descriptions of the raisers, it takes two years to prove them under our climatic conditions, they should therefore not be condemned too quickly, while, on the other hand, the descriptions should be taken "cum grano salis."

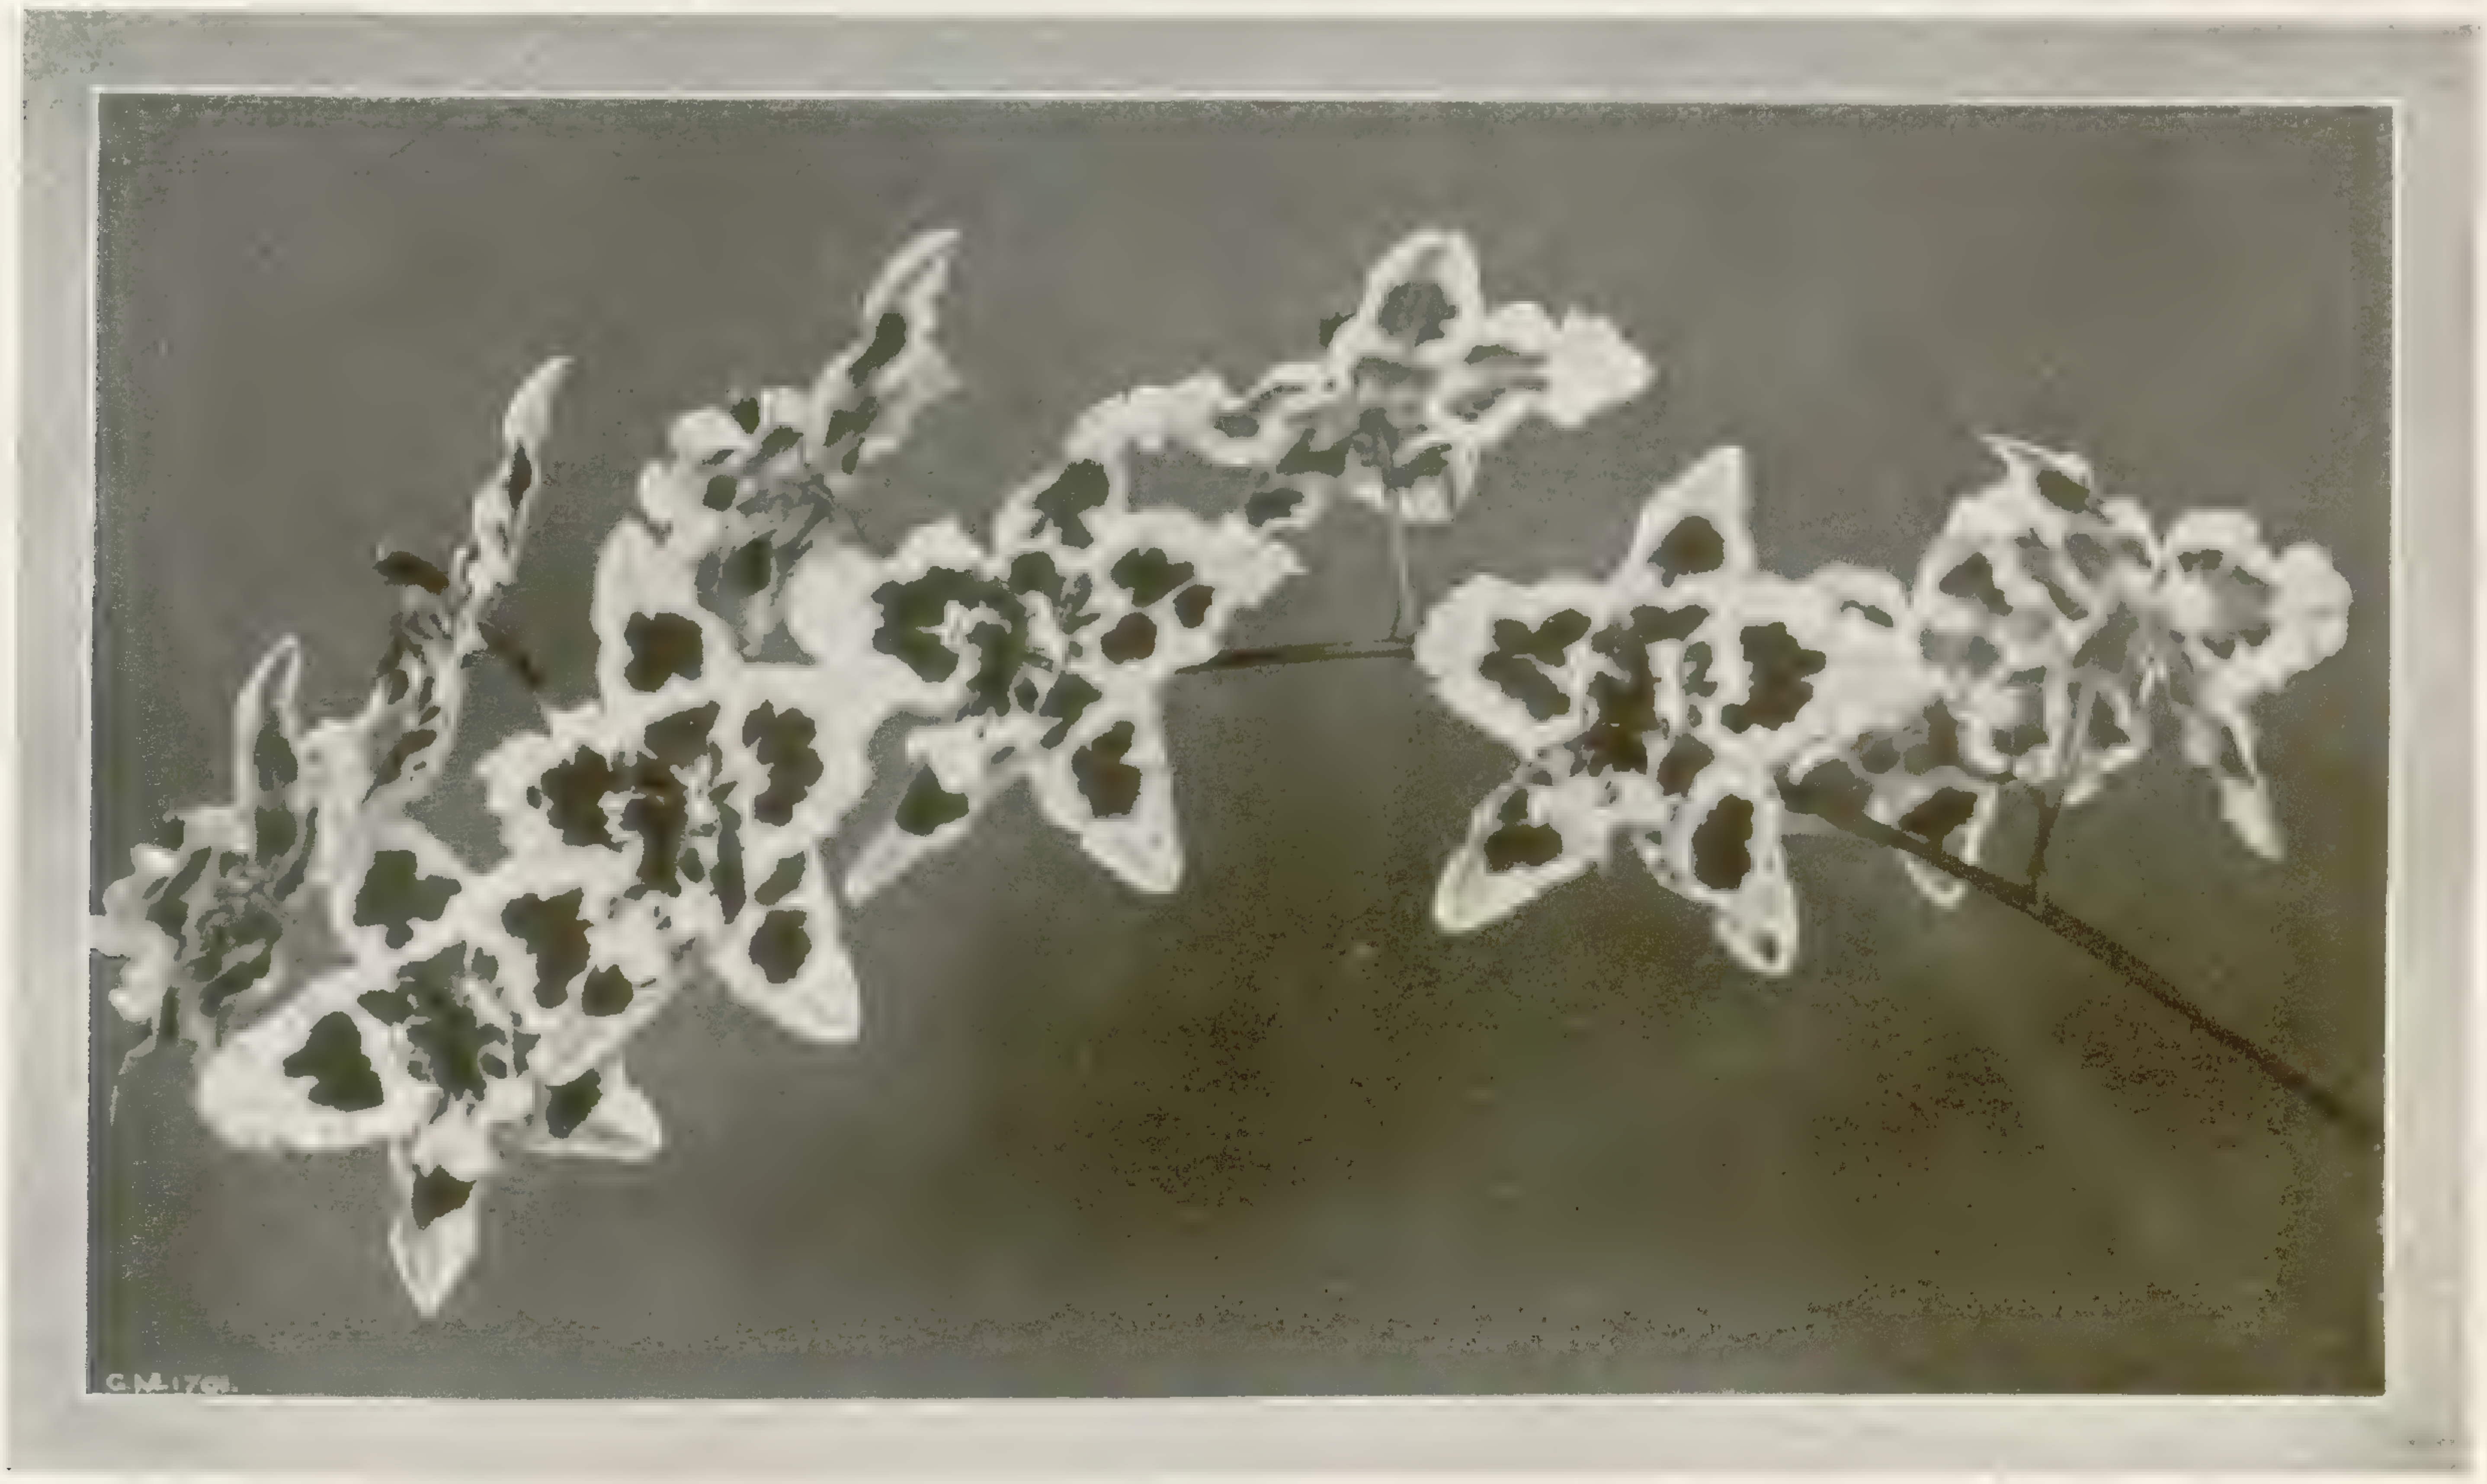
The demand for perpetual carnations still grows apace, which is not to be wondered at, considering their usefulness as cut blooms and as a flower which never appears out of place when arranged either in separate colours or mixed.

T. H. SLADE.

ODONTOGLOSSUM SPLENDIDISSIMUM OAKWOOD VARIETY.

The subject of the accompanying illustration was derived from the intercrossing of O. ardentissimum Oakwood variety and O. Pescatorei Veitchi. The O. ardentissimum was the result of crossing O. crispum Cooksonianum and O. Pescatorei Veitchi. In this secondary hybrid is included, therefore, two infusions of the rare O. Pescatorei Veitchi. The flowers are rather larger than those of the O. Pescatorei parent. The ground colour of the sepals and petals is white, suffused with rose, reflected from the purple colouring on the exterior of these segments. The spots and blotches are violet-purple. The broad lip has brownish-purple markings in front of the yellow disc. Unlike most secondary hybrids, there is very little variation among the plants, and it is possible the cause of the slight variations observable may be attributed to their more or less robust constitution. The plants were raised in the Oakwood collection, being one of the crosses the late Mr. Norman Cookson took a particular interest in. The plants flowered for the first time in the autumn of 1908.

H. J. C.



ODONTOGLOSSUM SPLENDIDISSIMUM OAKWOOD VARIETY.
A beautiful variety of the fine hybrid raised at Oakwood, Wylam-on-Tyne. The flowers white, suffused with rose, and spotted and blotched with violet-purple.

Camellia reticulata. — This Chinese species of camellia has certainly made headway in popular favour within the last few years, a result not to be surprised at, for it is a very beautiful kind, and quite distinct from Camellia japonica and its numerous forms. It has been several times exhibited this spring, but usually in the shape of small plants, in which manner it is not seen to so great an advantage as in larger specimens. The main features in which C. reticulata differs from its Japanese relative are the dull, not shining leaves, which when young have a reddish tinge, but particularly in its large informal flowers of a semi-double character. The petals are more or less undulated, and of a bright rosy-red colour.—W. T.

FERNS FOR ROCK GARDEN ADORNMENT.

The value of ferns for embellishing portions of the larger rock gardens, especially those which enjoy partially sheltered inland situations, is hardly ever appreciated to the full. In spite of the spirited advocacy of fern culture by Mr. Druery and a few other enthusiasts, the cult of the hardy fern has not proceeded to as great an extent as in other and more favoured groups of plants. Notwithstanding this, however, we may still hope for greater progress in the near future from such decorative subjects.

Nowhere, I think, can ferns be utilised to such great advantage as in the larger country gardens, especially those which enjoy the possession of a dell, sloping banks, a wild garden, or even, to take the keynote of this chat—a good rock garden. Ferns are regarded as solitary plants, being refused the additional value of acting in combination with other groups of plants, especially those of a flowering character. How far one could really go in combining ferns with flowering plants in obtaining decorative effects is, indeed, a wide question, but I purpose to briefly touch upon a few phases of such work, in the hope that they may serve to stimulate my readers with a greater love of the hardy ferns.

Many say they have not the suitable soil for fern culture, but, after all, what is this but a poor excuse for not embarking upon their culture? How rich or elaborate is a soil necessary for the cultivation of the polypodium from the tree trunk and the hedge-row, the lastreas from the copses, the scolopendriums from the moist woodland, or polystichums from the hedges and woods? Why, the possession of sloping banks, of valleyed depressions, and half-shady walks, will afford one facilities for the culture of these ferns and many others.

I recollect the turning of heavy clay banks into a veritable home of ferns. And this in a soil that spade would scarcely penetrate. The admixture of rough woodland peat, decayed leaves, and sandstone rubble, speedily altered the condition of the soil, and enabled one to plant without risk of loss, the choicest polystichums, athyriums, polypodiums, etc. With reference to rock-work, I would especially emphasise the fact that the cool interstices and chinks between the rocks provide a glorious opportunity for colonising various hardy ferns. The exquisite tasselled scolopendriums or hart's-tongue ferns delight in such positions in shade, especially if in near proximity to a stream or pool. Varieties such as densum, majus, serratum, robustum, Stansfieldi, and other typical "crispums." The fine forms, like marginatum and undulatum, of cristatum and fimbriatum, as well as others, deserve close attention when planting up the chinks and crevices.

Polypodiums are fine for capping cool rocks in shade, for a waving mass of dainty fronds crowning a rock ledge is decidedly attractive, and the only wonder is that they are not more used for the purpose. The finer forms of P. vulgare are indeed exquisite, and little groups of cambricum, cornubiense, grandiceps, cristatum, elegantissimum, etc., will give a full meed of pleasure when nicely established, and the practically evergreen character of these pretty ferns ought to add a further inducement to the planter. Those two charming ferns P. dryopteris and P. phegopteris, the oak and beech ferns, should be remembered by the planter, for they are exquisite subjects for crowding "en masse" by the sides of old stone steps.

Lastreas, aspidiums, and polytichums are grand when massed upon bold slopes, and the plumose forms of the latter comprise many varieties of especial value. Allosorus crispus, the Parsley Fern, woodsias, and the little walking fern, Camptosorus rhizophyllus, may be successfully naturalised between cool stones or in the crevices between shaded stone steps or stepping-stones. Osmundas and onocleas in variety are grand in moist spots, and a particularly fine specimen of Osmunda regalis, which used to stand in an old Sussex garden at the breaking-point of a spring of water, has always helped to remind me of the value of this fine fern for watery soils. The simple grandeur of Osmunda Claytonia, O. regalis, O. spectablis, etc., of Onoclea sensibilis, and the fine Struthiopteris germanica and S. pennsylvanica, will prove of inestimable value in half-shady spots. One might go on to tell of the wide range of the lastreas and athyriums, of the pretty aspleniums, of blechnums, Ceterach officinarum, cystopteris, Dicksonia punctilobula, and many others, and, in doing so, would but reveal something of the wealth of the hardy ferns.

But it is when the ferns are associated with flowering subjects that their full beauty is portrayed. Tall foxgloves coming up in beauty through the young green smiling fronds of lastreas and athyriums afford an illustration of this, both ferns and blossoms appearing to the fullest advantage. Shade-loving lilies, particularly the charming North American forms are exquisite amongst the ferns. Linarias such as L. Dalmatica, L. vulgaris, etc., the graceful Gaura Lindheimeri, the white Galtonia candicans, and many flowers of like habit are delightful amongst ferns. Cimicifugas, the lighter habited campanulas, astilbes, and many of the spiræas and thalictrums can also be utilised if one has sufficient space at disposal.

And now a word for the dwarfer flowers in conjuction with the lesser ferns. Here opens a wide field for operations. Picture colonies of small ferns, gemmed throughout with stretches of Anemone nemerosa, A. Robinsoni, A. blanda, etc., or with the nodding blue-bells of common thickets, or, if you like, Hyacinthus amethystinus, and the finest varieties of the scillas. Then there are Leucojum vernum, muscari of all types, gold and silvered, frilled and belled narcissi, the exquisite trilliums, primulas of various types, a drift of blue myosotis, masses of gaultheria, of Galax aphylla, of Sedum palustre, of kalmias, and, if you care for them, the charming Irish heaths or Menziesias, with the smaller ferns.

One could go still deeper into the possibilities of the combination of fern and blossom, but I will leave my readers to delve deeper. P. S. Hayward.

Bulbous Irises under Glass.—Few if any other bulbous plants have the richness of colouring, combined with the delicate markings, of this section of iris. From their lower stature and the fact that some of the most striking bloom during the dull winter days, they are not always seen at their best out of doors. They are, however, charming in a cool greenhouse, as under glass the flowers are clean and bright, and being brought near to the eye their subtle tints are more apparent. The best known and the cheapest of this section is I. reticulata, with purple-tinted flowers, and a golden blotch, and a pronounced fragrance of violets. The pale blue I. Bakeriana is charming, and the golden blossoms of I. Danfordiæ impart quite a distinct tint.—W. T.

FORSYTHIAS.

The importance of the various forsythias as decorative shrubs is impressed on us each spring, for they rarely fail to produce a wealth of blossoms, and are comparatively little trouble throughout the year, for once planted in good loamy soil, they continue to give good results for many years; while, should the plants appear to be weakening, a dressing of rotten manure in spring is usually all the attention required to promote fresh vigour. Their propagation is very simple, for, if cuttings of young shoots are inserted in pots of sandy soil in June, and stood in a close frame, roots are formed in the course of two or three weeks.

One species, F. suspensa, is sometimes pruned hard back after flowering to induce strong upright shoots, which may grow to a height of four feet or so. These vigorous branches are usually prolific of flowers, for blossoms appear from almost every bud from base to summit. The same species grown against a wall or trellis usually requires spurring back as soon as the flowers fade, but when grown in a shrubbery in the ordinary way, it, with the other kinds cultivated, may be allowed to go several years without attention from the pruner. As young plants are so easily obtained, and as they grow rapidly, it is seldom worth while to attempt to transplant old examples, as young ones are so much more satisfactory.

There are many uses to which forsythias may be put. As specimen beds they have much to commend them. Groups or single plants in shrubberies give a good account of themselves. Trellis work covered with S. suspensa has a gay appearance during March and early April, while for forcing much may be said in their favour. Large examples lifted from a border in autumn and planted in tubs are excellent where halls or corridors have to be furnished with flowers, while small plants are useful for room decoration.

Of the various kinds grown, F. suspensa, a native of China, is the most useful for general purposes. Under natural conditions it forms fairly erect main branches, with weeping branchlets, but, as previously stated, the habit may be altered by severe pruning as soon as the flowers have faded. The species is somewhat variable in character, both as regards habit, foliage, and flowers, and for this reason the name of F. Fortunei is still sometimes kept up for one form. Both F. Fortunei and F. Sieboldi are, however, simply synonymous with F. suspensa. F. viridissima, another Chinese species, may be readily distinguished from the last-named by reason of its sturdy bushy habit and deep green foliage. The leaves are always simple in this case, whilst in F. suspensa they are sometimes deeply lobed or ternate. The flowers are produced about a fortnight later, and are rather darker in colour.

F. intermedia is a hybrid between the two previously mentioned kinds. It forms a strong bush 8ft. high, intermediate in character. The golden blossoms are borne as freely as in the other instances. Several specially floriferous varieties have recently attracted considerable notice. Good ones are densiflora and spectabilis. They are less dense in habit than the type. A European species was introduced a few years ago under the name of F. europaea, from Albania. This is an upright-growing bush, bearing, like the remainder, yellow flowers. It is, however, of little value as compared with its Asiatic relatives.

W. Dallimore.

A USEFUL SALADING.

For a long period the dandelion has been held in repute for dietetic and medicinal purposes, but whether it has justified any considerable proportion of what has been written and spoken in praise of its virtues is doubtful, and it may be allowed to remain an open question. Upon one point there cannot well be two opinions, and that is the usefulness of its leaves as a salading. Many appreciate the young leaves in a green state, and obtain their supplies from the plants that usually are plentiful in pastures, or from cultivated plants in the garden, as may be the most convenient. When young the green leaves are tender and pleasantly bitter; but in process of development they become somewhat tough, and so bitter as to render them unpleasant to the palate. Cultivated plants, not having to compete with other herbage, continue in full growth for a longer period than do those in a wild state, and therefore afford supplies of tender leaves for a greater length of time. Not only do the latter give a more plentiful yield, but the leaves are more succulent, a point of considerable importance in salading.

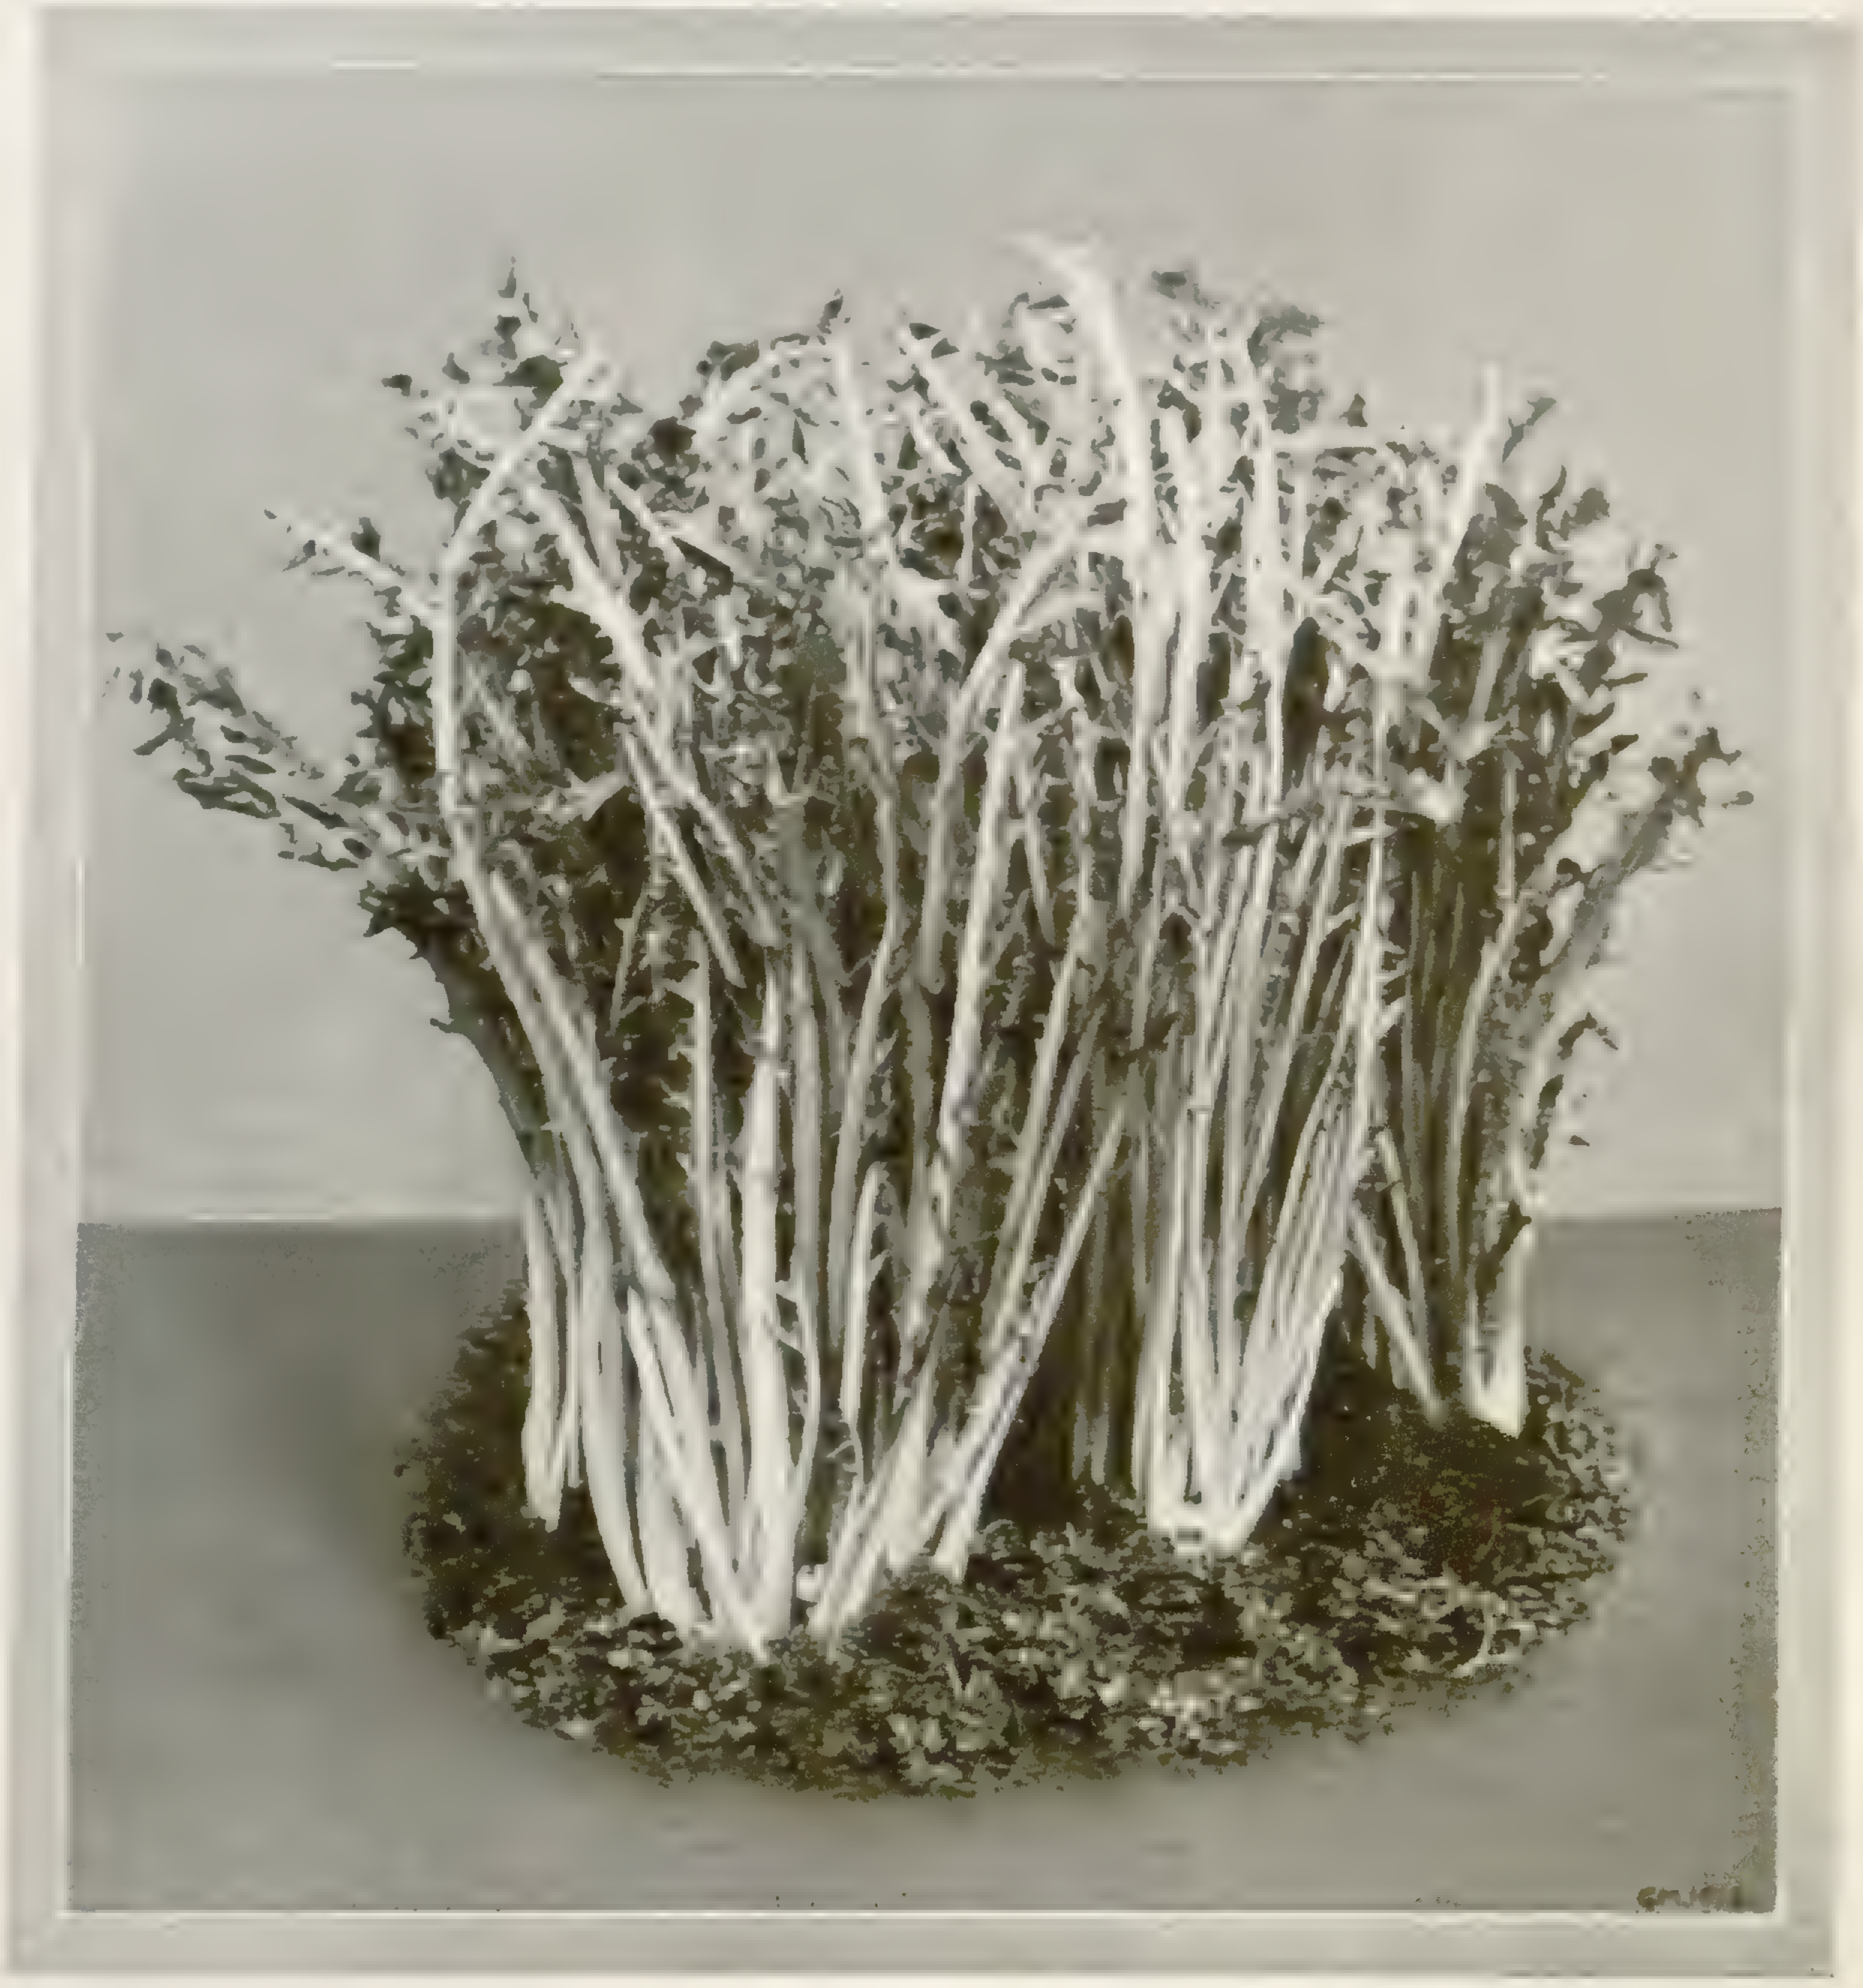
While the green leaves are to those who appreciate their distinctive flavour most useful, their value is small as compared with the blanched leaves which can be had in abundance from early in the winter until the spring season is well advanced. There is nothing difficult in the cultivation of dandelions for the supply of blanched leaves; on the contrary, the details are so simple that it would not be easy to fail in their comprehension. The first step, after a suitable type has been selected, is to set apart a quarter, or a portion of a quarter, according to the supplies that will be required, where the soil was deeply dug early in the winter, but was not manured. As in the case of beet and some other of the root crops, it is essential the soil should be in a fertile state without having had recent applications of manure made to it. An area on which potatoes, onions, or peas were grown in the previous year would answer admirably.

The seed may be sown towards the end of March, but there is no time more suitable for sowing than the present. Sow thinly in shallow drills fifteen inches apart, and in filling in the drills take the usual precaution of drawing the fine soil over the seeds. Within a comparatively short period the seedlings will begin to make their appearance above the surface, and before sufficient growth has been made for injury to result from overcrowding thinning should be commenced. The distance at which the plants should be apart in the rows is twelve inches, and the thinning may be done at one or several operations, but, generally speaking, the best course is to thin gradually, say in two or three operations. Beyond the removal of surplus plants, the only attention that will be required will be the rather frequent use of the hoe to keep down weeds and maintain the surface soil in a loose state.

At the end of October, or early in November, the lifting of the roots may be commenced for the purpose of placing them where they will have the assistance of a temperature sufficient to start them into growth. One that ranges between 55 and 60 degrees is the best; a few degrees below the minimum or above the maximum will not make much difference. A warm cellar or a mushroom house will answer admirably, the latter being preferable, as it will afford the temperature necessary to ensure a free growth without subjecting the roots to hard forcing. Both cellar and mushroom house should be sufficiently dark to ensure the proper blanching of the leaves; but if this is not the case measures must be taken to exclude the light from them. In the mushroom house the roots may be packed rather close together on the shelves with soil between them; but when they are started into growth in cellars it will be a convenience to put them in shallow boxes of such size as will readily admit of their being carried in and out. Late supplies in spring may be obtained from the open ground by early in March turning seven or eight-inch pots over the roots, and covering these with leaves or long litter, arranged in ridge form, to maintain a moderate degree of warmth about them.

The Large-leaved Dandelion herewith illustrated is the best for garden culture, for not only are the leaves large and comparatively thick, but they are produced in much larger numbers than in the case of the type. The specimens illustrated were exhibited by Messrs. Sutton and Sons at the first of the two March meetings held by the Royal Horticultural Society, and attracted much attention from the visitors.

G.



WELL-BLANCHED EXAMPLES OF THE LARGE-LEAVED DANDELION.
Exhibited by Messrs. Sutton and Sons at R.H.S. Meeting held March 14.

Early Figs.—In bright weather these will take copious supplies of water, especially when in shallow borders or in pots—in fact, the best figs are obtained from these borders—when they obtain all that is necessary in the way of moisture and liquid manure. Keep the shoots nicely tied and regulated, and the points pinched out. This will all help the second crop, which in many cases is more prolific than the first. As the fruits begin to ripen less moisture in the air will be necessary.—W. A. Cook.

MAGNOLIA STELLATA.

Among spring-flowering shrubs this bushy species of Magnolia forms a conspicuous object in April, for at that period it is covered with its semi-double, star-like, glistening white blossoms. A native of Japan, it has been known in English gardens for many years, though it was very scarce until quite recently. Within the last twelve or fifteen years, however, a great many plants have been imported from Japan, therefore it is now seen fairly frequently. For the first year or two after importation growth is slow, but after the plants have once become acclimatised they increase in size rapidly. There is no saying to what size it will eventually grow, although plants four feet high and four feet through are accounted fine examples; there are, however, plants in the country very much larger than these dimensions, one at Abbotsbury Castle, in Dorsetshire, being eleven or twelve feet high, and wide in proportion. Like other magnolias, it appreciates a little peat mixed with the soil, and thrives best in light, well-drained material. When selecting a position for the species, preference should be given to one with a west aspect, for, after a frosty night, bright sun on the flowers is apt to seriously injure them. Grown in tubs, the species is useful for greenhouses and conservatories in spring.

CHRYSANTHEMUMS.—For full instructions on the Culture of Early-flowering Chrysanthemums in beds or borders for garden or greenhouse decoration, read the Second Edition of CHRYSANTHEMUMS FOR GARDEN AND GREENHOUSE, by D. B. Crane, price 2s. 6d. net; or by post, 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

WATER GARDENING.

Water gardening has become very popular during recent years, and it is now one of the most fashionable branches of horticulture. There is a certain fascination about it, for when carried out in quite an informal style it makes a pleasant relief to the more formal type of flower gardening, which has so long held sway. One of the charms of a water garden is that it is of necessity unlike another of its kind, for it must depend very largely on the surroundings and the existing natural features for its formation and character.

A situation possessing both sloping and level ground might be considered ideal for a water garden, for therein one can have running streams and spacious pools capable of accommodating every kind of aquatic and bog plant. A gentle slope is probably to be preferred to a level stretch of ground, for, given a natural stream by here and there widening it into pools, utilising a moderate amount of rockwork, and planting suitable trees and shrubs so that only certain portions are visible at one time, one can almost convert it into a veritable panorama of aquatic vegetation. From the high ground at the top of the slope a lovely view of the whole would be obtained, as is the case in the gardens here. Where such conditions as I have mentioned already exist it is an easy matter to plant the site so as to obtain the most artistic effects.

In flat situations, however, much skill and labour will be required to design and carry out a really artistic scheme that will be pleasing and natural when completed. If a few large specimen trees exist on the site they will help to add to its beauty, and also obviate that appearance of newness so very noticeable in some places. The choice of plants to embellish such a garden is very wide, so that there need be no lack of variety, and the majority can be successfully planted at the present time.

In the pools themselves water lilies will be the principle adornments, and to grow these well they require an open situation, where they can receive the full benefit of the sun's rays. The more vigorous species can be planted in the deeper parts of the water. Nymphæa alba, N. candidissima, with large double white flowers; N. marliacea and its varieties, succeed well in deep water; while N. Leydeckeri and N. odorata are suitable for the shallower parts. The present is a good time to divide and replant any that are becoming overcrowded. Replace them in baskets filled with heavy loam, and sink in the positions where they are to grow. Various other water plants may be planted in this way, including Orontium aquaticum (Golden Club), Pontederia cordata, with closely-set blue flowers; Nuphar luteum, the common yellow water lily; and Aponogeton distachyon, which is scented like hawthorn. Calla palustris (the Water Arum); Sagittaria gracilis, S. sagittifolia, the common Arrow Head, and Menyanthes trifoliata (the Bog Bean), should also be included. Such plants as Caltha palustris (the Marsh Marigold), Typha angustifolia, T. latifolia, Phragmites communis, and Butomus umbellatus (the Flowering Rush), are very effective planted on the water's edge.

The banks of the stream and the surrounding marshy places are ideal localities for numerous bog plants, and if planted in masses these form objects of much beauty. Senecio clivorum and S. Wilsonæ are very bright and showy, and they look well associated with some of the fine-leaved bamboos, which are especially ornamental planted on the banks of streams. The lovely Japanese irises, I. Kæmpferi, and Acorus calamus (the Sweet Flag), succeed well close to the water. Rodgersia podophylla, a handsome plant with large peltate leaves, is very striking, while Saxifraga peltata should on no account be overlooked, as its large flower spikes are produced early in the season in advance of its handsome foliage, which is always effective near the water's edge. Arundo donax and Carex japonica are both telling plants. Epilobium angustifolium, with purple flower spikes; Trollius europæus. Funkia Sieboldiana, Hemerocallis aurantiaca, astilbes and spiræas in variety, especially A. Davidi and S. palmata, are very effective.

Osmunda regalis (the Royal Fern) and the broad-leaved Gunnera manicata and G. scabra, must be included. The latter needs a little protection in winter, and in some seasons the handsome leaves reach a height of fully twelve feet. A few of the Japanese maples should be planted in the water garden, as they will furnish some additional pleasing colours. Acer japonicum laciniatum, A. palmatum sanguineum, A. p. dissectum, and A. p. palmatifidum are some of the most showy. Liquidambar styraciflua, the Sweet Gum of the United States, is eminently adapted for such a position, as it succeeds well in a moist loamy soil.

J. Gardner.

LILY OF THE VALLEY.

There are many persons who, not having had much experience in the cultivation of lily of the valley in the open borders, firmly believe that the only position in which this charming flower can succeed is a north border where the soil is fairly heavy. Furthermore, they are under the impression that heavy surface dressings of rich composts are essential every winter.

For many years I grew more than a quarter of an acre of lily of the valley in one garden, in various positions, and had the least satisfactory results from plants growing in north borders. The best results were obtained from those growing in south-west borders and others in the centre of the garden. In time, of course, the soil wears away from the crowns if top-dressing is not afforded. I found that it was a great mistake to allow the plants to become very bare of soil, and then to put on a heavy top-dressing, as the crowns in places seemed to degenerate very much. I generally applied a very light dressing of sifted sandy loam and leaf-soil in equal proportions annually, and with excellent effect. At no time were the crowns entirely buried with the soil.

For a number of years I have observed the progress of some thousands of plants growing in almost pure sand in a wood in which fir trees are dotted about; other kinds of trees and shrubs also grow there, but in the open space the lily of the valley seems quite at home. No further attention than that necessary to keep the plants free from weeds is bestowed upon them, and every year the leaves of the trees and deciduous shrubs are left to decay on the lily beds. Stronger and more satisfactory plants I have never seen. In my own case, the soil was a sandy loam. The plants spread rapidly, and we were obliged to dig up some near the box edging every year to prevent them growing on to the pathway. All the plants had, previous to planting in the garden, been forced, and I am quite sure that they may be cultivated successfully in many odd corners in gardens in a natural way.

MORE ABOUT GOOSEBERRIES

My notes on "Mistakes in Gooseberry Growing," which appeared in The Gardeners' Magazine of January 14 last, have been criticised in a way which seems to call for a few words in reply on my part. Both "E. M." and Mr. Hammond take objection to my statement that gooseberry trees are often getting past their best after 12 or 15 years, the latter having trees 20 to 25 years old which are still bearing well. So have I; one tree of Red Champagne which, as a five or six-year-old tree, was planted in its present position in the middle of April, 1881, being still in full vigour of growth and bearing well. But where one tree has lasted 20 or more years, a dozen have been replaced, and, in my judgment, with advantage.

I know there is a great gulf between commercial and private fruit growing, but my space being limited, every tree must be fully efficient if it is to be allowed to occupy the ground. I always keep some young gooseberry bushes in reserve, and these can be moved at the end of October from one part of the garden to another almost without feeling it, even when six or seven years old, and after the first season will produce a fair crop of fruit and soon do better than the old trees they replaced. The efficiency of trees at 15 years old depends a great deal upon the extent to which they have suffered from caterpillars, birds, and other pests.

Mr. Hammond also objects to my statement that gooseberries rarely produce secondary growth after pinching in May. Divorced from its context, this statement is certainly misleading. If all the growths of a gooseberry bush were pinched at that season, probably all of them would break out into growth again, but if the pinching in the latter part of May is confined to the shoots on the inner parts of the bushes, or where there is no room for them to grow during the summer without unduly crowding the tree, the rest of the shoots, and the rapidly swelling crop, provide such a free outlet for the sap that a bush must be remarkably vigorous, or the season very damp, if secondary growth from this pinching is at all general.

I always attach great importance to keeping the bushes open during the summer, both for the sake of the fruit and next year's fruiting wood, and I usually look over the bushes again two or three weeks after the pinching, when any secondary growths that have been made are pinched to one leaf, while some of the primary shoots that are then seen to be crowding the tree are cut back to three, four, or six leaves, according to space available. I can understand that this amount of detailed attention is scarcely practicable in field cultivation.

Alger Petts.

Carter's Harbinger Lettuce is very fine for early culture in frames, and when the supply of salading is in great demand, it is very easily forced in small seed trays or boxes, and grown on in frames or on the shelves in warm houses. It is valuable because it comes into use so quickly. It is not a big-hearting variety, but of very quick growth, and it produces quantities of young tender leaves which are particularly useful. One can sow a box, and prick out a dozen more boxes from it, and if needs be the whole box can be cut for a salad. By weekly sowings a good supply all through the cold season can be easily kept up. These light fresh lettuce are better than old hard stuff, especially when mixed up with chicory, dandelion, mustard and cress, etc., and are therefore much appreciated.—W. A. Cook.

BALSAMS AS POT PLANTS.

These are flowers which have had their day, relatively speaking, like petunias, verbenas, and fuchsias, and it is not always in the superior merits of newer introductions so much as in fashion that the reason for the change is to be sought, most people apparently liking to grow those things which are seen on every exhibition table and grown and talked about by their friends. The double camellia-flowered balsam, more worthy of culture than the rose-flowered form, is as beautiful now as it was a generation or more ago, when it was so popular, and those who like to have a good flower which is not much grown, and is at the same time easy of cultivation, either with or without heat, would not regret the revival of a good old-fashioned flower.

Balsams make excellent pot plants for the conservatory, or, if one does not possess such a place, for use indoors during the summer, enough being grown to permit of the plants being changed every day or two, as they soon show the ill effects of life indoors. Some care should be exercised in procuring the seed, as some seedsmen take but little trouble in keeping a good strain now the seed is not much asked for, and cheap seed will often produce a mixture of singles, rose-coloured doubles, and nondescripts. Seeds may be sown any time during March and April, but for our purpose fairly early in March, in gentle heat, is the best time, otherwise at the end of the month, or early in April, in a frost-proof frame, using light rich soil.

The seedlings come up with a pair of fleshy leaves, and they may be pricked out into small sixties, one in each, as soon as they are beginning to show the third leaf, taking care to prevent the seedlings developing too long a leg, as it detracts from the beauty of the plants. As soon as they are getting well rooted they should be given a shift each time increasing the richness of the soil—turfy loam and rotted manure, cow by preference—the addition of some bone manure helping to lessen the naturally sappy nature of the growth, and increasing the fineness and substance of the flowers. They will eventually need twenty-fours at least, and very good plants a size larger. In the days when the cultivation of balsams was studied they were sometimes given even twelve-inch pots, which meant gross feeding and very coarse plants, but it is doubtful if the flowers were finer, or if the plants produced a more pleasing effect than well-grown specimens in twenty-fours, while for room decoration the smaller size of the pots will certainly be appreciated.

Balsams are gross feeders; when grown in the open ground it is recommended not to give them too rich a soil, because the sappiness of the growth in such conditions is detrimental to the flowers, but there is not much risk of this in pots, though perhaps it is advisable to defer liquid feeding until the flower buds are well in sight. If the finest individual flowers are wanted, the smallest buds may be removed in their early stages. The plants need abundance of water, and all the sunshine they can get. The doubles do not seed much, but any pods produced should be picked off, and this, combined with good feeding, will cause the development of fine flowering laterals, these keeping up a succession of blossom for a couple of months.

P.

BEST PLANTS FOR GREENHOUSE.—Nearly 300 pages are devoted to the description, propagation, and culture of the best flowers and plants for the green house in THE AMATEUR'S GREENHOUSE, by T. W Sanders, price 5s. net, or by post 5s. 6d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

INTERESTING CONIFERS.

It may be interesting to Mr. Dallimore, page 209, and your readers generally, to know that there is a very large tree of Cunninghamia sinensis, forty to fifty feet high, at Holmbush Park, Horsham, the seat of Colonel Clifton Brown. This gentleman showed me the specimen last season during the interval of a cricket match played within sight of it. It is by far the largest specimen I have ever seen, and it does not stand in a particularly sheltered spot; in fact, it is isolated on the lawn and within range of north-east winds, and at a height of several hundred feet. It seems wonderfully strange how this tree should have escaped the frost, as it has done. Several trees have been planted in these gardens during the last three years, and are doing well.

There is a fine specimen of the columnar Libocedrus decurrens in these gardens, and in nearly all photographs that have been taken of the alpine garden it will be noticed towering up to a height of between fifty and sixty feet.

Cupressus Goviniana is one of the most interesting of the whole family, and is supposed to have been discovered by Hartweg in California, and was introduced in 1847. It does not appear to be very much grown or known. The foliage is very fine and thin, but does not give one the impression that it is tender; we have several trees that have been out two winters, and look quite happy and flourishing.

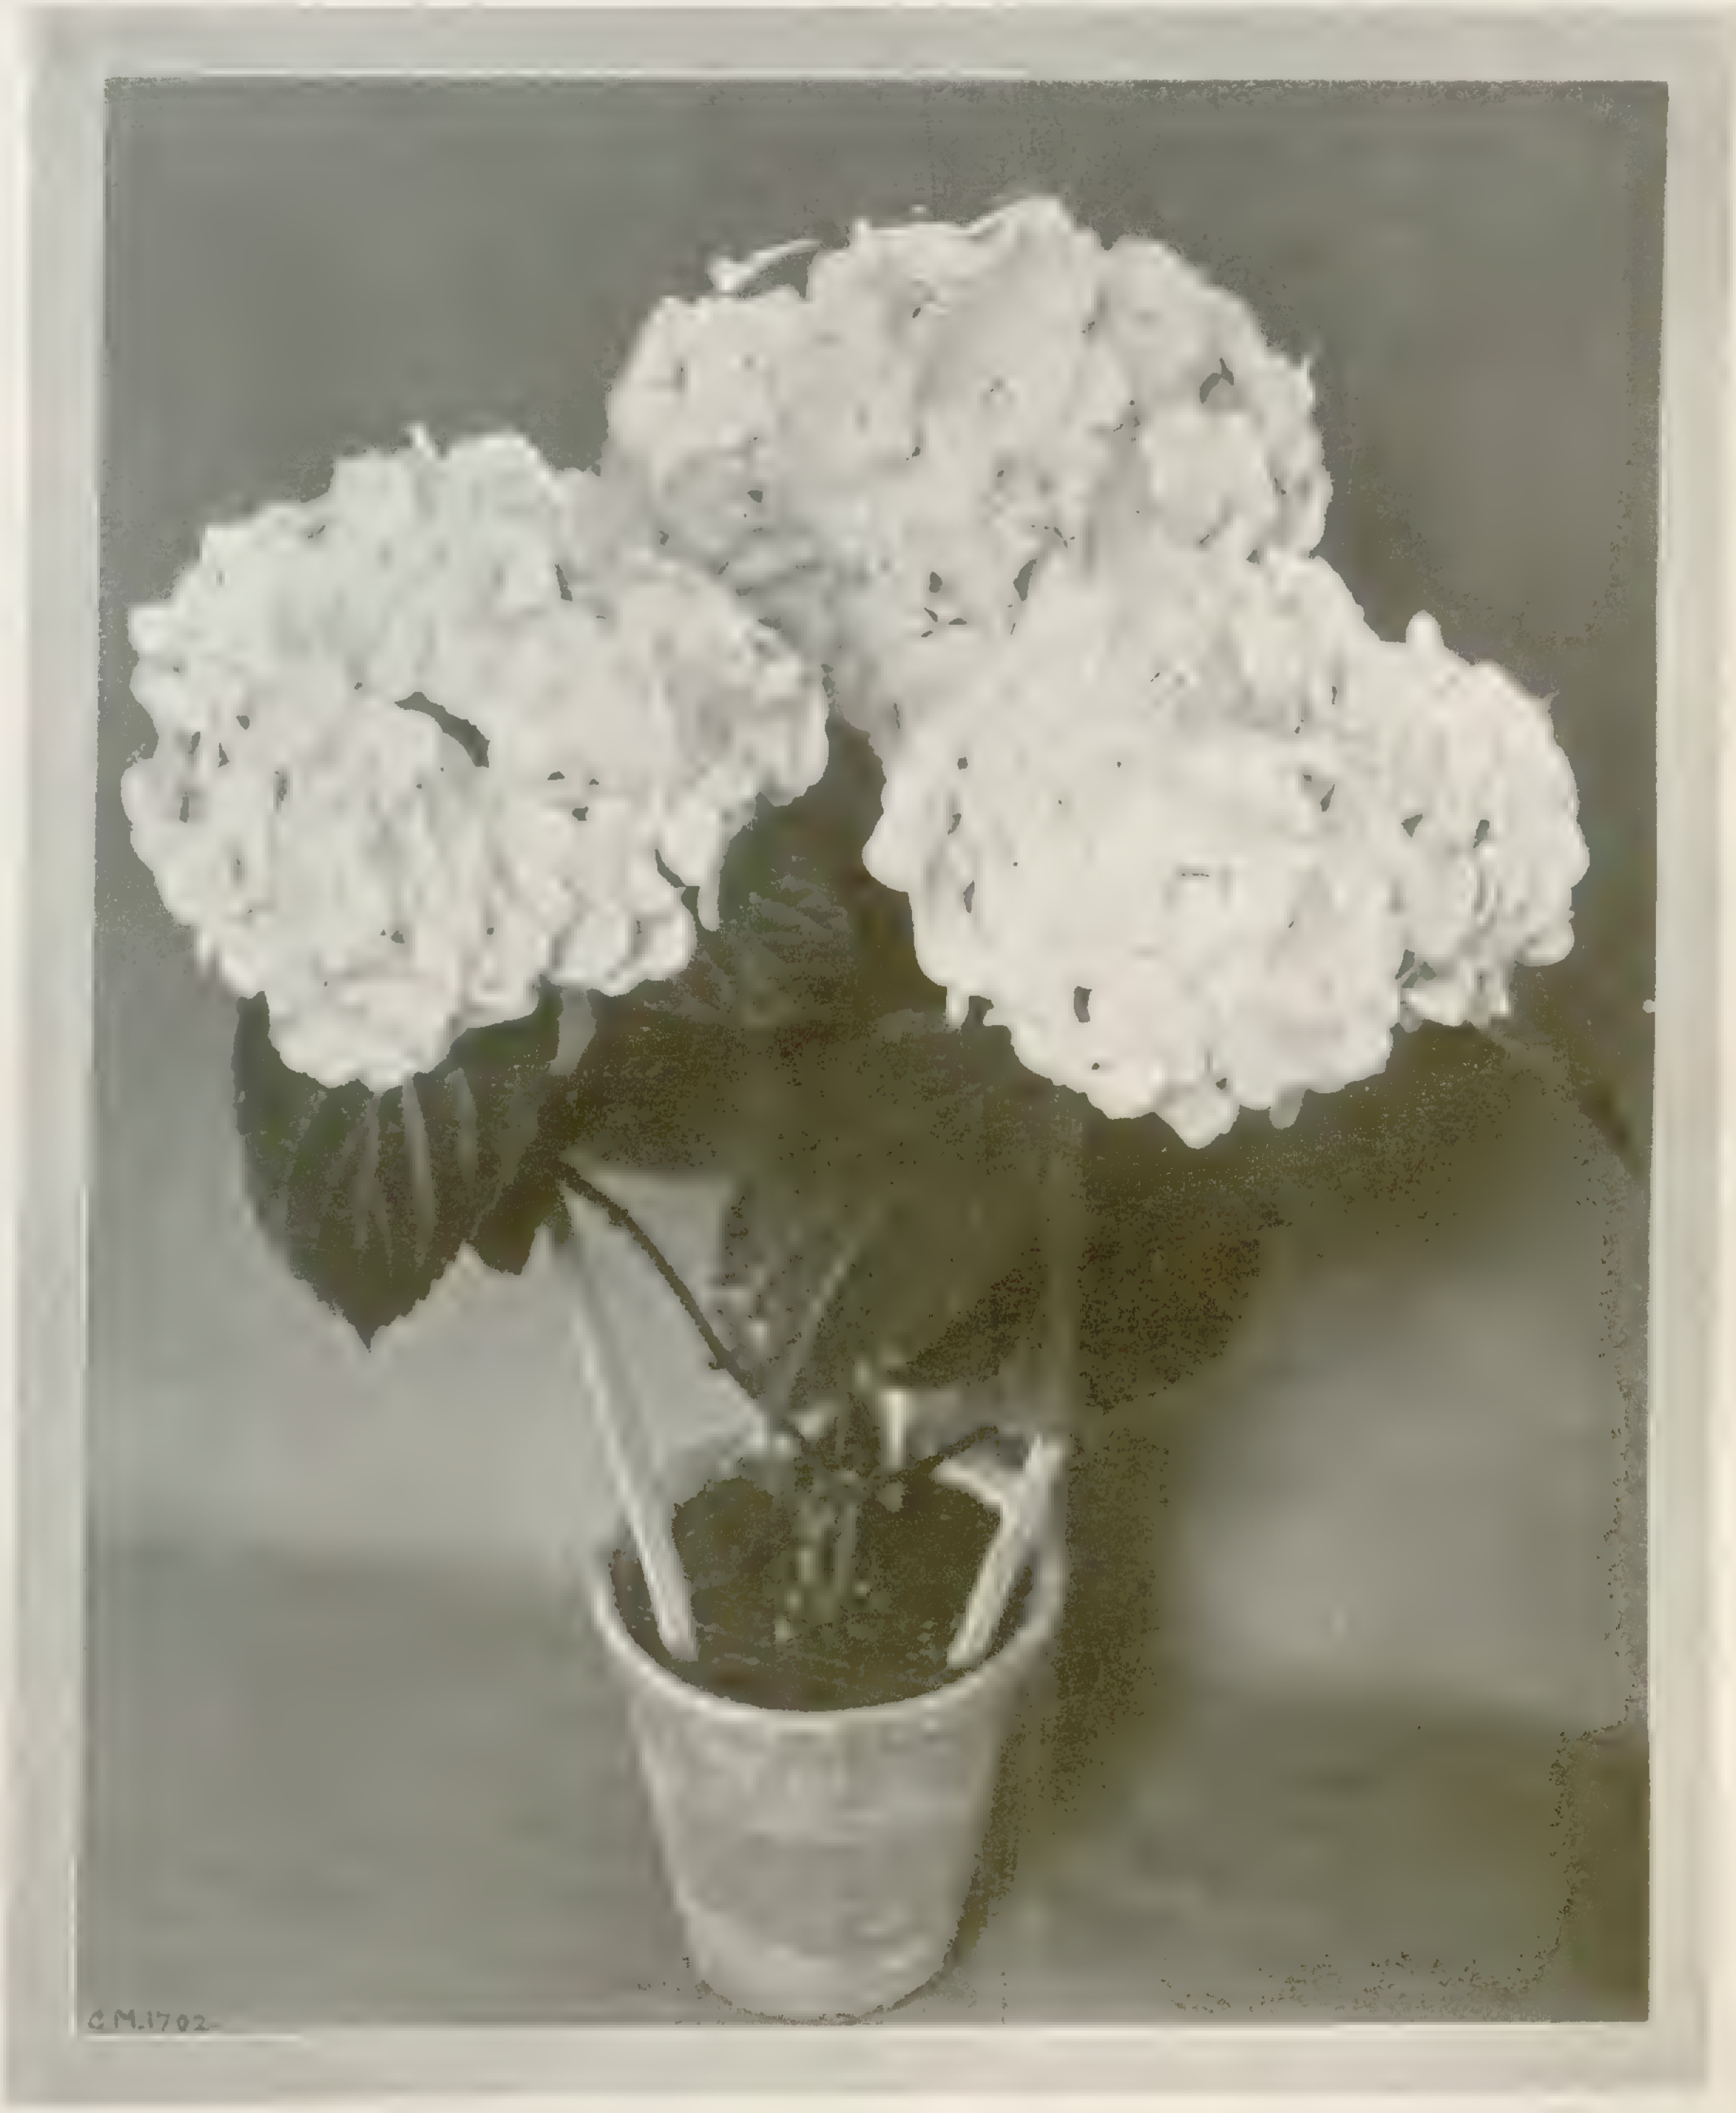
Cupressus cashmeriana is perhaps the prettiest conifer of the whole section, and if it proves hardy it will be an acquisition: but it is well worth trying, for even as a greenhouse plant it is beautiful.

W. A. Cook.

NEW PLANTS, ETC.

HYDRANGEA HORTENSIS MDME. E. MOULLIERE.

A very beautiful variety with large heads of broad white slightly-fringed flowers. It is a famous pot plant, and ought quickly to become popular. We understand it was raised by Mons. E. Moullière, Vendome, France. A.M., R.H.S., March 28; Messrs. Stuart Low and Co., Bush Hill Park, Enfield.



HYDRANGEA HORTENSIS MDME. E. MOULLIERE.
Flower heads large, pure white. A.M., R.H.S., March 28. Messrs. S. Low and Co.

HOULLETIA SANDERI.

This species, from Peru, has been exhibited on several occasions recently at R.H.S. meetings, by Messrs. Sander and Sons, of St. Albans, its importers. The pseudo-bulbs are short, surmounted by a foot-long leaf. The erect scape bears two or three fleshy, inverted flowers, pale yellow, with a golden-yellow central area on the three-lobed lip. The plant is said to flourish under conditions found successful for Lycaste Skinneri. "Bot. Mag.," t. 8,346

POMPON DAHLIAS.

Those who take an active interest in dahlias and their cultivation can hardly fail to highly appreciate the prominence that was given to these flowers in the issue of the Gardeners' Magazine for the 8th inst. I am very glad to see that you fully appreciate the importance of the dahlia as a garden flower, and are endeavouring to induce raisers to give attention to the habit of the plant and the length and rigidity of the flower stems as well as to the size and form of the individual flowers. If they act on your suggestion, dahlias will rapidly increase in popularity, and contribute, in a few years hence, more to the attractions of the garden than has yet been the case.

POMPON DAHLIA QUEEN OF WHITES.
A distinct variety with pure white flowers.

As my attention is chiefly devoted to the pompon varieties, the question as to whether they are best suited for the exhibition stage or the garden does not greatly concern me, because the varieties, although differing in relative merits, are, with two or three exceptions, equally adapted for both purposes. Evidently the raisers of pompons did not lose sight of the fact that the flower stems should be long enough and of sufficient strength to carry the stems well above the foliage. As the result we have large numbers of varieties that can be depended upon to produce a bright display of colour from the latter part of the summer till the autumn frost, and also to yield plentiful supplies of flowers for competitive purposes. There is a strong objection in some quarters to this section because of the formality of their flowers, and it is not unusual to hear it stated that they are quite unsuited for floral arrangements. This is a mistake, because really charming effects can be produced with them. The arrangements, however tasteful, may not appeal to everyone, because so much depends upon individual taste. The manner in which the pompons are presented to public notice at the exhibitions should not be regarded as evidence of their unsuitability for decorative purposes in a cut state. The arrangements one sees at competitive gatherings are not intended to represent the taste of the exhibitors, but the method of staging the blooms has been adopted as the most convenient for bringing them to the exhibitions, and setting them up on arrival in the comparatively short space of time that is available.

The simplicity of the details by which the most successful results can be obtained in the cultivation of the pompons is, to my mind, a strong recommendation, and especially to those who have not had much experience in dahlia culture. It is necessary to root the cuttings early enough for them to become established in six-inch pots, and be making a vigorous growth by the end of May. The beginning of March is a good time to put the roots in a pit or house, in which a temperature of 60 degrees is maintained. Under the influence of such temperature new growth soon commences, and the cuttings are taken off and inserted singly in small sixties when three or four inches in length. When nicely rooted they are removed to cooler quarters, where they can enjoy a moderate degree of sunlight and a free circulation of air about them. As the pots become filled with roots they are shifted into five or six-inch pots, and a rather rich compost used. The beds and borders in which they are grown are given a moderate dressing of manure, and deeply dug some time during the winter. The first week in June is a suitable time for planting, and where beds and borders are to be wholly devoted to them three feet six inches will be a good distance at which to put them apart.

The number of varieties in cultivation is now so large that the making of a small selection is a perplexing task. Some excellent varieties have recently been mentioned in these pages, but I should like to say that of those included in my collection the following are of special merit: Adela, a pleasing variety, the flowers white, tinted lilac; Bacchus, an old variety, but one of the best, with crimson-scarlet flowers; Claribel, blush, shaded and edged rose-purple; Daisy, bright amber; Douglas, rich maroon-crimson, one of the best of the dark pompons; Ganymede, amber and fawn, shaded rose, a very pleasing combination of colour; Iolanthe, orange-buff, effective; Kitty Barrett, rich yellow, edged scarlet; Nellie Broomhead, lilac; Queen of Whites, one of the best whites; and Tommy Keith, bright crimson, tipped with white.

B. K.

Scilla sibirica.—Of the low-growing blue-flowering bulbous plants so valuable in our outdoor garden in early spring, opinions may differ as to the relative merits of Scilla bifolia, Scilla sibirica, or the chionodoxas. As tastes vary this cannot be decided offhand; but as far as I have seen, in one respect at least, Scilla sibirica has the advantage of the others. This is with regard to its accommodating nature, for in instances that have come under my knowledge it has, under disadvantageous conditions within the London area, made itself at home in places where its brother scilla and the chionodoxas have died out. As a pot plant, too, it is most useful.—W. T.

Bamboos.—The latter half of April and the beginning of May is the most suitable season for lifting, dividing, and replanting bamboos. It is just the time when the plants are starting into fresh growth that the work should be taken in hand. Undoubtedly they thrive most luxuriously in a good depth of stiff loam, which should be well prepared beforehand by trenching and at the same time enriched with well-decayed manure and leaf-soil. Bamboos associate themselves grandly with water, and no doubt the finest effect is obtained when they are grown on the banks of streams or ponds; at the same time, this is not essential, for they thrive equally as well away from it. The most interesting results are obtained by planting them in colonies, or by making a bamboo garden. When the latter is contemplated, a position must be carefully selected, for shelter from the east and north-east winds is necessary, otherwise the plants become browned from exposure, and have a rusty appearance through the summer.—E. C. P.

TRANSPLANTING CELERY.

At the present time hundreds of thousands of small celery plants will be transplanted in various positions and soils. Successful cultivators know exactly how to treat the plants during their early stages of growth so as to eventually procure the best crop. But there are others whose experience in the matter is somewhat limited, and, consequently, they make the common mistake of overgrowing the plants, and, notwithstanding their care and attention, the celery does not turn out really well. The plants look strong enough until they are put out in the trenches, and then they fall apart, and a serious check is given.

Unlike cabbages, which can be cut here and there as they become fit for use, celery in rows must be gathered by commencing at one end of the row and finishing at the opposite. As far as possible, therefore, we must have all plants when finally put out of equal size. To this end a good selection must be made when the seedlings are being transplanted from box to box, or from box to nursery bed. Those seedlings intended for the earliest crops must be subjected to a certain amount of artificial heat, but those for the main crop should have coolframe treatment, if possible.

For the benefit of the inexperienced I will briefly state how I treat my plants. As a result of thin sowing the seedlings are not very crowded, nevertheless, I select those around the outside of the pan, as they are the sturdiest and of about the same size; these are transplanted in a prepared bed of soil made moderately firm. First, I put down a thin layer of rotted manure in a cool frame, and beat it well with a clean spade; then a compost of old fibrous loam, some old mushroom bed manure rubbed through a half-inch mesh sieve, and a small quantity of sand, is laid on to a depth of four inches, and made moderately firm.

The seedlings are pricked out in this bed four inches apart each way, then watered, shaded in bright weather for a few days; afterwards they are freely ventilated, but fully exposed to the light and sunshine; in due course the lights are removed altogether. In the meantime their final quarters are prepared, and when the time comes to put out the plants they are lifted with a good ball of soil and manure attached, and never droop in the trenches. Their progress is steady throughout the season, the sticks being solid and heavy.

Geo. Garner.

A PLEASING GROUP OF ALPINES.

The method of exhibiting alpine plants has altered very considerably within the past ten years. Formerly a group consisted of a collection of small pot-grown specimens, arranged on the flat, with a background of dwarf shrubs, or, in a few cases, a series of pans of saxifragas, sedums, primulas, etc., were arranged; also on the flat staging. But nowadays the traders compete with each other in their efforts to display plants in as natural a manner as possible, and they dispose the dainty specimens in groups on a miniature rock garden. Such exhibits are very pleasing, provided the association of plants is not incongruous. Mr. Clarence Elliott, Seven Hills, Stevenage, has arranged many charming rock garden exhibits at the meetings of the Royal Horticultural Society, and one of these is illustrated in the present issue. Primulas and saxifragas were the outstanding features on this occasion, and they were prettily disposed in informal colonies. It may be worth while to observe that the palms which intrude in the pictures have nothing whatever to do with Mr. Elliott's exhibit, but are part of another display altogether.

A PLEASING ARRANGEMENT OF ALPINE FLOWERS.
Exhibited by Mr. Clarence Elliott at a recent R.H.S. Meeting

OWN-ROOT ROSES.

That some varieties of roses do quite as well upon their own roots as upon any foster stock will be admitted by all observant growers. But to go so far as to say stocks should be dispensed with entirely is taking a most extreme view. It would be more reasonable to use both methods of culture. Even some of our strongest roses are very chary of rooting from cuttings. Take the Austrian and Persian briars, for example; also Lady and Lord Penzance sweet briars, with the strongest of the rugosas. These seem to demand the aid of a foster root before they can be grown with any degree of success. It is the same also with some of the newer hybrid Wichuraianas, not a few of which I have failed to root with any degree of success. On the other hand, perhaps no roses root so freely as Dorothy Perkins, White Dorothy, Delight, Hiawatha, and several more; these even rooting more freely than the manetti and polyantha stocks.

We also find some of the Chinas, and many teas and hybrid teas, root with exceptional freedom, and it is such varieties that can be grown in that way to great advantage. Much time is saved that would be occupied in growing the stocks, besides the year lost while budding. Not the least point in favour of own-root roses is their entire freedom from objectionable suckers.

Very soon a considerable number of excellent cuttings will be available from forced plants of teas and their hybrids. Short pieces of growth, a little more than half-ripened, will root freely if kept close in a compost of loam and sand. The main thing is to keep them quite close for a time. Always select free growers for this purpose, for there can be little doubt stocks are absolutely necessary for some roses, and with the better preparation of stocks now practised the risk of suckers is almost nil. One has only to remember the hundreds of thousands of roses annually worked upon stocks in this country alone to be certain it is essential in many cases. A. Piper.

Pea G. F. Wilson.—This variety is not one of the largest or most handsome, but it is a splendid one for growing in naturally light, dry soils, and in a dry season. It is an old variety, too. I grew peas at one time in a light soil, which sloped very much to the south, and the above-named variety was one of the first tried. Occasionally, of course, we experienced rather dry, hot summers, and the peas suffered more or less, but the one to remain the greenest and most satisfactory at such times was G. F. Wilson. When the summers were wet, however, many pods came quickly.—G. B.

SPRING-FLOWERING SHRUBS

We are reminded at this season of the value of such shrubs that possess the temerity to bloom under somewhat adverse conditions, and while the majority have scarcely resumed activity. The climatic conditions must be bad, indeed, if two or three amongst the rhododendrons fail to unfold their beauty from February onwards, and fine examples of R. nobleanum were noted at Kew during that month. R. barbatum is also a very desirable species, and some idea of its hardy character may be gathered from the fact that in spite of frost and cold winds it blossoms with regularity in February, while its crimson-scarlet colouring is both effective and welcome. A very fine hybrid is seen in R. Shilsoni, which claims R. barbatum as one of its parents, and great brilliance is seen in its crimson flowers; when arranged in bold groups of a dozen or more a fine effect is produced. R. ciliatum gives us delicate pink flowers which change to pure white with age, while it is of a sturdy and compact habit. Need it be said that a sheltered site should be allocated to these rhododendrons, or that they are well worth the labour involved in affording protection with reed mats or evergreen prunings while in flower and during severe or boisterous periods.

The Purple-leaved Plum, Prunus Pissardi, hastens to clothe its naked stems with minute and pure white flowers with the advent of March, and, to my mind, would be well worth growing if this were its only qualification. It is not so, however, and it yields to none amongst shrubs with richly-coloured leafage. Beautiful, indeed, are the delicate pink flowers of P. triloba fl. pl., while another double form of long-lived beauty is seen in P. spinosa fl. pl. The hardy heaths, too, are cheery subjects, being responsible for bright spots in the garden in the early season. Erica carnea rosea and its variety are good examples, while E. codonodes takes the form of a small tree, and may often be seen towering up to a dozen or more feet in height.

One need not dwell upon the merits of Cydonia japonica, but it would be well if other kinds were more freely represented in gardens generally. C. Maulei, in richest scarlet, and its variety alba, also C. cardinalis, are of great merit. The amelanchiers are endowed with graceful beauty and it may perhaps be said are pre-eminent as far as elegance is concerned amongst spring-flowering trees. Further, they are accommodating to a degree, and seem to luxuriate in a variety of positions and soils.

The old Flowering Currant, Ribes sanguinea, has been in full beauty since March 12 here in congested Bermondsey, and its behaviour as a town plant is fully appreciated, and the same applies to the almond tree, which literally clothes itself with its delicate flowers at this season. Experiments made with Pyrus malus floribunda and the double Peach, Amygdalus magnifica fl. pl., have gone to show that they cannot withstand an impure and chemical-laden atmosphere, and they fail after the first season. As so well known, they are a huge success and very desirable in the country. It is impossible to speak too highly of the ornamental cherries, which resolve themselves into a white sheet each season, and by bringing the various forms together we get a beautiful picture. Cerasus pseudo cerasus is very fine, as is also the variety J. H. Veitch, while the double form of the ordinary cherry forms a splendid lawn ornament.

Given a sheltered spot, secure from rough winds and early spring frosts, two or three amongst the magnolias make a brave show in April and early in May, and let us hope that M. stellata and M. Soulangeana will soon enjoy the same popularity and be as extensively planted as the yulan. The more showy and handsome of the shrubby spiræas should be represented in every garden, and, given liberal culture, they yield up a great wealth of flowers. Further, some of the finest blossom in spring, and the same holds good in speaking of the barberries, which are responsible for much beauty and brilliance at perhaps the most attractive period of the year. B. stenophylla, B. concinna, and B. Darwini are good examples. Walter H. Aggett.

CHOICE CAMPANULAS FOR THE ROCKERY.

For furnishing the rockery and creating interest over a long season the dwarf bellflowers are most useful, and, almost without exception, they grow freely and flower abundantly. I need hardly say any yearly attention given them in the way of fresh soil before growth commences, as well as replanting occasionally, well repays the trouble taken. Sandy loam, with an addition of old mortar rubble, and a small quantity of manure, will do much to aid growth, and, naturally, increase the blossoms, as well as maintain the colour of each in its true shade of blue.

For edgings to paths these dwarf campanulas are useful, and produce a fine effect when planted in masses of one variety. Such edgings as these are distinctly more interesting than the ordinary box edging, and do not harbour slugs and snails, as does box, when allowed to grow too large, as is too often the case.

Campanula turbinata grandiflora is a distinct advance upon the ordinary forms, being larger in flower and freer in growth; in colour it is the same, deep blue, and it grows six inches high. C. t. alba is a beautiful white form, difficult to obtain true; four inches high. C. t. Isabel has deep violet-blue flowers, which open quite flat; it is free in growth and flowering, and quite one of the best of rock plants; six inches high. C. pulla is a neat-growing species, three inches high, with dark purple flowers. C. pulloides is a larger form of the above, and a distinct improvement. C. pumila and C. p. alba, the blue and white forms of this dwarf-growing plant, flower most profusely, and grow in hillocks.

C. abietina is a capital alpine plant, with purple flowers; it grows a foot high. C. Allioni bears large solitary blue flowers. C. carpatica is the well-known blue Carpathian bellflower; it grows about six inches high. C. c. alba is a white form, and a pretty companion to the former. C. c. White Star is a new white-flowered form, with handsome blossoms. C. c. Riverslea, gives clematis-like flowers of a rich blue on slender erect stems. C. excisa is a delightful little alpine, three inches high, with funnel-shaped blue flowers. C. Stansfieldi bears pretty blue-violet flowers, and growing but three inches high. C. G. F. Wilson, a fine hybrid, with deep purplish-blue flowers, is six inches high. C. Hendersoni carries a mass of deep cup-shaped flowers, of a violet colour, and is one foot high. C. Hosti grows in a light graceful manner, and has deep blue flowers. C. Profusion is a new hybrid, free in growth, and gives a profusion of mauve-blue flowers in August and September; tender; six inches.

E. Molyneux.

POPPIES AND MIGNONETTE.

Twice during the summer season combined sowings of poppies and mignonette may be made in sunny borders. Both kinds of plants grow and flower freely in such positions, and where the soil is only of very moderate richness. It is a difficult matter for some cultivators to procure a plentiful supply of manure for the flower beds, and many kinds of bedding-out plants require a fairly rich rooting medium if they are to be quite successful. For many years I devoted certain borders in the garden to the two kinds of flowers named, and the result was always satisfactory.

The soil was deeply dug, and, being of moderate richness, manure was not put in. The seeds of both kinds were sown at the same time, they were scattered thinly on the surface broadcast, and then raked in; the first sowing was made in April. I think the prettiest effect was secured by sowing the Shirley poppies; all the flowers were borne above those of the mignonette, and, from a distance, they looked like hosts of butterflies hovering above the bed in a gentle breeze. But another fine effect was secured by the dropping of the seeds of Victoria Cross and other varieties of poppies in separate clumps at a few feet apart, still retaining the mignonette as a groundwork.

In the case of the Shirley varieties, it was not necessary to thin out the young plants, but it is advisable to do so in the case of the large-leaved varieties, so as to provide sufficient light for the full development of the mignonette. All seed pods must be gathered before the seed in them matures and falls on the ground, as, if it does, seedlings will appear where not wanted the next year, and, furthermore, the constant removal of the seed pods ensures a longer flowering period.

The following are lovely varieties of poppies to grow, namely, Miss Sherwood, white, bordered rose; Admiral, white, single, paeony-flowered, scarlet band around the top; Snowdrift, pure white; White Queen, double white; The Mikado, double white, crimson edge; The Cardinal, double, scarlet on white ground; The Tulip, scarlet; The Peacock, scarlet, black zones on each petal.

G. B.

PEACHES AT WOBURN PLACE

The illustration of Peach Libra (p. 165), although well representing that tree carrying four dozen good-sized fruit, is only a fair indication of what peaches growing at Woburn Place are like, in spite of the ungenial soil conditions, as described by Mr. Stevenson.

I was at Woburn Place last year, and thought I never saw peach trees looking better or carrying crops of superior fruit. Mr. T. Stevenson does not agree that out-of-door peach culture is a thing of the past, nor does he make the unfavourable weather an excuse, though this is often advanced by many present-day cultivators.

In addition to the variety named, there were huge crops of Hale's Early, Barrington, Bellegarde, and Princess of Wales peaches, with Humboldt, Pine Apple, Rivers' Early Orange, and Lord Napier nectarines. Mr. Stevenson does not believe in allowing a tree to carry double the quantity of shoots required to provide a full crop or to furnish the wall, but prefers space for the proper development of leaves and wood, and in this manner he obtains maturity, for he knows quite well that is the salient point in producing desirable crops of the finest peaches, even though the trees are but six years planted.

E. M

CHINESE PRIMULAS AT FOREST HILL.

Never have the primulas looked so well at Messrs. James Carter and Co.'s Forest Hill nurseries as this season. When we visited the nursery house after house was filled with plants that were pictures of rude health, models of cultivation, and full of beautiful blooms. Some years ago Messrs. Carter used to flower their primulas earlier in the year, and we have recollections of journeying to the Houston Road Nurseries, Forest Hill, "when the snow lay round about," decidedly "cool," if not "crisp and even." But the ever-increasing demand for seeds of the fine strains here cultivated has made it imperative that every plant shall produce the maximum of those tiny grains that will each reproduce its variety. To secure the largest possible crop a slightly later flowering period has been selected, so that at the end of February and through March, when the sun helps to make the pollen "free," the big batches of plants are at their best. It is, however, a good plan to visit the nurseries as early in March as possible, because as soon as the flowers are fully open the work of fertilisation goes on, assisted by skilful fingers and a camel-hair brush. Every day the flowers are brushed over, and the utmost care is taken to use one brush only for each variety. The effect of regular pollination is soon seen upon the plants, because, having set seed, the blooms quickly fade and fall, hence the grand colour effects produced by the plants soon lose their pristine brilliance. Of course, this is what the seedsman wants, and when the rounded seed vessels set at the base of the green calyx swell up readily in each bloom, then the prospect of a good seed harvest is excellent.

The double primulas are particularly good at Forest Hill. They seed as freely as the single forms, because the doubling is not due to the petaloid character of the stamens, or to the multiplication of petals at the expense of fertility, but to an outgrowth of the true petals from close to the eye, so that while the flowers have a double appearance, and are, for all practical purposes double, they are not so, strictly speaking. This is an advantage, because really double flowers rarely seed freely. Carmine Empress, rich red; Princess of Wales, white, flaked with pink; Double Pink, blush; Double Scarlet, very rich shade; Lilac Queen, a pleasing silvery-lilac; and Snowflake, white, form a set of double primulas remarkable alike for their freedom, usefulness, and beauty.

The "catch of the season" is the new Raynes Park White, a giant single white variety, of wonderful substance, exquisite beauty, the utmost purity, splendid habit, and freedom of flowering. The frilled overlapping petals make up a large bloom, and the blooms make up a perfect truss, surrounded by elegant leafage, so that the variety is a model one in every way. But though this newcomer promises to lord it over his fellows, there are other single varieties of high merit that have certain colour attractions it does not possess, and, after all, we must have variety, even in primulas. For instance, there are the two exquisite varieties named King Edward and Princess May. The former is a grand white variety that appeals to everyone by reason of its bold flowers and large trusses. Princess May is a pink variety of great beauty and freedom, while Holborn Coral gives a delightfully warm shade of coralred that is very effective. White Elaine always attracts attention, as its pure white blossoms are thrown into sharp contrast by the dark stems and leafage. Holborn Blue and Holborn Ruby are two others of great beauty, and deservedly popular for the richness of their colouring.

Turning to the star primulas, there can be no getting away from the fact that notwithstanding the glories of the giant florists' forms, there is a beauty in the more graceful stellate varieties that makes for wide popularity. The amateur with limited conveniences is pinning his faith to this section, and in every establishment where Chinese primulas are grown the star varieties are becoming more largely cultivated year by year. A well-grown plant of either the pink, white, lilac, crimson, salmon, or blue varieties is a picture of loveliness, and set in an ornamental pot, it is a charming ornament for the table or a delightful present for a friend. As you look at the fine batches of these varieties at Forest Hill it is easily understandable that the popularity of the section has advanced by leaps and bounds during the past few years.

PRIMULA SINENSIS RAYNES PARK WHITE.
A giant single white variety, raised by Messrs. J. Carter and Co.

Daphne mezereum.—This is well worthy of a place among the most select of our hardy shrubs, one great point in its favour, apart from its beauty and fragrance, being the early season of the year at which it flowers. There is a good deal of individual variation in the colour of the blossoms, some being of a much richer shade than others. In nurseries the varietal name of rubra is often applied to the best form. There is besides this a variety alba, with white blossoms, which is also represented by a rare double-flowered form. A distinct variety is grandiflora, with blooms of a lilac tint.—W. F.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

CATTLEYA HOUSE.—Plants of Cattleya Trianæ should be examined, and repotted as they pass out of flower, if necessary. They usually commence rooting during the period in which their flowers are developing, and, consequently, many roots will have advanced to a considerable length, it is therefore the more difficult to avoid injury to the roots in the potting process. Every care must be observed when turning the plants out of their pots, and in removing the decayed potting compost. If the potting compost is in a good state of preservation, and the plants only require more root room, it is desirable to use a larger pot without disturbing the old material more than is absolutely necessary. However carefully the operation is done cattleyas and their allied genera suffer more or less from repotting, and with every care and attention it is frequently some time before the plants regain their normal vigour. This is particularly the case with imported plants; the home-raised hybrids appear to be able to recover much more rapidly. In all cases they should be relieved from flowering the first season after repotting. The effects of flowering is very pronounced in a plant that is not well rooted. We find a suitable compost consists of about equal portions of osmunda fibre, peat, and sphagnum moss, a few broken oak or beech leaves, and sufficient sand and broken crocks to render the compost porous.

EPIPHRONITIS VEITCHI.—This charming bigeneric hybrid is now producing its flower scapes. Careful observation is necessary to keep the plants free from thrips and other insect pests, which attack and spoil the flower scapes. This orchid is so easily cultivated, and is so free flowering, that it is worthy of extensive cultivation. As the plants pass out of flower repotting should be attended to. I find it is best to repot annually. New growths are freely produced from the sides of the shoots that have flowered, and as these are produced at varying distances along the stem, it seems difficult to provide a rooting medium without either cutting off these shoots or shortening the old growth. But as roots are freely produced along the stem of the old growths, as well as from the base of the new, there is little difficulty in preparing the plants for repotting. It is best to place several growths together in the same pan, and to select those that are about in the same state of growth for each. See that ample drainage is provided, and use as a potting compost equal portions of fibrous peat and finely chopped sphagnum, with sand and broken crocks added. We find the plants do best on the stage in a warm intermediate house.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

GLOXINIAS.—The present time affords a favourable opportunity for raising further batches of gloxinias, and other similar stove subjects usually raised from seed. For this purpose have in readiness some shallow pans or boxes, which must be provided with ample drainage, and both drainage and pans must be thoroughly clean and dry. Fill these within half an inch of the rim with finely sifted material composed of loam, leaf-soil, and sand. After the surface has been made even a thorough watering may be applied, and the pans be allowed to drain for an hour or two previous to sowing the seed, which must be sown thinly and evenly. With the finer seeds it is advisable not to apply any covering of compost, and a very fine sprinkling of silver sand will, in most cases, be sufficient. The pans should afterwards be placed in the propagating case and covered with glass. Any older specimens of gloxinias that are nicely started into growth may be repotted as the opportunity occurs. The tubers started in January, as advised in a previous calendar, are now showing abundance of flower buds, and will need regular applications of liquid manure and soot water; a top-dressing of bonemeal at this stage will also be found to afford the plants much assistance.

CLIMBERS will need regular attention from now onwards, and the shoots must be regularly tied into position. Remove all weak and undesirable shoots. Climbers must not be allowed to ramble at will, or much injury will be done to the other occupants by the exclusion of light. Where old permanent borders exist they must be renovated from time to time.

CROTONS AND DRACÆNAS, which were notched and mossed as recommended in a previous calendar will now be ready for removal from their parent plants; this, however, must be done with extreme care if no loss of foliage is to be experienced. It is advisable to separate the tops by cutting the stems halfway through first, and, after two or three days, finally removing the tops and potting them up. Where bottom heat is available they may be plunged for a few days until root action is vigorous. A cucumber house is also an ideal place for starting the tops into growth after potting. Apply a good shade during hot sunshine, and occasionally syringe overhead during the day. Established crotons are now making rapid progress, and those who desire highly-coloured specimens for exhibition purposes must now afford the plants plenty of light, and place them as near the glass as possible without injury to the foliage. As the pots become filled with roots the colour of the foliage grows richer, and it may be further improved by frequent regular applications of some approved fertiliser, used in accordance with instructions.—John Donoghue, Bardon Hill Gardens.

THE FLOWER GARDEN.

SHRUBBERIES.—All evergreen shrubs may be transplanted now with safety. A good ball of earth should remain attached to the roots, and its size must be determined by the size of the tree or shrub to be lifted. The operation needs great care, so that the ball is not broken; otherwise failure may occur. After being placed in its new position and the soil filled in, a good watering should be afforded. If the surface is left in a hollow formation watering can be readily accomplished, and the roots will obtain the full benefit of the water. A good mulching proves beneficial in conserving the moisture. The plant should be made secure against the winds either by the use of stakes or wires. Should there be a spell of dry weather the freshly-planted deciduous shrubs will require watering, especially those which have been planted since Christmas. Shrubs planted early in autumn usually make sufficient roots to take care of themselves; yet an occasional examination is advisable. Stakes, ties, and all supports should be thoroughly examined, and, where necessary, made good.

FORSYTHIA SUSPENSA should be pruned immediately the flowers are over. It is one of the most beautiful of our early-flowering shrubs, and well repays any extra attention bestowed upon it. The weak, thin growths may be cut out, and the stronger shoots cut back to within a few inches of the older wood. This will encourage the plant to make good growths for next spring flowering. The sucker growths which often occur round the stems of lilacs should be removed, or they will eventually spoil the plant. The double gorse should be pruned hard after flowering if the plants are inclined to become leggy and untidy.

GUNNERA MANICATA AND G. SCABRA are two of the noblest plants we have for streamsides, and should be planted as soon as growth commences. Their cultivation is exceedingly simple, providing they are planted where the roots can quickly reach the water. A position on the extreme edge of the water should be afforded them. Established plants which have had their winter covering removed must yet be protected by a covering of mats when the nights are frosty, for if the young growths are damaged by frost they do not recover, and the edges of the leaves look untidy all through the season. By removing the flower-heads early in the season larger leaves are obtained, and a slight dressing of nitrate of soda given occasionally when the plants are in full growth is beneficial.

HERBACEOUS BORDERS.—Now that the majority of the plants are well above ground, and can be plainly seen, the surface of the soil should be frequently stirred with the hoe. Great care must be exercised when working near clumps of late-flowering liliums, gladioli, Galtonia candicans, and such bulbous plants, which have not yet appeared above the surface. The incarvilleas are not yet showing growth; therefore any weeding required must be accomplished by hand. The growths of Michaelmas daisies should be thinned out, leaving sufficient to form a good clump and allowing each growth enough room to develop properly. This advice also applies to helianthuses, solidagos, heleniums, and other plants of similar habits.—E. C. Pooley, Gnaton Gardens.

FRUITS UNDER GLASS.

EARLY VINERY.—The bunches should now be finally examined, and any portions crowded should be thinned out carefully, while any stoneless or misshapen berries should also be removed. Carefully loop up any large shoulders. In the case of old or permanent vines that have reached the top of the roof, nothing more will be necessary beyond pinching the laterals about every other week. If the vines are young and have not reached the top, tie the main rod carefully, and when it has reached the desired length it may be stopped in order to give strength to the lower branches; but after once stopping it should be allowed to go on again in order to encourage the uppermost growths. Guard against mealy bug and mildew. See that the roots do not lack moisture; damp down very thoroughly several times daily, and maintain a steady temperature of from 65 to 75 deg.—the latter, of course, with sunshine. A little air should be given by means of the top ventilators first thing in the morning, and as the temperature rises give more air.

ORCHARD HOUSE.—The trees in this house will now be in full bloom, and great judgment is required to keep an even temperature. Keep the ventilators closed on the windy side, and open the others and the door wide during sunshine. Examine the trees about the middle of the day, and give them a sharp tap or shake to distribute the pollen. On a very bright, sunny day a gentle spraying about 2.30 p.m. will give the trees great assistance. As soon as the blooms have set the house should be fumigated, even if no aphis is present, as cherries and peaches are liable to attack at this stage, following this the next day with a good sharp syringing, and, if need be, a good watering. Early pears grown in these structures will need much water, and unless they obtain it they very quickly drop their fruits. Cherries in pots carrying good crops should now be topdressed with some good compost, and be watered at least twice a week with liquid manure, and be well syringed twice daily; and those growing in the border must likewise have frequent manurial waterings, and the points pinched out if growing freely. I like to do all the pruning with the thumb and finger.

STRAWBERRIES.—As soon as the early crop is finished clear the plants out at once, and, if not wanted, throw them away. I think it always best to throw the earliest lot away, as those forced later will be found much more serviceable for other purposes. Give the shelves a good scrubbing before more plants are placed thereon. As subsequent batches are introduced less forcing will be required, and as each batch approaches maturity a lower temperature should be employed. The latest batches should be kept cool and airy.—W. A. Cook, Leonardslee Gardens.

EXHIBITIONS AND MEETINGS.

Cornwall Daffodil and Spring Flower Society.

This society, which is the oldest of those devoted to the daffodil, having been incorporated sixteen years ago, has for patronesses her Majesty Queen Mary and her Majesty Queen Alexandra, while among the names of the vice-presidents are to be found the Earl of Mount Edgcumbe, Sir A. P. Vivian, K.C.B., the Viscountess Falmouth, and Mr. T. A. Dorrien-Smith, so that it is under distinguished patronage. From its inception the spring shows of this society have attained a high standard of excellence, and the present exhibition, which was opened in the great Market Hall at Truro on April 4, was fully equal to the best of its predecessors. The entries were large, and the competition in almost all classes was exceedingly keen, and many of the exhibits were notable for their excellent quality. Ever since the formation of the society the Hon. John Boscawen has been the hon. secretary, and under his skilful management and invariable courtesy all the arrangements are carried out to perfection, there never having been a single complaint. The band of the Royal Marines played during the afternoon in a portion of the hall partitioned off, and delighted the visitors, while those desirous of closely inspecting the flowers were not incommoded. During the afternoon the attendance was very large, all parts of England and the Metropolis contributing to the total, while the county of Cornwall was influentially represented. Unfortunately the past March, with its absence of sun and continued east winds, was much against the early-flowering shrubs, which made practically no advance through the whole month, with the result that some varieties which usually appear were conspicuous by their absence.

Of the daffodils the greatest interest centred in Class 2, for thirty varieties, in commerce or not in commerce. In this class numerous seedlings of high merit were staged, though the majority were numbered and not named. First prize was won by Mr. T. C. Williams, and among the notable flowers were 317; with white petals and spreading orange-red cup; 81, white petals and yellow saucer-shaped cup edged with orange; 11, an enormous bicolor incomparabilis; 261, bright golden trumpet; 289, primrose petals, spreading yellow cup, edged with orange-scarlet; 260, with massive petals and flat citron cup edged with orange. Mr. P. D. Williams was a very close second, two of his most striking varieties being Medusa, white petals and glowing crimson-orange cup, a twin flower; and Robespierre, with orange-scarlet cup. For thirty varieties of daffodils in commerce, Mr. E. H. Williams was first, and in his stand King Alfred, Cœur de Lion, Victoria, Redbreast, Beacon, White Queen, and Lady Margaret Boscawen were very fine.

In the next nine classes the price of the bulbs was limited to 10s. Six magni-coronati: First prize, Lady Margaret Boscawen. Six medio-coronati: First prize, Mr. A. Blenkinsop. Six Leedsi: First prize, Miss Clarice Vivian. Six parvi-coronati: First prize, Miss C. Vivian. Fifteen distinct varieties: First prize, Mr. H. G. Hawker.

Finest bloom magni-coronati: First prize, Miss Nowell Usticke, with King Alfred; second prize, Mr. R. S. Nowell Usticke, with Rev. D. R. Williamson. Finest bloom medio-coronati: First prize, Miss L. Williams, with Lady Margaret Boscawen; second prize, Mr. A. Blenkinsop, with Homespun. Finest bloom parvi-coronati: First prize, Miss Clarice Vivian, with Armorel; second prize, Mr. R. S. Nowell Usticke, with Blood Orange, Finest bloom poeticus: First prize, Miss Clarice Vivian, with Horace; second prize, Miss Nowell Usticke, with Homer. Three doubles: First prize, Col. Nowell Usticke. Fifteen distinct varieties: Equal first prizes, Lady Margaret Boscawen and Mr. A. Blenkinsop. Finest bloom magni-coronati in commerce: First prize, Mr. E. H. Williams, with King's Norton; second prize, Mr. A. Blenkinsop, with Van Waveren's Giant. Finest bloom medio-coronati in commerce: First prize, Mr. E. H. Williams, with White Queen; second prize, Miss Clarice Vivian, with Bernardino. Finest bloom parvi-coronati: First prize, Mr. E. H. Williams, with Incognita; second prize, Col. Nowell Usticke, with Blood Orange. Finest bloom poeticus: First prize, Col. Nowell Usticke, with Dante; second prize, Mr. E. H. Williams, with Homer.

Three finest blooms of magni-coronati, not in commerce: First prize, Mr. J. C. Williams, with three fine flowers. Three finest blooms of medio-coronati, not in commerce: First prize, Mr. P. D. Williams, with 92, a clear yellow; Elizabeth, primrose petals and deep yellow cup; and Robespierre, primrose petals and orange-scarlet cup. Three finest blooms of parvi-coronati, not in commerce: First prize, Mr. P. D. Williams, with Medusa, a beautiful, though not over large flower, with white petals and orange-scarlet cup, borne two on a stem; Liberty, white petals and flat yellow-cup; and 717, white petals, spreading orange-scarlet cup. Ten distinct varieties, any section: First prize, Mr. C. Bewes.

Three bunches of anemones: First prize, Mr. R. Fox. One bunch Anemone fulgens: First prize, Mr. T. B. Bolitho. Three polyanthus plants: First prize, Lady Margaret Boscawen. Three primrose plants: First prize, Miss Danbuz. Twelve varieties of hardy unforced spring flowers: First prize, Mr. T. B. Bolitho, with Fritillaria meleagris, Sanguinaria canadensis, Anemone blanda, Erythronium Johnsoni, Tulipa præstans, Muscari botryoides album, Iris bucharica, Myosotidium nobile, Iris orchioides, Caltha platypetala, Tulipa saxatilis, and Fritillaria imperialis. Six varieties of hardy unforced spring flowers: First prize, Mr. T. B. Bolitho, with Erythronium revolutum, Muscari botryoides, Muscari Heavenly Blue, Tulip Keiser Kroon, Caltha platypetala, and Myosotidium nobile.

Collection of hardy spring flowers arranged as a rockery: First prize, Miss Waterer, with Iris tingitana, Corydalis cheilanthiphia. Viola gracilis, Parochetus communis, Lithospermum prostratum, Muscari conicum, Saxifraga Rhei, and other rock plants. Three bunches single violets: First prize, Hon. H. F. Trefusis. Three bunches double violets: First prize, Capt. W. Tremayne. Three bunches single violets, one variety: First prize, Hon. H. F. Trefusis. Three bunches double violets, one variety: First prize, Capt. W. Tremayne. Six vases of roses: First prize, Mrs. Messer Bennetts. Three vases of roses: First prize, Mrs. Messer Bennetts. Three vases of carnations: First prize, Mr. C. Bewes.

Flowering Shrubs.—Finest plant of rhododendron in flower: First prize, Mr. E. B. Beauchamp. Best group of rhododendron blooms: First prize, Mr. D. H. Shilson, the stand containing R. Iverianum, R. arboreum roseum crispum, Beauty of Tremough, Thompsoni, Duchess of Cornwall, R. barbatum, R. argenteum, Gill's Triumph, and R. arboreum giganteum. Six trusses of rhododendrons, cut from plants out of doors: First prize, Mr. J. C. Williams. Three trusses of large-leafed rhododendrons: First prize, Mr. D. H. Shilson. Six cut trusses of rhododendrons under glass: First prize, Mr. R. Fox. Finest rhododendron truss out of doors: First prize, Mr. Robert Fox. Finest truss of hybrid Sikkim rhododendron out of doors: First prize, Mr. J. C. Williams. Finest truss of rhododendron under glass: First prize, Mr. E. J. P. Magor. Three large jars of sprays of outdoor rhododendrons, three varieties: First prize, Mr. Robert Fox, with R. Shilsoni and two seedlings. Six cut blooms of camellias under glass: First prize, Mr. J. C. Danbuz. Three large jars of sprays of outdoor camellias: First prize, Mr. R. Fox. Three vases acacia, out of doors: First prize, Mr. Charles Hext, with A. dealbata, A. longifolia, and A. ovata. Three vases of acacias, under glass: First prize, Mr. J. H. N. Watson, with A. Drummondi, A. albicans, and A. longifolia magnifica.

Twenty varieties of outdoor, unforced, hard-wood flowering shrubs or climbers: First prize: Mr. T. B. Bolitho, who had Andromeda japonica, Polygala Dalmasiana, Chorizema Lowi, Cerasus Watereri, Cydonia Simoni, Magnolia stellata, Lapageria rosea, Jasminum primulinum, Erica lusitanica, Clianthus puniceus, Chorizema cordatum splendens, Magnolia conspicua, Prunus pendula, Euryops virgineus, Boronia heterophylla, Pernettya ciliaris, Embothrium coccineum, Skimmia Fortunei, Camellia reticulata, Boronia megastigma. This was a remarkable good class. The Rev. A. Boscawen and Mr. R. Fox were placed equal second, but there was very little between their exhibits and the first prize stand. Six varieties of outdoor unforced hardwood flowering shrubs and climbers: First prize, Lady Margaret Boscawen, with Pyrus Maulei, Clematis indivisa lobata, Senecio petasites, Grevillea rosmarinifolia, Ceanothus rigidus, and Jasminum primulinum.

Awards of merit were given to Mr. C. Hext for Rhododendron trebianum, to Mr. J. C. Williams for a rhododendron seedling, to the Rev. A. Boscawen for Erica melanthera, to Mr. R. Gill for the Himalayan Primula Winteri, to Messrs. R. Veitch and Son for hybrid gerberas, to Mr. R. Fox for Rhododendron Lady Alice Fitzwilliams and R. Keysi, and to Mr. P. D. Williams for Shere Khan. Cultural commendations were awarded to Mr. G. Reuthe for Rhododendron intricatum, to Mr. E. Magor for Rhododendron Lindleyi, and to the Rev. A. Boscawen for Acacia diffusa. A first class certificate was given to Narcissus Lemon Star, exhibited by Messrs. Cartwright and Goodwin. The nurserymen's stands were very bright, and added much to the attractions of the show. Miss Josephine Gundry, F.R.H.S., exhibited a selection of beautiful water-colours of gardens and flowers which were much admired.

Royal Caledonian Horticultural Society.

The spring show of this society was held in the Waverley Market, Edinburgh, on April 5 and 6. Notwithstanding the cold, sunless weather experienced for several weeks previous to the show, there was an excellent display, especially of trade exhibits, and the spacious hall looked bright with colour, though the effects of the deficient sunshine was apparent in the case of many things.

GARDENERS AND AMATEURS.

For the group of miscellaneous plants, arranged in a space of 15ft. by 10ft., on the floor, there was only one competitor, Mr. Geo. McKinna (gardener to Sir Robert Usher, Bart., of Norton, Ratho), and he was awarded the first prize. For the group of orchids arranged in a space of 12ft. by 6ft., Mr. J. Smith (gardener to R. Brooman-White, Esq., of Arddarroch), was the only entrant. The group was a very fine one, and Mr. Smith was awarded the first prize, along with the Sander Cup, which has to be won three times before it becomes the property of the competitor. For four stove or greenhouse plants Mr. A. Smith (gardener to Provost Ballantyne, The Neuk, Peebles), was first; and Mr. A. McMillan (gardener to the Earl of Home, Douglas Castle), second. For six plants in bloom (exclusive of hyacinths and tulips), Mr. G. McKinna was first, and Mr. J. Pearson (gardener to Mrs. Bickmore, Beechwood, Murrayfield), second. Mr. D. Kidd (gardener to Lord Elphinstone, Carberry Tower, Musselburgh), was first for greenhouse rhododendrons, and the principal prizewinners in the other plant classes were Messrs. McKinna, McMillan, J. Thom (gardener to Mrs. Hutchison, of Carlowrie, Kirkliston), W. G. Pirie (gardener to C. W. Cowan, Esq., Dalhousie Castle, Bonnyrigg), whose alpines were very fine, G. D. Kerr (gardener to Hon. Mrs. Baillie Hamilton, Langton, Duns), J. McIntyre (gardener to Sir John Murray, Challenger Lodge, Edinburgh), P. R. Hills (gardener to Sir George

Bullough, Kinlock Castle, Isle of Rhum), W. J. Galloway (gardener to Mrs. Dewar, Dryland House, Edinburgh), and J. Cossar (gardener to Miss Watt, Spott House, Dunbar). The gold medal offered by the Royal Dutch Bulb Growers' Society for three pans of hyacinths, was won by Mr. J. Gibson (gardener to the Duke of Portland, Welbeck Abbey, Notts).

In the cut flower classes, Mr. W. G. Pirie was first for twelve bunches narcissi, Mr. J. R. Hills first for 24 roses, and Mr. D. Kidd first for twelve roses. Mr. J. Wilson (gardener to Sir John Gilmour, Bart., of Montrane, Leven), was first for twelve Gloire de Dijon roses, and Mr. J. Pearson first for twelve Marechal Niel roses, while Mr. J. R. Hills was first for twelve of any other variety. In the other cut flower classes the chief prize-winners were Messrs. A. Brydon, Innerleithen, Gibson, McMillan, Kidd, and A. Johnstone (gardener to Miss Gillespie, Hay Lodge, Edinburgh).

For a decorated dinner table, 10ft. by 5ft., Mr. John Hood (gardener to T. G. Bishop, Esq., Dalmore, Helensburgh), was first, and Mr. D. Kidd second.

For the collection of six distinct kinds of vegetables, Mr. Gibson, Welbeck, was first; Mr. R. Stuart (gardener to the Earl of Lauderdale, Thirlestane Castle), second; and Mr. Geo. McKinley (gardener to the American Ambassador, Wrest Park, Beds), third. For a collection of salad plants, Mr. Gibson was first, and Mr. McKinley second. In the other vegetable classes the principal prizes were won by Messrs. Gibson and McKinley.

In the plan competition for under-gardeners there were four entries. The problem is to lay out to the best advantage an area of about sixteen acres, in pleasure ground, kitchen garden, etc., and the competitors are supplied with a small sketch plan, giving the outlines of the ground and its contours. The first prize was awarded to Mr. Charles Wilken, Erskine House Gardens, Renfrewshire; the second to Mr. J. W. Forsyth, Fairburn House Gardens, Muir of Ord; and the third to Mr. E. W. Fuller, Heveningham Hall Gardens, Saxmundham, Suffolk.

NON-COMPETITIVE EXHIBITS.

The largest of these was that of Messrs. Dickson's and Co., Edinburgh, and it consisted of a large group of Pink Pearl rhododendron, interspersed with standard Wichuraiana hybrid, and other roses, and other plants, and they also had two large circular groups of their seedling amaryllis (hippeastrums), of which they make a speciality (gold medal).

Messrs. R. B. Laird and Sons, Lim., Edinburgh, had a very artistic exhibit in virgin cork, with rhododendrons, azaleas, Japanese maples, and other plants

Messrs. Cunningham, Fraser, and Co., Edinburgh, had hybrid rhododendrons as the leading feature of their exhibit, and they also showed choice alpines (silver-gilt medal).

Messrs. W. Cutbush and Son, London, had a nice exhibit of hardy plants, amongst which were several novelties, such as Rhododendron intricatum, and a number of interesting alpines (silver-gilt medal).

The firms who made narcissi the leading feature were Messrs. Barr and Sons, London (silver-gilt medal); Messrs. Hogg and Robertson, Dublin (gold medal); and Mr. J. A. Cooper, Lissadell (silver-gilt medal). Messrs. Hogg and Robertson had also a fine lot of St. Brigid anemones, and Messrs. Barr had some choice alpines. Messrs. Dobbie and Co., Edinburgh, had a nice collection of narcissi, hyacinths, and tulips (silver medal).

Mr. H. N. Ellison, West Bromwich, had choice ferns, hybrid gerberas, and hybrid freesias (silver-gilt medal), and Messrs. John Forbes, Hawick, Lim., had primulas, carnations, violas, various alpines, and florists' flowers (silver medal). Mr. David King, Osborne Nursery, Edinburgh, staged a large display of narcissi, tulips, ferns, palms, etc. (silver-gilt medal), and Dr. McWatt, Duns, exhibited a large and very choice collection of primulas (silver-gilt medal).

Messrs. Todd and Co., Edinburgh, contributed a unique exhibit of bouquets and baskets of carnations, to the exclusion of all other flowers, such novelties as Empire Day, British Queen, Rex, Regina, and Crimson Glow, etc., being used. In view of the carnation being the flower chosen by her Majesty for the Coronation bouquet, this exhibit attracted a good deal of attention (gold medal).

Messrs. Young and Co., Hatherley, Cheltenham, contributed some fine perpetual-flowering carnation novelties, including Duchess of Devonshire, Hon. Audley Neeld, J. W. Riley, Gladwys, Rose Doré, etc. (silver medal); and Messrs. J. and A. Glass, Edinburgh, had also a nice lot of these, Crimson Glow being conspicuous (silver-gilt medal).

Messrs. Storrie and Storrie, Glencarse, Perthshire, staged primulas, hybrid cinerarias, etc.; Messrs. Bakers, Wolverhampton, alpines; Mr. D. McLeod, Chorlton-cum-Hardy, orchids; and Mr. J. E. Sadler, Newbury, orchids.

Messrs. Ransomes, Sims, and Jefferies, Lim., Ipswich, had a very fine exhibit of motor and other lawn mowers, lawn sweepers, verge cutters, etc., and Messrs. Alex. Shanks and Sons, Arbroath, also showed lawn mowers, etc.

The only new plant certificated was a hybrid Indian rhododendron (R. Dalhousiamum seedling x R. Nuttalli), exhibited by Mr. D. Macdonald (gardener to Mrs. Currie, Trinity Cottage, Edinburgh). A first-class certificate was awarded to it.

Bournemouth Spring Show.

APRIL 4 and 5.

The fourth annual spring show was held in the Winter Gardens on the above dates. The general verdict was that it far surpassed any spring show previously held at Bournemouth. The competitive classes were well filled with produce of a very high order of merit throughout. The non-competitive contributions were also extremely fine and representative. Those from Messrs. James Veitch and Sons, London, which included beautiful specimens of amaryllis, nepenthes, hydrangeas, primulas, and orchids; Messrs. Charlesworth and Co., who had orchids; Messrs. Cypher and Son, Cheltenham, orchids; Messrs. Stuart Low and Co., orchids and tree carnations; Messrs. Sutton and Sons, primulas and cinerarias; and Mr. Maurice Prichard, Christchurch, a model rockery exquisitely furnished with alpine and other plants, were very prominent features of the exhibition. These exhibits were not small ones; that of Messrs. James Veitch occupied about fifty feet run of tabling, and the others were also very large.

COMPETITIVE EXHIBITS.

The principal class was that for a group of miscellaneous plants in a space twelve feet by eight feet. The Park Nurseries (manager, Mr. F. W. Welch) secured premier position; the group was a most charming one, lightly arranged, the colours harmonising well. A very fine rose, freely flowered, occupied the centre; begonias, salvias, coleuses, liliums, azaleas, deutzias, lilacs, mignonette, and spiræas were the principal flowers used. Messrs. G. Watts and Sons, Bournemouth, were awarded second prize. The centre was very light and graceful; a fine Magnolia stellata was placed there, and other notable plants were rhododendrons, orchids, spiræas, azaleas, laburnums, hyacinths, with lovely plants of double violets in pots dotted in as an edging.

Mr. R. Thurston (Miss Steel) had the best table decoration, Mr. C. Ball and Miss Taylor being second and third respectively. Mr. T. K. Ingram, of Parkstone, Dorset, scored in the two classes for six Azalea mollis and an indica respectively. Mr. Usher, gardener to Sir Randolph Baker, Bart., M.P., was placed first in the class for twelve pots of narcissi. He had Madame Plemp (2), Leoni, Madame de Graaff, Barri, Golden Spur, Barri Conspicuus, Glory of Leiden (2), Mrs. Langtry, Emperor, and Horsfieldi. Mr. Pearce, gardener to Mrs. Ormond, was a close second, having fine Sir Watkin and Maximus in his collection. Mr. T. K. Ingram was third, and first for six pots of Polyanthus narcissi, with Aspasia, Triumph, Elvira, Ideal, Klondyke, and Irene; these were really splendid pots of plants. Second honours went to Messrs. G. Watts and Sons, who staged fine examples. The latter were well to the front in the class for twelve hyacinths. Grand Maitre, Marie, Czar Peter, King of Blues, Paix de l'Europe, Moreno, Lady Derby, Lord Balfour, Charles Dickens, Queen of Blues, and Mimi were even and good. Mr. Ingram came a close second, having King of the Blues, Jacques, Moreno, and Enchantress exceptionally fine. The Park Nurseries were third. Mr. Ingram scored with lily of the valley, being followed by the Park Nurseries and Messrs. Watts for second and third places respectively. The Park Nurseries had the best twelve tulips in pans not exceeding 7½ inches in diameter. Joost van Vondel, Queen of the Netherlands, Pink Beauty, and El Toreador were finely developed. Messrs. Watts and C. Pearce were second and third respectively.

Mr. Usher again scored in the class for a collection of narcissi, eighteen distinct varieties. Lucifer, Sir Watkin, Horace, White Lady, Victoria, Emperor, Madame Plemp, Queen of Spain (pretty), Glory of Leiden, King Alfred, and Madame de Graaff were the best. Second honours went to Mr. Ingram, Henry Irving, Glory of Leiden, and Victoria being very good; Messrs. Watts were third.

For the best five blooms of narcissi magni-coronati, Glory of Leiden won for Mr. Northway; and Sir Watkin won for the same exhibitor in the class for five blooms, medio-coronati. Mr. T. Squire, of Wimborne, was awarded first prize in the group class, the space occupied being nine feet by six feet; schizanthuses were fine in this group. Mr. Heath, gardener to Mr. G. G. Russell, had the best six pots of narcissi, Mr. Pearce being second, and Mr. George Garner third. Mr. Heath had the best three pots of Polyanthus narcissi. Mr. Pearce won in the class for six hyacinths, Mr. Garner being second and Mr. Heath third. Mr. Garner had the best six pots of tulips, Keizer Kroon, Duchesse de Parma, and Joost van Vondel being very fine. Mr. Pearce was second. Mr. Barge, gardener to the Rev. C. H. Burrows, was awarded first prize for six pots of cyclamen. Messrs. Usher, Heath, and Pearce were very successful exhibitors in the classes for spiræas, cinerarias, primulas, deutzias, mignonette, and zonal pelargoniums.

AWARDS TO TRADE EXHIBITS.

Gold medals were awarded as follows: To Messrs. Sutton and Sons, primulas and cinerarias; Messrs. Charlesworth, orchids; Messrs. J. Veitch and Sons, Chelsea, miscellaneous plants; Messrs. J. Cypher and Sons, orchids; Messrs. Stuart Low and Co., orchids and tree carnations; Mr. Chamberlain, floral designs; Mr. Maurice Prichard, rockery plants. Silver medals: Mr. G. H. Rolls, orchids; and to Mr. W. C. Clark, who had a fine specimen of Dracæna atropurpureum (very scarce). The children's section was a charming one.

Croydon Gardeners' Association.

At the recent fortnightly meeting of this society Dr. J. Augustus Voelcker gave a highly instructive lecture on "The Influence of Physical Conditions upon the Cultivation of the Soil." Mr. J. J. Reid presided over a large audience.

Dr. Voelcker stated in his opening remarks that in defining the word soil we understand it to be an element that primarily holds up the plant and supplies it with food. It is composed of small particles of rock, which has been reduced to its present degree of fineness by the action of water and air. Other agencies, such as earthworms, are helpful in disintegrating these small particles and making the soil fertile. The top soil is darker in colour, and contains more nitrogen than the subsoil, but in the undersoil we find more potash. Soils vary considerably in their texture, the two extremes being sand and clay. Dr. Voelcker, with diagrams,

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

illustrated how these soils are composed, and explained why a sandy soil loses its moisture quicker than clay, which is owing to the larger particles of sand, providing larger channels for the passage of air, but these channels filled with air will not allow moisture to evaporate from the surface so rapidly as clay soils will do. The two great forces at work with soils are gravitation, by which method moisture descends through the soil, and capillarity or a drawing-up power from below. In sand the former force goes on more rapidly owing to the bigger particles allowing the moisture to drain away, the second force being considerably deterred by these bigger particles, and greater air interspaces. In clay soil exactly the opposite takes place, hence we find clay becomes waterlogged. Sandy soil more quickly takes up heat, and loses it as readily owing to the same action as water descending and rising. The lecturer pointed out that what the cultivator has to remember in dealing with soil is, in the case of light soil, he must consolidate, and with heavy soil he must open it. These can both be accomplished by the same means, viz., cultivation, for in the former nitrogenous substances can be incorporated with the soil, binding it together, and in clay or heavy land lime is best mixed with the soil to loosen the fine particles. Frost acts upon heavy land in the same way as lime, so that trenching clay land before frost sets in is highly advantageous. Fine tilth is the great principle in the cultivation of the soil, for it converts the food stored up in the soil into a condition that renders it available for the plants. Dr. Voelcker's remarks were followed with the keenest attention, and so engrossed did he become in his subject that the time slipped quickly by leaving very little for the usual discussion. However, a few questions were asked, and the lecturer's replies embodied further useful information. Each member of the audience no doubt was fully alive to the practical part of cultivating the soil, but, as the lecturer remarked, he would be doubly benefited now by having an explanation of why he did it.

A hearty vote of thanks was accorded to Dr. Voelcker, and to Mr. J. J. Reid.

Reading Gardeners' Association.

The usual fortnightly meeting was held in the Abbey Hall, Reading, on Monday, April 3, Mr. F. Townsend occupying the chair, and there was again a large attendance. Mr. Alderman Parfitt, owing to indisposition, was unable to be present.

The lecturer for the evening was Mr. T. Wilkinson, of The Gardens, Tyntesfield Park, Bristol (representative from the Bristol and District Gardeners' Association), his subject being "Grapes." Mr. Wilkinson is a prominent grower of the luscious fruit in the west, and his remarks were listened to with great attention by the assembled audience. Mr. Wilkinson explained at the opening that it was not his intention to give a lengthy paper, his object being rather to provoke discussion, whereby much useful information is certain to be diffused.

The paper, though brief, was exceedingly lucid and practical. The construction of houses and preparation of borders (here the lecturer was emphatically against deep borders), being first referred to. Afterwards manuring, watering, stopping, thinning, ventilation, cracking, shanking etc., were dealt with. Mr. Wilkinson had every reason to be satisfied that the object he had in view was realised, for quite the best discussion which has taken place this session followed the close of his remarks, the lecturer being closely plied with the questions, which he answered readily and to the point.

On the proposition of the Chairman, seconded by the Vice-chairman, a hearty vote of thanks to Mr. Wilkinson was carried with applause.

Royal Horticultural Society.

(Continued from page 278.)

spikes, Odontioda Vuylstekeæ, O. Gattonense, Dendrobium Brymerianum, Odontoglossum Queen of Gatton, and Chysis Langleyensis.

Odontoglossum Prince Albert, brown spotted on a blush ground, was submitted by Mr. Day, gardener to H. S. Goodson, Esq., West Hill, Putney.

Mr. Stables, gardener to De Barri Crawshay, Esq., Rosefield, Sevenoaks, brought forward Odontioda Rosefieldiensis (A.M.)—O. triumphans crossed with Cochlioda Noetzliana; Odontoglossum crispum Princess, O. illustré, O. Vulcan, and the showy O. Leonidas.

Odontoglossum triumphans and Oncidium concolor were very conspicuous in the exhibit arranged by Messrs. Stuart Low and Co., Enfield; Cattleya Schröderæ, Cymbidium Woodhamensis, and Renanthera Imschootiana were other good things.

From Messrs. Mansell and Hatcher, Rawdon, Leeds, came Lælio-cattleya Wellsiana alba, Brasso-cattleya Mrs. M. Gratrix, Odontoglossum Dora, O. Rolfeæ, O. Ossulstonei, O. Pescatorei virginale, and other lovely things.

Messrs. Charlesworth and Co., Haywards Heath, presented a very beautiful exhibit of orchids, odontiodas, oncidiums, and odontoglossums figuring largely. Of the former, O. Cassiope, O. Bohnhofiæ, O. Bradshawiæ, and O. Charlesworthi were fine; other splendid things were Odontoglossum Ossulstonei The Shrubbery var. (F.C.C.), with sixteen splendid flowers of rich maroon, purple, and white colouring; the quaint Selenopedium Lindeni, Cattleya Endora, Bulbophyllum virescens, and Brassia brachiata.

Messrs. Armstrong and Brown, Tunbridge Wells, set out their plants among maidenhair ferns, and disposed them thinly. Notable things were Brasso-cattleya Thorntoni, Odontoglossum excellens, Lælio-cattleya eximea, L.-c. Ernesti, and a number of interesting seedling cypripediums.

Messrs. Sander and Sons, St. Albans, exhibited Odontioda Vuylstekiæ finely, and also presented Cattleya Schröderæ, Odontoglossum Pescatorei, Brasso-cattleya Chas. Mason, Cypripedium Merlin magnificum, Scuticaria Hadweni, and other beautiful and interesting orchids.

Messrs. W. B. Hartland and Sons, Ardcairn, Cork, showed Cattleya Schröderæ, Odontoglossum crispum, and Cypripedium Curtisi in some quantity.

DAFFODIL COMMITTEE.

Mr. F. Herbert Chapman, Rye, presented a number of charming daffodils, and in South Saxon, a seedling from Poeticus ornatus, he staged the first of his own seedlings he has been able to set up in quantity. Torch, Chough, Blackwell, Virgil, Sonata, White Glare, Weardale Perfection, White Queen, and Duke of Bedford were varieties very well shown.

Mr. Alex. M. Wilson, Shovell, Bridgwater, exhibited a magnificent lot of new seedling daffodils all of great beauty and distinction. There were a few named sorts, notably Diogenes, Bernardino, Crœsus with vivid flat orange cup; Lola, a cream white Ajax; Conqueror, a fine trumpet variety; Cœur de Lion, Buttercup, Cornopean, and Mrs. Franklin. Some of the new unnamed varieties of what is known as the Englehearti group were of extraordinary brilliance.

A very pretty exhibit of daffodils from Messrs. Barr and Sons, Covent Garden, was greatly admired, both for the quality of its flowers and the way these were set up. Such varieties as King Alfred, Seagull, Homespun, Sunrise, White Lady, Cœur de Lion, Great Warley, Duke of Bedford, Ariadne, Plenipo, Bernardino, Bedouin, Buttercup, and Lord Kitchener were well shown.

Set up in their usual pleasing style, with isolepis between the vases, Messrs. Cartwright and Goodwin, Kidderminster, contributed a very interesting set of daffodils, their flowers clean and bright. Very striking were the blooms of Much the Miller, Golden Apple, Red Sundew, Ailsa, Barcarolle, The Skipper, Bennett Pöe, Lord Kitchener, Lemon Star, Homespun, Golden Casquet—a fine golden trumpet variety, Neptune, Circlet, and Southern Star.

Miss F. W. Currey, Lismore, Ireland, had a large and pleasing exhibit of daffodils, and staged these in larger bunches than most of the exhibitors. These bright Irish flowers included King Alfred, Scarletta, Van Waveren's Giant, White Queen, Lady of the Snows, Seagull, Michael, Duke of Bedford, Atalanta, the magnificent Crœsus, the refined pure white Mrs. Robert Sydenham, Avalanche, White Slave, and Firebrand.

From Robert Sydenham, Ltd., Tenby Street, Birmingham, came a neat group of bright flowers, and the pick of the varieties were Argent, Sir Francis Drake, Apricot Queen, Golden Gem, White Lady, Incognita, Mrs. H. J. Veitch, Homespun, Red Flag, Queen of Scots, Firebrand, the bold golden trumpet variety named King's Norton, and Orange Gem, with a large flat vivid orange cup.

Messrs. R. H. Bath, Ltd., Wisbech, showed daffodils and tulips growing in bowls of fibre; the tulips were grand, especially such varieties as Clara Butt, Bartagon, and White Swan; Madame de Graaff daffodil, in fibre, was also splendid. There were also good flowers of La Grandeur, Prince of Austria, Van Goozen, Isis, and Vermilion Brilliant tulips, and a few lovely plants of double white and double lilac primroses.

An exhibit from the Lissadell Bulb Farm, Sligo, contained branches of very fine flowers of Incognita, Lady Mary Boscawen, Ariadne, Homer, Waterwitch, King Alfred, Mrs. Robert Sydenham, Judge Bird, Mrs. J. A. Cooper, C. J. Backhouse, and Golden Bell; the flowers were large, and very clean and bright after so long a journey.

In a setting of blue primroses and golden polyanthuses Mr. W. A. Watts, St. Asaph, showed a number of seedling daffodils, very few of which were named.

VEGETABLE COMMITTEE.

Messrs. Sutton and Sons, Reading, had a fine exhibit of vegetables and salads, arranged most tastefully in baskets and boxes. The cabbages included beautiful heads of Sutton's April, Harbinger, and Flower of Spring, the latter being in good form; Broccoli Snow White was excellent, without protection. The peas included Empress of India and Early Giant, both in fine condition; seakale, rhubarb, mushrooms, and a large variety of salads were in excellent condition. The cucumbers Sutton's Market were pictures for early April; in fact, the whole exhibit demonstrated what can be done by proper selection of varieties and cultural skill.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Nephrolepis Marshalli compacta, from Messrs. H. B. May and Sons, Edmonton; to Oncoba spinosa Routledgei, from Charles E. Shea, Esq., Foots Cray, Kent; to Miltonia Bleuana var. Peetersiæ, from Firmin Lambeau, Esq., Brussels; and to Odontoglossum Ossulstoni The Shrubbery var., from Messrs. Charlesworth and Co., Haywards Heath.

Award of Merit.—To Odontioda Rosefieldiensis, from De Barri Crawshay, Esq., Rosefield, Sevenoaks; to Auriculas Mrs. Gardiner and Mrs. Harry Veitch, from Mr. James Douglas, Great Bookham; to Pelargonium Maxim Kevalesky, from Messrs. H. Cannell and Sons, Swanley; to H.T. Rose Marcelle, from Messrs. Paul and Sons, Cheshunt.

MEDALS.

Silver-gilt Flora.—To Mr. A. Wilson, Bridgwater, for daffodils; to Messrs. Barr and Sons, Covent Garden, for daffodils; to Miss F. W. Currey, Lismore, Ireland, for daffodils; to Messrs. W. Cutbush and Son, Highgate, for carnations, etc.; to Messrs. James Veitch and Sons, Chelsea, for shrubs and greenhouse plants.

Silver-gilt Banksian.—To Mr. H. Burnett, Guernsey, for carnations; to Mr. G. Prince, Longworth, for roses; to Messrs. Charlesworth and Co., Haywards Heath, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids.

Silver Flora.—To Messrs. Cartwright and Goodwin, Kidderminster, for daffodils; to Messrs. James Carter and Co., Raynes Park, for a garden exhibit; to Messrs. R. and G. Cuthbert, Southgate, for flowering shrubs; to Messrs. Mansell and Hatcher, Rawdon, Leeds, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to Messrs. W. B. Hartland and Sons, Cork, for orchids; to Sir Jeremiah Colman, Bart. (gardener, Mr. Collier), for orchids; to Lissadell Bulb Farm, Lissadell, for daffodils; to Messrs. Stuart Low and Co., Enfield, for carnations, acacias, etc.

Silver Banksian.—To de Barri Crawshay, Esq. (gardener, Mr. Stables), Rosefield, Sevenoaks, for orchids; to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids; to Messrs. J. and A. McBean, Cooksbridge, for orchids; to S. Larkin, Esq. (gardener, Mr. Hale), for orchids; to Mr. F. H. Chapman, Rye, for daffodils; Messrs. W. B. Hartland and Sons, Cork, for daffodils; to Robert Sydenham, Ltd., Birmingham, for daffodils; to Messrs. R. H. Bath, Ltd., Wisbech, for daffodils and tulips; to Mr. Paine, Kildare, for alpine plants; to Messrs. H. Cannell and Sons, Swanley, for pelargoniums; to Messrs. H. B. May and Sons, Edmonton, for ferns, roses, etc.; to Messrs. G. Mount and Sons, Canterbury, for roses; to Mr. M. Prichard, Christchurch, for hardy plants; to Mr. L. R. Russell, Richmond, for flowering shrubs.

Bronze Flora.—To Messrs. G. and A. Clark, Dover, for hardy plants; to Messrs. Wm. Paul and Son, Waltham Cross, for roses; to Mr. G. Reuthe, Keston, for hardy plants; to Messrs. T. S. Ware, Lim., Feltham, for hardy flowers; to Messrs. John Waterer and Sons, Bagshot, for rhododendrons.

Bronze Banksian.—To Messrs. Barr and Sons, Covent Garden, for hardy flowers; to Messrs. Blackmore and Langdon, Bath, for polyanthuses; to Mr. J. Box, Lindfield, for hardy plants; to Mr. A. Hemsley, Crawley, for hardy plants; to the Misses Hopkins, Shepperton, for hardy flowers; to Mr. Chas. Turner, Slough, for rhododendrons; and to Messrs. Heath and Co., Cheltenham, for alpines, etc.

Scottish Horticultural Association.

The April meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 4th inst. Mr. Massie, the president, occupied the chair, and there were 100 members present.

On the suggestion of the President, it was decided by the Council at the opening of the present session to try the experiment of devoting one of the evenings to the young members, who were asked to read short papers or notes on horticulture or any allied subject, and the venture was most gratifying, six papers being intimated. Five only of the entrants were able, however, to come forward. These were: Mr. Ernest Milne, Royal Botanic Garden, Edinburgh, subject, "The Forcing of the Strawberry"; Mr. Wm. Smith, Gosford Gardens, Longniddry, subject, "Fruit Culture in Pots"; Mr. James Reid, Carberry Tower Gardens, Musselburgh, subject, "The Making and Planting of a Rockery"; Mr. Malcolm Phillips, Granton Road Nursery, Edinburgh, subject, "Fern Raising and Growing"; Mr. C. B. Roy, Royal Botanic Garden, Edinburgh, subject, "The Young Gardener's Outlook."

The President offered two book prizes, to be awarded to those who acquitted themselves best in the reading and writing of the papers, and the judges—Messrs. Whytock, Todd, Hay, and Berry—will submit their decisions at the May meeting.

The President intimated that the Council had amongst themselves subscribed a sum of about £200 to start a fund for the foundation of a horticultural institution, and that the Council had commenced the revision of the constitution of the association.

The exhibits were: Fine collection of seedling hybrid amaryllis, from Messrs. Dicksons and Co., Edinburgh; Narcissus poetaz (N. poeticus x N. tazetta), from Messrs. Dobbie and Co., Edinburgh; hybrid Indian rhododendrons, from Mr. Duncan Macdonald, gardener to Mrs. Currie, Trinity Cottage, Edinburgh. Certificates of Merit were awarded to the following: A seedling amaryllis, exhibited by Messrs. Dicksons and Co., Edinburgh; rhododendron Mrs. David Callander (R. Dalhousianum (seedling form) x R. Nuttalli), and R. Mrs. James Currie (R. Dalhousianum (seedling form) x R. Falconeri), exhibited by Mr. Macdonald.

Three new members were elected.

On May 2 Mr. Robert L. Scarlett, Sweethope, Musselburgh, will read a paper entitled "Some Factors in the Production and Storage of Seeds."

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—W. S., Birmingham: We can most heartily recommend you to join this excellent society. The secretary, Mr. Wm. Collins, 9, Martindale Road, Balham, London, S.W., will gladly send you all necessary information. The meetings of the committee at which the nomination and election of members take place are held in the evening of the second Monday of each month, at the Royal Horticultural Hall, Vincent Square, Westminster.

PLANTING SWEET PEAS.—J. B., Rickmansworth: At the moment of writing the wind is blowing keenly from the north-east, and snowflakes fall every now and then; but probably (and we fervently hope) the weather will have improved before these lines appear in print. Do not plant out for a week or so, unless the weather improves; meanwhile, if the pots are very full of roots, give a little quite weak liquid cow manure every second watering until planting can be done. Stake the rows directly planting is finished, and, if possible, arrange some mats, evergreen boughs, fish netting, canvas, or other protecting material on the north and north-east sides of the sweet pea plot, to break up the cold winds, and thus assist the plants to make new roots. But do not place these means of protection so close to the rows that they will seriously reduce the light and make the plants draw up weakly.

HOEING.—W. R. S., Bromley: We regard the Dutch hoe as an implement of the greatest importance in the garden. In every garden of any size there should be Dutch hoes of several sizes, and these should be kept bright and clean by frequent use. Begin to hoe at once, in the kitchen garden, the herbaceous border, the fruit quarters, and the flower beds; surface cultivation and soil aeration are of the utmost importance, and their value can scarcely be over-estimated. The great mistake, as we have so often pointed out, is that of regarding the Dutch hoe merely as a tool for the eradication of weeds. The hoe should be used so regularly that weeds have no opportunity of living.

PRUNING ROSES.—J. E. G., Worksop: Reve d'Or against the south wall requires comparatively little pruning, beyond the removal of any old exhausted growths to make room for the newer vigorous ones. Fellenberg needs to be thinned out freely, removing small, misplaced, and unnecessary growths entirely; the remaining growths should be shortened a little. Gloire de Dijon should have exhausted growths removed, and the others thinned a little if necessary; hard pruning will defeat the end in view, therefore leave last year's shoots their full length provided they are uninjured; in any case, the only pruning they need is the removal of the unripened or frost-injured tips. Mdme. Abel Chatenay, if for garden purposes, should be pruned back to six or eight buds after the removal of old and superfluous growths; for exhibition purposes, prune back to four or five eyes.

MILDEW ON RADISHES.—D. S. B., Bangor: The radishes have been kept too close and damp as a general rule, and probably ventilation was given when a cold wind prevailed. The radish mildew is not usually a serious disease, and its appearance is generally due to some cultural error. Spray with a solution of sulphide of potassium.

PITMASTON DUCHESS PEAR.—J. C. W., Market Drayton: You are quite right in your contention. The pear now so well known as Pitmaston Duchess was first named Pitmaston Duchesse d'Angoulême. It was raised by Mr. Williams, of Pitmaston, near Worcester, who obtained it by crossing Duchesse d'Angoulême with Glou Morceau. The late Dr. Hogg, who gave the variety its popular name, wrote, "Bearing no resemblance whatever to the former, it might with as much reason have been called Pitmaston Glou Morceau; and, as neither name would be a misapplication, I have called it simply Pitmaston Duchess, it being sufficiently meritorious to stand on its own merits, without borrowing its reputation from any other fruit." We must all feel obliged to the worthy doctor for shortening the title.

CALIFORNIAN ANNUALS.—G. T. N., Ormskirk: So far as we can gather from your friend's description, the seeds must represent the genus Layia. Several species are fairly attractive half-hardy annuals, notably L. calliglossa, yellow; L. elegans, golden and white; L. glandulosa, white, yellow centred; and L. platyglossa, deep yellow. The layias belong to the order Compositæ; the two first named are from a foot to eighteen inches high; the third is rather taller; and the last rarely exceeds a foot in height. Treat as half-hardy annuals, and plant out in the open at the end of May or early in June.

PRUNUS TRILOBA IN POTS.—C. S. P., Chichester: As soon as the plants have lost their flowers prune the growths that have flowered back to two or three eyes from their base; then put the plants in a warm greenhouse or intermediate house, and induce them to grow freely. When the new growths have advanced a little, give weak liquid manure, increasing the strength as the shoots extend, and also the amount of ventilation at the same time. During the summer and autumn stand the plants in a sunny position so that the growths may ripen up and set flower buds. Repotting should be done, if necessary, as soon as the leaves fall, in the early autumn.

METROPOLITAN PUBLIC GARDENS ASSOCIATION.—L. G., Muswell Hill: The secretary of the above association is Mr. Basil Holmes, and his address is 83, Lancaster Gate, W. You will find a very complete list of horticultural societies, with name and address of secretary in each case, in addition to an immense amount of other information of value to those engaged in horticultural persuits, in "The Gardening Year Book for 1911"; 1s. 2d., post free, from the Gardeners' Magazine Office, 148 and 149, Aldersgate Street, E.C.

DYED NARCISSUS.—G. R., Pudsey: The flowers are cut directly they have expanded and the stems are at once placed in an aniline dye (Judson's dyes answer the purpose). The colour is taken up through the stem and soon appears in the flower. White flowers are the best for this process. Some colours are taken up more readily than others, but green, red, pink, and deep yellow are usually effective.

DISEASED PEACH TREE.—H. M., Huddersfield: We find no trace of insect infestation on the small piece of growth sent, but the colour of the leaflets at once suggests that the tree is suffering from a bad attack of the silver leaf disease. This is a fungus pest concerning which very little is at present known, and no cure has as yet been found for it. Sometimes only a portion of a tree suffers, but in other cases the trees gradually grow weaker and soon succumb. Remove the affected parts, and if the tree shows no signs of improving, take it out and burn it, re-

SWEET PEAS

Reach the greatest perfection when grown with Canary Guano. This Fertilizer increases the size and brilliance of the blossoms and doubles their number. The Fertilizer may be applied at time of sowing and as a top dressing during the early part of growth. Try it. Canary Guano is used all over the world and is sold by practically all Seedsmen.

In Tins, **6d., 1/–,** and **2/6,** and in bags from **3/6** to **20/–** each.

THE HARDY PATENT PICK CO., LTD., SHEFFIELD, ENGLAND.

make the border, and plant a good tree as early in the autumn as possible. If the latter can be obtained from the wall outside, in the same garden, and is a comparatively young tree, no crop will be lost.

BIENNIALS.—J. H., Lyndhurst: For your purpose you cannot do better than choose foxgloves, Canterbury bells, Campanula pyramidalis, Brompton, Intermediate, and East Lothian stocks (want cold frame protection in winter), Œnothera biennis, most of the verbascums, and sweet williams.

NAMES OF PLANTS.

T. L., Surrey.—1, Bifrenaria Harrisonæ; 2, probably Eupatorium Haageanum; 3, Platyclinis glumacea.

H. J., Coventry.—The anemones sent are representative of a well selected St. Brigid strain.

C. B., Stone.—1, Eupatorium Haageana; 2, E. riparium; 3, Daphne Mezereum; 4, Dracæna congesta; 5, Cycas circinalis; 6, Phormium tenax.

NEW BOOKS.

SALADS AND THEIR CULTIVATION.

By T. W. Sanders, F.L.S. (W. H. and L. Collingridge, 148 and 149, Aldersgate Street, E.C.). Price 1s. net; post free 1s. 2d.

It may be difficult to determine the season at which the liberal use of salads are likely to prove most beneficial to health, if there be any difference, but there can hardly be two opinions as to the constituents of the salad bowl being more highly appreciated in the opening months of the year than at any other period. Hence the appearance of the book now before us is most opportune. It reminds us of the supplies of tender lettuces, the delicately flavoured dandelion, the pungent mustard and cress, and the crisp radishes that are now being drawn from pits and frames, where the glass culture of salads is carried out on systematic lines, and it shows very clearly how large are the supplies that may be obtained from warm, sheltered borders and open quarters at no distant date, provided the needful preparations are made. The publication of the book is not only opportune at the present time, for its usefulness in reminding us of the supplies that may be had now and a little later on, but it makes its appearance when active preparations should be made for the provision of salads during the summer, and, indeed, for a later period. In other words, the author has placed at the disposal of his readers full information on the production of salads throughout the year at exactly the time it is likely to prove the most useful. All classes of salads are, as a matter of course, included in the book, and with the aid of the advice given there should be no difficulty in maintaining supplies of high quality throughout the year.

The usefulness and interest of the book is materially enhanced by the author giving, in addition to ample information on the selection and cultivation of the various plants used in salads, advice on the preparation of salads, and of dressings suitable, the latter being so varied as to render it an easy matter to prepare dressings suited to the most divergent tastes.

PRACTICAL SCHOOL GARDENING.

By Percy Elford, M.A., F.C.C., and Samuel Heaton, F.R.H.S. (Henry Frowde, The Clarendon Press, Oxford, and London.) Price, 2s. net.

The authors of this work are the secretary and horticultural instructor respectively to the Oxfordshire Education Committe; and in the manual before us they afford conclusive proofs as to their thorough acquaintance with gardening, and the best methods of instructing the young in the multitarious details of the gentle art. The manual should prove of immense value to those who are engaged in teaching horticulture in schools; and the young gardener who is filled with a desire to attain a high position in his profession will also find it of much assistance.

FORTHCOMING ENGAGEMENTS.

WEDNESDAY, April 19.—Royal Horticultural Society of Ireland; Spring Show.

Devon Spring Flower Show, at Plymouth; two days.

THURSDAY, April 20.—Ipswich Spring Show.

TUESDAY, April 25.—Royal Horticultural Society: Daffodil Committee meets at 11.30; Fruit, Floral, and Orchid Committees at 12 o'clock; lecture at 3 p.m. on "The Tulip—Its Problems and History," by Rev. J. Jacob; Scientific Committee at 4 o'clock.

National Auricula and Primula Society's Show, in conjunction with Royal Horticultural Society.

National Rose Society; Special General Meeting, 3 p.m. Rose Conference with address by Rev. J. H. Pemberton, 5 p.m., Dinner 7 p.m., at Westminster Palace Hotel, Victoria Street, S.W.

Kalanchoe Dyeri.—As exhibited at the meeting of the Royal Horticultural Society on February 28 last, this kalanchoe, as a decorative plant, shows greater promise than it has hitherto done. The individual plants composing a group put up by Messrs. J. Veitch and Sons were about a couple of feet high, the stout erect stems being clothed with broadly ovate leaves of a succulent character, and terminated by large heads of white flowers somewhat suggestive of an enlarged jasmine. In size they greatly surpass any of the other kalanchoes, while another distinctive feature of K. Dyeri is the fact that it blooms early in the year, whereas most of the others flower in the summer.—W. T.

Cucumbers.—These simply revel in sunny weather, and should have copious supplies of water at the root, and also overhead. Damp down the house at nightfall with soot water or liquid manure. Give top-dressings as early and as often as necessary; when the roots are observed coming through the last dressing that is the time more soil should be given. We planted out a batch of Everyday on February 14, and cut beautiful fruits on March 22. I had other varieties, but none came into use so quickly as Everyday. Sow seeds now for frames and for further supplies. Good fruits can be grown in vegetable frames, after other produce has been used; in fact, when hotbeds are used for forcing asparagus and carrots they make very suitable places for both melons and cucumbers, with but little more attention, and melons grown in this way come in very useful.—W. A. Cook, Leonardslee Gardens.

BOULTON & PAUL, LTD., NORWICH.

Protect your plants NOW—when digging—and ensure DEATH TO WIREWORMS.

If you dig in Vaporite NOW—when preparing your ground—at the rate of 1 lb. to 3 square yards, you will bring this about. Leatherjackets, Wireworms, and other soil pests must be dealt with before planting if you wish for the best results. The small quantity required makes the cost negligible compared with the improvement in the development of your plants and vegetables. The Illustrated Booklet No. 45 sent post free by the Company.

WIREWORMS.
"My gardener is delighted with Vaporite; it kills insects very quickly. The land here is very light, and infested with wireworm."—Mrs. E. A. G., Notts.

CARROTS, ONIONS, etc.
"I find after using Vaporite in the garden I had a much better lot of Carrots, also Onions, and the Potatoes were much better."—T. C., Staffs.

MODERN GLASSHOUSES

as supplied by MESSENGER and CO., Ltd., are made of the best materials, and only capable and reliable workmen are employed in the erection thereof.

The following letter was recently received by us on the completion of a contract for a well-known Member of Parliament.

February, 1911.

"I should not be doing my duty to your workmen if I did not at once tell you, on the completion of your work, how pleased I have been with each and all of them.

"They have been most obliging throughout the whole job, and have endeavoured to do everything in an efficient and thoroughly workmanlike manner, and I must congratulate you upon having such capable employees."

"CARRUSTICIDE."

The Best and Cheapest Remedy for Carnation Rust and other Fungoid Diseases.

A well-known Carnation Grower writes:

Dear Sir, The Nurseries, March, Cambs.

"During the 27 years I have been growing Carnations (Perpetual and American) I have tried most of the fungicides placed on the market, but yours is the best. It is a pleasure to see how "Carrusticide" catches hold of the Rust and destroys it. I should say your preparation will be extensively used when it is better known." Yours very truly,

GEO. CLARKE.

KELWAY'S LATEST SUCCESS.

GRAND PRIX AND GOLD MEDAL, Japan-British Exhibition, White City. Unanimous award of the International Jury to Kelway and Son for Pæonies, Delphiniums, Gladioli, Pyrethrums, etc.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

THE KELWAY ARTISTIC BORDER ensures a garden of enduring beauty from early Spring to late Autumn with a minimum of cultivation, and without the trouble of constant digging or bedding-out. The plants composing the border are selected by experts, and include some of Kelway's improvements in Pæonies, Delphiniums, etc. Send dimensions of spaces to be filled, or for Kelway's "Gardens of Delight," 6d. The cost of this border is 15s. or 25s. for every 10 square yards. Carriage and package free for remittance with order.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

KELWAY'S MANUAL OF HORTICULTURE is the best of all Garden Books. 2s. post free, from KELWAY and SON, LANGPORT, SOMERSET.

NOW IS THE TIME TO PLANT KELWAY DELPHINIUMS, which have been improved almost out of recognition in the past twenty years. They produce plants ranging in height from four to eight feet, exceptionally hardy and with a rich profusion of choice blooms in all the shades of that valuable colour, blue.

Choice named varieties: 24s., 34s., and 56s. a dozen. Carriage and package free for remittance with order.

The celebrated present-day Delphiniums, and nearly all the best well-known varieties shown at exhibitions, originated in Kelway's Langport Nurseries.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

IRON and WIRE FENCING for GARDENS, Tree Guards, Gates, Arches, Espaliers, Rose Stakes, and Ornamental Garden Iron and Wire Work of every description. Send for Illustrated Catalogue, free. BOULTON and PAUL, Ltd., Manufacturers, Norwich.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Variable Weather.

From a superficial point of view the great variability of the weather experienced in most parts of the world is a profound puzzle, independently of the seasonal influences which are readily understood, depending as they do on the gradual waxing and waning of the sunshine, due to the revolution of the earth around the sun on an oblique axis. This, of course, determines the gradual approach and retreat of the North and South Poles alternately to and from the solar influence, which naturally increases and reduces the amount of vital illumination received on the earth's surface, and thus determines warmer and colder seasons. All this, however, runs as smoothly and as regularly as clockwork; year after year and æon after æon, the earth rolls and has rolled smoothly around the sun, returning every year to the same point, and then commencing a new revolution. There is nothing here apparently to hinder an equally even change of seasons, merely diversified by an equally regular increase and decrease of warmth and illumination, yet practically no two years are alike. Sometimes, as this year, the cold blasts of winter invade the spring, and at others, bright warm sunshine intervenes to mitigate the winter, while it is within the memory of many that years have been experienced in this so-called temperate climate when the rigour of winter has even extended well into the summer season proper, keen frost and heavy snowfalls occurring up to the end of May or even into June. If now we seek the cause of such great vacillations in cataclysmic changes of conditions on the earth's surface sufficient to account for such an upsetting of normal conditions, volcanic eruptions or anything of that sort, we seek in vain. Even our meteorologists with all their knowledge are utterly unable to predict the coming conditions long beforehand, and are quite dependent for the predictions they do make on ascertained existing factors near and far which denote the approach or retreat of aerial disturbances for which they are unable to account in the slightest degree. One thing only is certain, and that is that the great and often sudden changes are due to aerial disturbance, which leads to changes of temperature which in their turn determine the formation of rain, snow, or hail, as the case may be, accompanied by more or less violent aerial currents due to the inequality of pressure which these disturbances involve. One great factor in variation is undoubtedly the diversity of the earth's surface itself, broken up as it is on land into mountain ranges, and on the broad ocean surfaces by islands and continents, all of which exercise their effect on the great system of circulation both of air and water, which forms the basis of weather conditions. These, too, however, it may be justly argued, are, as a rule, regular factors like the earth's revolution itself and the consequent seasonal results, and thus afford no clear clue to the variability we treat of. In short, we are driven to look farther afield for the main disturbing factor, and in all probability we may seek this in the great solar orb itself. This, as the astronomer will tell us, has not, like the earth, cooled down into solid and more or less stable conditions, but is undoubtedly the scene of inconceivably vast convulsions and eruptions of molten and gaseous matter, which, like the light and heat with which we are familiar, make these influences felt upon the planets, the earth, of course, included. Electric influences, too, undoubtedly figure largely in this connection. Here, then, we have a constantly fluctuating factor, and, considering its potency, it is not unreasonable nor illogical to impute to this cause much of the otherwise incomprehensible changes which affect our atmosphere, breeding gales and hurricanes, and thus sweeping at one time the cold air of the polar circle into warm southern regions, and at another reversing the process, in this way at once accounting fully for the apparent waywardness of the elements. Once, in short, set winds so engendered in motion, and immediately there disappear all theories regarding cosmic regularity of season, since all equilibrium is upset by the resulting conflict. That the cause we have suggested is probably the main one is already evidenced by certain agreements between sun spots, i.e., indications of solar storms, coinciding with abnormal weather conditions on earth, and, considering this, it is clear that, so far from its being a wonder that weather is fickle, it is rather a marvel that we should ever have periods of stable fine weather at all.

MR. R. S. HALLEY.

Mr. R. S. Halley, whose portrait is given in this issue, belongs to the ever-increasing band of sweet pea enthusiasts, and in the work he has accomplished on behalf of the flower in which he is so greatly interested, he has done excellent service in the cause of floriculture across the Border. We need hardly say that for many years past sweet peas have been successfully grown in Scotland by Mr. Malcolm and other cultivators, or that these fragrant flowers have annually constituted a delightful feature of the autumn exhibitions held by the Royal Caledonian Horticultural Society, for these facts have all been duly recorded in our pages by Mr. Halley. But until some eighteen months ago the Scottish enthusiasts had no common meeting ground north of the Tweed; or, to state the case in another way, they had no society wholly devoted to their favourite flower. To Mr. Halley belongs the credit of recognising the desirability of a sweet pea society being established in Scotland, and to his initiative the founding of the Perthshire Sweet Pea Society is due. As Mr. Halley tells us in our sweet pea number (January 21, 1911), he is in the habit of attending many of the flower shows in Scotland, and. believing the time ripe for the formation of a society to bind the growers together, he brought the matter before other enthusiasts. The project was received with much favour, a strong society was formed, and in July last an exhibition held that was remarkable alike for its extent and the high development of the flowers in competition. Although this new organisation is designated the Perthshire Sweet Pea Society, and has its headquarters at Perth, it embraces within the scope of its operations the whole of Scotland. As the first Scottish society it was necessarily the most northern organisation wholly devoted to sweet peas, but this is no longer the case, for its influence has been so great in the far North that a society has been formed at Strathpeffer. Mr. Halley may be heartily congratulated in what he has accomplished, and we trust the Scottish sweet pea enthusiasts may long have him for their leader.

Hollies, Rhododendrons, etc.—In view of the favourable opportunity that is now presented for the planting of hollies, rhododendrons, ivies, and some other evergreens, we shall include in our next issue (April 29) special articles on hollies, rhododendrons, ivies, and evergreen shrubs with variegated leafage. As the ornamental vines may now be successfully planted from pots, there will be a special article on them. The issue will be freely illustrated, the illustrations being chiefly associated with the special articles.

The Easter Holidays proved a thoroughly enjoyable time for all who could get out of doors to enjoy the brilliant sunshine and the south-westerly breezes. The weather was bright and warm without being really hot. There was a tremendous exit from London and other big cities and towns, the country and its beauties attracting immense crowds, while to the enthusiastic gardener the time was all too short. The Continental and other long-distance traffic from London was unusually heavy. In and around London the holiday crowds were great on Easter Monday. On Hampstead Heath no fewer than 300,000 people disported themselves; 43,407 went to the Zoological Gardens, and over 144,000 had a good time among the daffodils and other spring flowers at the Royal Gardens, Kew. Hampton Court Palace was visited by 16,854 persons, but there were thousands who wandered round the gardens and over the green and did not enter Wolsey's palace. At the Natural History Museum, the Science Museum, the Victoria and Albert Museum, and the National Gallery the visitors were fewer than usual owing to the attractive power of the sunshine outside. The River Thames was thronged from Kew to Windsor, and the Crystal Palace attracted its many thousands. Throughout the Southern counties the maximum shade temperature on Easter Monday ranged from 50 degrees to 62 degrees, and the bright sunshine record ranged from three to eight hours, Hastings apparently enjoying the most sunshine. A falling barometer and southerly or south-westerly breezes suggested the approach of rain, and now that the holidays are over some warm April showers would do no harm but would be welcomed because of the good they would do in garden and farm.

Royal International Horticultural Exhibition, 1912.—The directors of the Royal International Horticultural Exhibition, 1912, ask us to intimate to our readers that, in view of the numerous applications for space at the exhibition, it is necessary for the sub-committee dealing with the matter to obtain some idea of the proportion which the total demand will bear to the area at their disposal. They will, therefore, be much obliged if exhibitors will intimate at the earliest date possible the nature of any exhibit, whether competitive or otherwise, which they propose to submit, together with a note of the area in square feet which it is likely to occupy. The Spacing Committee will, of course, do their best to satisfy the demands of intending exhibitors, but it will be understood that this request for information does not necessarily imply that the committee will be in a position to grant all the space that may be asked for. Under any circumstances, the work of allotment must be a difficult matter, and the committee rely upon the kind assistance of exhibitors in the simplification of their task.

Heath and Forest Fires.—Within the past ten days an immense amount of damage by fire has been done on heaths and in woodlands in various parts of the country. On the line of hills extending from Folkestone to Beachborough fires extended over large tracts of heath land and destroyed the vegetation thereon. In one case the line of fire was several thousand feet in length, and it was only by the most strenuous endeavour on the part of a large number of people that the flames did not reach the plantations around Beachborough Hall. A few days later some twenty acres of gorse on Hayes Common was destroyed by fire. Still more destructive was the forest fire which occurred in Perthshire. This fire originated in Carsie Woods, the property of Mr. William Panton, and, favoured by the dry state of both the trees and undergrowth and a strong wind, it rapidly spread to the woods of Meikleour, the Perthshire seat of the Marquis of Lansdowne. Here upwards of one hundred acres of Scots fir, almost full grown, and a plantation of young trees were destroyed. It is reported that for over a mile in length the wood resembled a fiery furnace, the flames leaping to a height of between twenty and thirty feet, and it was at one time feared that the whole of the wood, which has an area of 300 acres, would be destroyed, but happily this disaster was averted. The Meikleour estate is remarkable for the famous hedge which borders the public road, of which we gave an illustration two or three years since. It is a quarter of a mile long, is 80 feet high, and was planted in 1747.

Lord Kitchener's New Garden.—While in India Lord Kitchener acquired the reputation of being a skilful and enthusiastic gardener, and now the opportunity to display his talents in connection with the "gentle art" appears to have arrived, for we understand that his lordship has purchased Broome Hall, near Canterbury. Broome Hall stands at a considerable elevation, and is surrounded by a splendidly timbered park.

The Mosquito Plant. — Eight years since Major H. D. Larymore, who was engaged in Northern Nigeria, described in a letter to the "Times," the basil plant (Ocymum viride) and its peculiar properties in keeping away mosquitoes. His opinion was corroborated by Sir George Birdwood, who stated "when the Victoria Gardens and Albert Museum were established in Bombay the men employed on these works were at first so pestered by mosquitoes, and suffered so much from malarious fever, that on the recommendation of the Hindu manager the whole boundary of the gardens was planted with holy basil, and any other basil at hand, on which the plague of mosquitoes was at once abated, and fever altogether disappeared from among the resident gardeners." The contention that basil possessed such protective value was discredited by several authorities. In a letter, published a few days since, Major Larymore states that during the past ten years he has continued to sow the seeds of the basil wherever he has been stationed, and that "the immunity from fever which both my wife and I have experienced for the past ten years in West Africa, speaks for itself." He also directs attention to the fact that the results of a preliminary investigation at the Laboratory of the Imperial Institute by Dr. Goulding, D.Sc., and Mr. Pelly have been published in the Proceedings of the Chemical Society, and show that leaves of this plant imported from West Africa contain a volatile oil which possesses the same aromatic, thyme-like odour of the leaves in a highly concentrated degree. An analysis of this oil showed that it contained 32 per cent. of thymol, together with other aromatic substances. Now thymol is a recognised antiseptic and most powerful germicide, and in "The Extra Pharmacopœia" it is stated that "ten grains dissolved in an ounce of soft paraffin applied to the skin keeps off gnats and mosquitoes." It is easier now observes Major Larymore to understand the real reason why the plant repels mosquitoes—containing as it does in its oil so very large a proportion (one-third) of such a powerful antiseptic as thymol appears to be, and the further analysis which Dr. Goulding purposes to conduct will be looked forward to with interest.

Lister Park, Bradford.—Some of the ratepayers of Bradford are opposing a proposal of the City Council to cut down a number of trees in this park in order to widen Keighley Road. Application was made to the Local Government Board for permission to carry out the project, but the Board replied to the effect that they had no power to give permission for the appropriation of a portion of the park for such purpose. The City Council have taken the view that, if the Board have no power to sanction the proposed alteration, they could not prevent it being made, and decided to proceed with cutting down the trees. This decision has given rise to considerable feeling, and the ratepayers who are opposed to the cutting down of the trees are talking of applying to the High Court for an interim injunction and to contest the legality thereof.

Damage from Overhanging Trees.—An interesting case was heard at the Lambeth County Court on the 7th inst., having reference to damage caused by trees alleged to project over the roadway. Mr. Charles William Carpenter, a cartage contractor, of Queen Street, Hammersmith, claimed £11 3s. 9d. from the Camberwell Borough Council, being damage done to furniture and a pantechnicon caused through the alleged negligence of the defendants, or their servants, by allowing trees to overlap the roadway. While the pantechnicon was being driven down Camberwell New Road the trees swept certain furniture and other articles off the vehicle. Mr. Leon Freedman, counsel for the plaintiff, said that the trees were vested in the local authority, but Mr. Cecil Whiteley, for the defendants, said he should require proof of that. The plaintiff stated that at a height of 9ft. the tree trunk projected several inches over the roadway. He produced a photograph. The Judge remarked that it appeared from the photograph that the tree was older than the Act counsel was dealing with. Mr. Freedman asked if he damaged the tree, who would fine him? and Judge Parry, in reply, said he did not say that anybody would; but he might try cutting it down and see what would happen. In the result the plaintiff was nonsuited, with costs.

Conversazione of the Selborne Society.—The annual conversazione of this society will be held on May 5 in the theatre and halls of the Civil Service Commission, Burlington Gardens, W. There will be exhibits of rural industries including the prehistoric occupation of flint knapping, which still survives in Suffolk, etc. The Keeper of the Brent Valley Bird Sanctuary will be at work making boxes, and an unpublished MS. of Gilbert White will be on view. The president, Lord Avebury will take the chair in the theatre, and an illustrated lecture on "The Eggs of Butterflies and Moths" will be given by Mr. F. Noad Clark. Tickets can only be obtained through members of the society.

Experimental Culture in Staffordshire.—The field experiments carried out under the auspices of the Education Committee of the Staffordshire County Council and at the Harper-Adams College, Newport, Salop, in 1910 were varied in character and of importance both to gardeners and farmers. The annual report has just reached us, and from this we learn that the manurial experiments of the Education Committee were carried out with the aid of potatoes, sugar beet, mangels, swedes, and meadow land. Somewhat similar experiments were conducted on the college farm, and, in addition to other work of a varied character, the wart disease of potatoes was fully investigated and much valuable information relating thereto obtained. The results are embodied in the report, and are fully deserving of the careful attention of all who are interested in potatoes.

Fruits from Barbados.—A promising beginning has been made in the export of fruits from Barbados to England. Bananas, Avocado pears, and mangos have been sent, but there is need for more experiment with the two latter crops ere they can be sent on a long journey successfully. Sweet potatoes and yams have also been sent and have arrived in good condition.

The Botanical Magazine for the current month contains a double-page illustration of Clematis aristata Dennisæ, a free, white-flowered Australian variety with salmon-coloured filaments; Pseuderanthemum malaccense, a Malayan acanthad with clusters of long-tubed, pale violet coloured flowers; Eleagnus argentea, a hardy shrub from North America, with metallic grey leaves and axillary clusters of small yellow flowers; Felicia petiolata, a South African composite of lowly growth, with rosy florets to the daisy-like flowers; and Dendrobium muricatum munificum, a short-bulbed orchid from New Caledonia, and one that bears a many flowered raceme of green, brown spotted blooms.

Judging Sweet Peas.—At the Sweet Pea Conference held under the auspices of the National Sweet Pea Society last December, Mr. W. P. Wright proposed the following scale of points for judging sweet peas: Freshness and good colour, 6 points; number of flowers per stem (three to four), 4; length of stem (approximating 18in.), 4; arrangement of flowers on stem, 4; size of bloom, approximate width of standard (¾in.), 4; colour blending, 2; total, 24. The National Sweet Pea Society of America has decided that its scale of points for judging shall be: Stem, 25; colour, 20; size, 25; number of flowers per stem, 15; substance, 15; total, 100 points. As already indicated in these pages, a simplified method of pointing was arrived at by those present at the N.S.P.S. Conference, following on the lines frequently adopted by chrysanthemum judges. It is as follows: "Give a maximum of 6 points per bunch. This maximum to be allocated to the best bunch, or bunches, in the stands, and then point the other bunches, by half points if necessary, working downwards from the maximum. In awarding these points due regard must be given to freshness, quality, and size of flowers. It is also recommended, where necessary (i.e., when the bunch pointing brings an equality, or nearly so), that 6 points extra be taken as a maximum for arrangement and blending of colours, the points so obtained being added to the total bunch points. Double-standard flowers should not be discounted."

The Japanese Gate at Kew.—Our readers were informed last autumn that the facsimile of the Kyoto Gate, which was exhibited at the Japan-British Exhibition at Shepherd's Bush, had been presented by the Japanese Government to the Royal Gardens, Kew. Reference to this gate is made in the "Journal of the Kew Guild" as follows: "A new feature, erected under Japanese supervision, will be found beneath the old Cedars on Mossy Mound, between the Holly Walk and the Pagoda. This is a facsimile of an old sacred gateway at Kyoto, the capital of Old Japan. It was exhibited at the recent Japan-British Exhibition, and was presented to the Royal Gardens, Kew, at its close. The Exhibition Guide gives a description of the original gateway: from it the following notes are extracted: The gate called Chokoshi Mon, or Royal Gate, is a representation of the sacred gateway to one of the temples in Kyoto. Through the doorway only the Emperor, the members of his family, or his representatives are allowed to pass. The original is to be seen in the Temple of Higashi Hong-wanji, the largest Buddhist temple in Japan, and one of the most magnificent. It is rightly called the St. Peter's of Japan, having been erected by the people at a cost of £1,600,000. Seventeen years were occupied in its building. The gate in question is made of the wood of Cupressus obtusa and is of an ornamental character. It was made in Japan and shipped in sections to the White City, where it was found to be so accurately made that it could be fitted together without any alterations."

Nursery Inspection in New York State.—Some idea of the importance attached to the inspection of nursery stock in America can be gathered from the eighteenth annual report of the New York State Department of Agriculture. This shows that during the year 572 nurseries were inspected, and all stock examined, including 116,640,977 trees and plants of different kinds. Seventeen thousand and eighty-one trees were destroyed on account of being infested with San José scale, which, if distributed to parts of the State now free from this pest, would have caused untold damage. More than twelve million seedlings recently imported were examined, and 3,726 nests of brown-tail moths, as well as some nests of gipsy moths, found, and destroyed. Thus far, although they have appeared at more than a score of different places in the State, agents of the department have in every instance completely eradicated these insects. The importance of this work may be estimated when it is stated that in Massachusetts last year more than $1,000,000 was spent by Federal, State, and municipal governments for the purpose of keeping under control these pests, which, unfortunately, have gained a foothold there.

FERN SPORE PODS.

When we compare ferns with flowering plants we find them distinguished by several characters, of which the main consist in the circinate form of vernation, or frond development, which, with a few insignificant exceptions, characterises them all, and the fact that they are reproduced by spores instead of seeds.

Circination, it may be explained, implies that the fronds, in their young state, are rolled inwards, so that as they develop and the stalk lengthens a coil is seen, which gradually loosens and expands into the more or less flat frond, the secondary, or tertiary, or even further divisions, developing in the same way from laterally coiled segments, while in flowering plants, as a rule, the foliage is arranged in the bud on straight lines, involving no uncoiling process, even the coiling of tendrils, stems, etc., being a subsequent operation often induced by sensitiveness to touch with neighbouring growths or other supports.

A further character, however, exists in the nature of the pods or capsules borne by ferns as receptacles for their spores. In flowering plants the equivalent reproductive bodies, i.e., the seeds, are contained in vessels of an almost infinite diversity of size, shape, and make associated with innumerable contrivances to facilitate distribution when ripe. In ferns, however, on the other hand, despite their diversity of make of foliage, habit of growth, size, etc., the spore receptacle is, in the vast majority of cases, practically alike, and its method of scattering the spores abroad the same. This receptacle, or sporangium, consists of an oval capsule, usually of a lucent brown colour, which is attached to the frond by a ribbed stalk. These ribs continue as a ridge from the point of junction to the capsule, right over the top, and halfway down the other side, so that the capsule, to some extent, resembles a fireman's or policeman's helmet. When the spores are ripe, this ribbed ridge contracts, and eventually by such contraction exercises such a strain upon the capsule at the point where the ridge terminates, that it suddenly splits there, the opening gradually widening until the top half is turned upwards, when the sudden disruption of the few retaining cells throws it violently backward, jerking the contents in all directions. This curious process can be easily seen if a small portion of a fertile frond be scraped as soon as the brown colour of the sporangia indicates ripeness, and the capsules be allowed to fall upon the glass slip of a microscope. Viewed then in a warm room, they will appear at first as a loose heap. Presently this heap will begin to display twitching movements, indicating the first rupture of the capsules, which may be seen to be gaping wider and wider until quite suddenly the whole heap is broken up, as by an explosion, and spores will be noticed falling like a miniature hail shower upon the bare portions of the glass slip, which eventually becomes profusely peppered over with them, mingled with the now empty capsules. For sowing purposes, if the slip be now gently breathed upon until it appears misty, the spores will thereby become temporarily attached to it, and a smart puff will remove the capsules and other debris, leaving them clean and ready for sowing when the moisture evaporates.

In some species, Osmunda regalis, for instance, the capsules are plain, and the spores escape by simple lateral splitting; in other genera there is a horizontal ribbed ring round the top of the capsule, which acts similarly to the perpendicular ones by contraction on the same principle. There is also some diversity of size, colour, and make of the spores themselves. Those of the common Polypody (Polypodium vulgare) are a bright yellow, as are the capsules themselves, those of Osmunda a dull green, but in the great majority of species they only vary in grades of brown or nearly black. In shape they may be smoothly oval, oval with irregular projections, or bluntly pyramidal. The size, however, is always nearly microscopic, so that in this respect there is a vast difference between ferns and flowering plants as regards the diversity of size of the seed of the latter and the spore of the former. Nor are spores ever accompanied by any of those adjuncts of attractive pulp, etc., which are seen in fruits proper; they are, indeed, very simple bodies, consisting merely of a reproductive cell protected by a husk or shell, and only capable of producing the parental form of fern after first developing a small green structure termed the "prothallus," on the underside of which the equivalents of male and female flowers are engendered, and an embryo seed, embedded in its substance, fertilised.

It is clear that the absence of any conspicuous flowers, and the consequent non-attraction of the insect world for fertilising purposes, has been the main factor in what may be termed the evolutionary stagnation in ferns, those of the present day strongly resembling the fossil species of the Coal Age in general character. There is, however, great diversity in the ways in which the spore capsules are arranged upon the fronds, and the mode of such arrangements being the most constant factor in each genus, it has been adopted by botanists for classification purposes. Thus, if we take one genus, the Polypodiums, for instance, we shall find all the many species embraced therein to have the spores arranged in round or oval heaps, entirely without a protective cover, or "indusium." In the common Bracken, as a type of another extensive genus, we find the spores arranged in continuous marginal lines, the edge of the frond being turned back to form the cover in question. The Lastreas, or Nephrodiums, have round heaps, protected by a kidney-shaped cover attached to the centre, and the Polystichums differ by having a circular one.

In the Osmunda we see the spores all collected at the frond tips, where, the leafy portion being suppressed, a rough resemblance to a faded spiræa inflorescence is produced, whence the common but incorrect name of the "flowering fern." The Davallias have their spores in little cups inserted in the frond edges, and in the Platyceriums special fronds are produced, the backs of which are coated, as it were, with a uniform layer of capsules near their tips. Each genus, in short, has its distinctive arrangement, and these are so diverse that exigences of space entirely preclude full description. Our most familiar native species, however, may be distinguished thus, the Polypodies, Lastreas, Polystichums, Osmunda, and Bracken are already described; besides these there are the Spleenworts, with spores in straight lines, arranged herring-bone fashion; the Hart's-tongues, with much larger heaps on like lines, but in faced pairs, the cover springing from opposite sides, which coalesce when ripe. The Lady Fern (Athyrium) has them of a rough horseshoe form, with a ragged central cover. The Bladder Fern (Csytopteris) as dots, with bladder-like covers; the Hard Fern (Blechnum) on special erect attenuated fronds: the Filmy Ferns in marginal cups, something like the Davallias, but more projecting.

Chas. T. Druery, V.M.H., F.L.S.

ROCK GARDEN NOTES.

The rock garden is now looking bright, and much attention is necessary at this season to keep everything in order. A nightly inspection should be maintained to prevent slugs eating the choice flowers and new growths. Hand picking, with the aid of a lantern, is the surest way to keep them down. Should there be any length of dry weather watering must be resorted to, or plants which were put out last month will suffer greatly. The dwarf primulas will require to be closely watched, or the small birds will soon ruin the flowers. A few strands of black cotton stretched over the plants will usually frighten the marauders. The oppositifolia group of saxifragas should be top-dressed when their flowering season is over to keep them in good condition. Some fine gritty soil, with a little old mortar mixed with it, should be sprinkled over the plants, and well worked amongst the stems with a pointed stick, afterwards watering with a fine rose to settle it.

Ramondias will need abundance of water during dry weather, as the foliage soon shrivels when the plants become dry at the roots. A simple and effective plan to adopt with regard to watering is to bore a few holes with an iron bar behind the plants and fill them up with water, when the soil will be thoroughly soaked. It is useless trying to water the plants from the front, and also very harmful. Ourisia coccinea may have a slight top-dressing of peat, and a few extra stones placed amongst the young growths will prove beneficial. It is a plant that loves to spread about over stones, and every encouragement should be given to induce it to thrive.

There are numbers of tender plants most suitable for the work which may be wintered in cold frames and planted out in April or May. Mesembryanthemums create a fine effect when given a position in full sun, as also does Convolvulus mauritanicus. This latter should be given a spot where its slender shoots can hang over stones. Of Lotus peliorhynchus, Asteriscus maritimus, Antirrhinum azarina, Sphæralcea Munroanum, and Amphicome Emodi, a stock may be maintained by propagating annually by cuttings, which root quickly in close cold frames if taken early in August, and make good plants for putting out the following season. A small frame should be reserved specially for propagating all classes of rock garden plants, and should have a bed of clean sand in it, for this will be found the most suitable rooting medium. I have tried many schemes for propagating the most difficult plants, and have come to the conclusion that there is nothing better than pure sand. The one thing to guard against is dryness, for once the sand is allowed to remain dry for any length of time the cuttings are almost sure to perish. Another thing, immediately they are rooted potting must be attended to. I have practised this method of propagating with excellent results, and always obtain a splendid percentage of rooted plants.

There are various annuals which adapt themselves wonderfully well to the rock garden, and these may be either raised in boxes, and planted out, or sown where they are intended to flower. Ionopsidium acaule (Violet Cress) is a beautiful miniature plant suitable for damp crevices, and when once established, will reproduce itself freely. Portulaca should be sown in dry, sunny spots, and slightly thinned when the plants are large enough to handle. The dwarf forms of leptosiphons, such as aureus, roseus, and hybridus, are excellent for the purpose, also Limnanthes Douglasi. Phacelia campanularia has blue flowers rivalling the gentians, and is easily grown, and when seen in a mass is very effective. Nemophila, calandrinia, nycterinia, sanvitalia, Campanula attica, annual erysimums, and many others all lend themselves to rock garden effect.

Diascia barberæ requires to be treated as a half-hardy annual in cold districts, but when grown in warm nooks in the Southern counties it is perennial. Although hardy plants are generally associated with rock gardens, there is no reason whatever why suitable plants of annual habit should not be grown, for they certainly provide an additional interest, without being out of place. When the aubrietias, alyssums, helianthemums, arabis, etc., which supply the colour effect, have finished flowering the garden is inclined to look rather dull, and this is where the value of annuals begin. E. C. Pooley.

ROSES OF DISTINCTIVE COLOURING.

A small number of roses are so peculiarly coloured as to deserve a few remarks. Of recent years this has become more noticeable, and causes this brief note.

Not all of these are new, however, for one of them is the Austrian Copper, with a colour I fail to find in any other flower, much less in roses. Grand indeed is this oldest of roses, in its bright and glowing copper, shaded with clear terra-cotta. If it were only perpetual, and not so fleeting for the short time it is with us, it would be of immense value. Leading from this class of Austrian and Persian briars we find Soleil d'Or, in 1900, obtained from crossing Persian briar Harrisoni with Antoine Ducher. Here we have a colour varying from deep orange-yellow to reddish-gold, shaded with nasturtium-red, and quite distinct from any other rose. A couple of years later we had Gottfried Keller, another remarkably shaded rose, varying from clear apricot to orange and yellow, with veins of deep rosy-orange at the base of its petals. The crosses from seedlings of Soleil d'Or are giving us some of the most unique colour of all, Lyon Rose being now well known, with its coral or shrimp-pink, suffused with deep orange-yellow. Arthur R. Goodwin varies from coppery-red to salmon-pink. But one of the most unique shaded of all is Rayon d'Or, a rose there is considerable discussion about just now, because of its very indifferent behaviour up to the present. This is as yellow as the marsh marigold, with a streak of orange and red in the bud stage.

In Irish Elegance we have a single rose that is almost indescribable in its shadings of bronzy-orange and apricot. Jacques Vincent is another difficult to describe. Its main shades are coral-red and yellow, with a rosy-salmon centre; a very hardy and beautiful variety this. Juliet is a cross between Soleil d'Or and Captain Hayward, and a charming combination of the glorious shades of these grand roses has resulted. Hugo Roller must not be omitted; rich rosy-crimson on the outer petals, with a lemon-yellow centre. The aptly-named Beauté Inconstante has coppery-red, carmine, and yellow flowers, with seldom two shaded alike. Many peculiarities are found in the striped roses, such as York and Lancaster, Merrie England, Pride of Reigate, and Rainbow. In Grand Duc A. de Luxemburg and Mrs. E. G. Hill we have deep coral rosy-reds on the reverse of the petals that give the flowers a peculiar appearance.

A. P.

MESEMBRYANTHEMUM PYROPEUM.

With the exception of M. cordifolium variegatum, so extensively used for summer bedding, the mesembryanthemums are not extensively cultivated in other than the warmest and brightest parts of the country. This is due largely to the fact that certain plants are so immensely popular and useful that they crowd out others equally interesting and beautiful; a wider knowledge of plants is rapidly growing, and, as a result, these beautiful and somewhat rarely seen subjects are steadily growing in favour among those who do not wish their gardens to be mere copies of their neighbours. One of the annual mesembryanthemums is herewith figured; it is M. pyropeum, also known as M. tricolor and M. tricolorum. It is a Fig Marigold of great beauty, and in a sunny season it is remarkably effective. Sown in April on rich light soil, to which some lime rubble has been added, it soon germinates, grows readily, and in sunny weather is a blaze of flowers that are crimson, with a pink zone round the dark eye. The long acute leaves, with their numerous little glistening glandular protuberances, make the plant still more interesting. A warm sunny position is the best for this species, as indeed it is for all mesembryanthemums, as they love sunshine. Those who have been privileged to see the huge masses of various mesembryanthemums growing on the rockwork at Tresco Abbey Gardens, in the Scilly Isles, will not need to be told of their beauty on a sunny day; but whereas many of those species do not grow satisfactorily out of doors in cooler districts, M. pyropeum is one that may be depended upon in the Midlands and the Southern Counties in a bright season. It should be remembered that this annual does not take kindly to transplantation, and therefore should be sown where it is to remain and flower.

MESEMBRYANTHEMUM PYROPEUM. [Photo: C. P. Raffill.

A hardy species of annual duration, and producing a profusion of crimson flowers.

THE VALUE OF THE ROOF GARDEN.

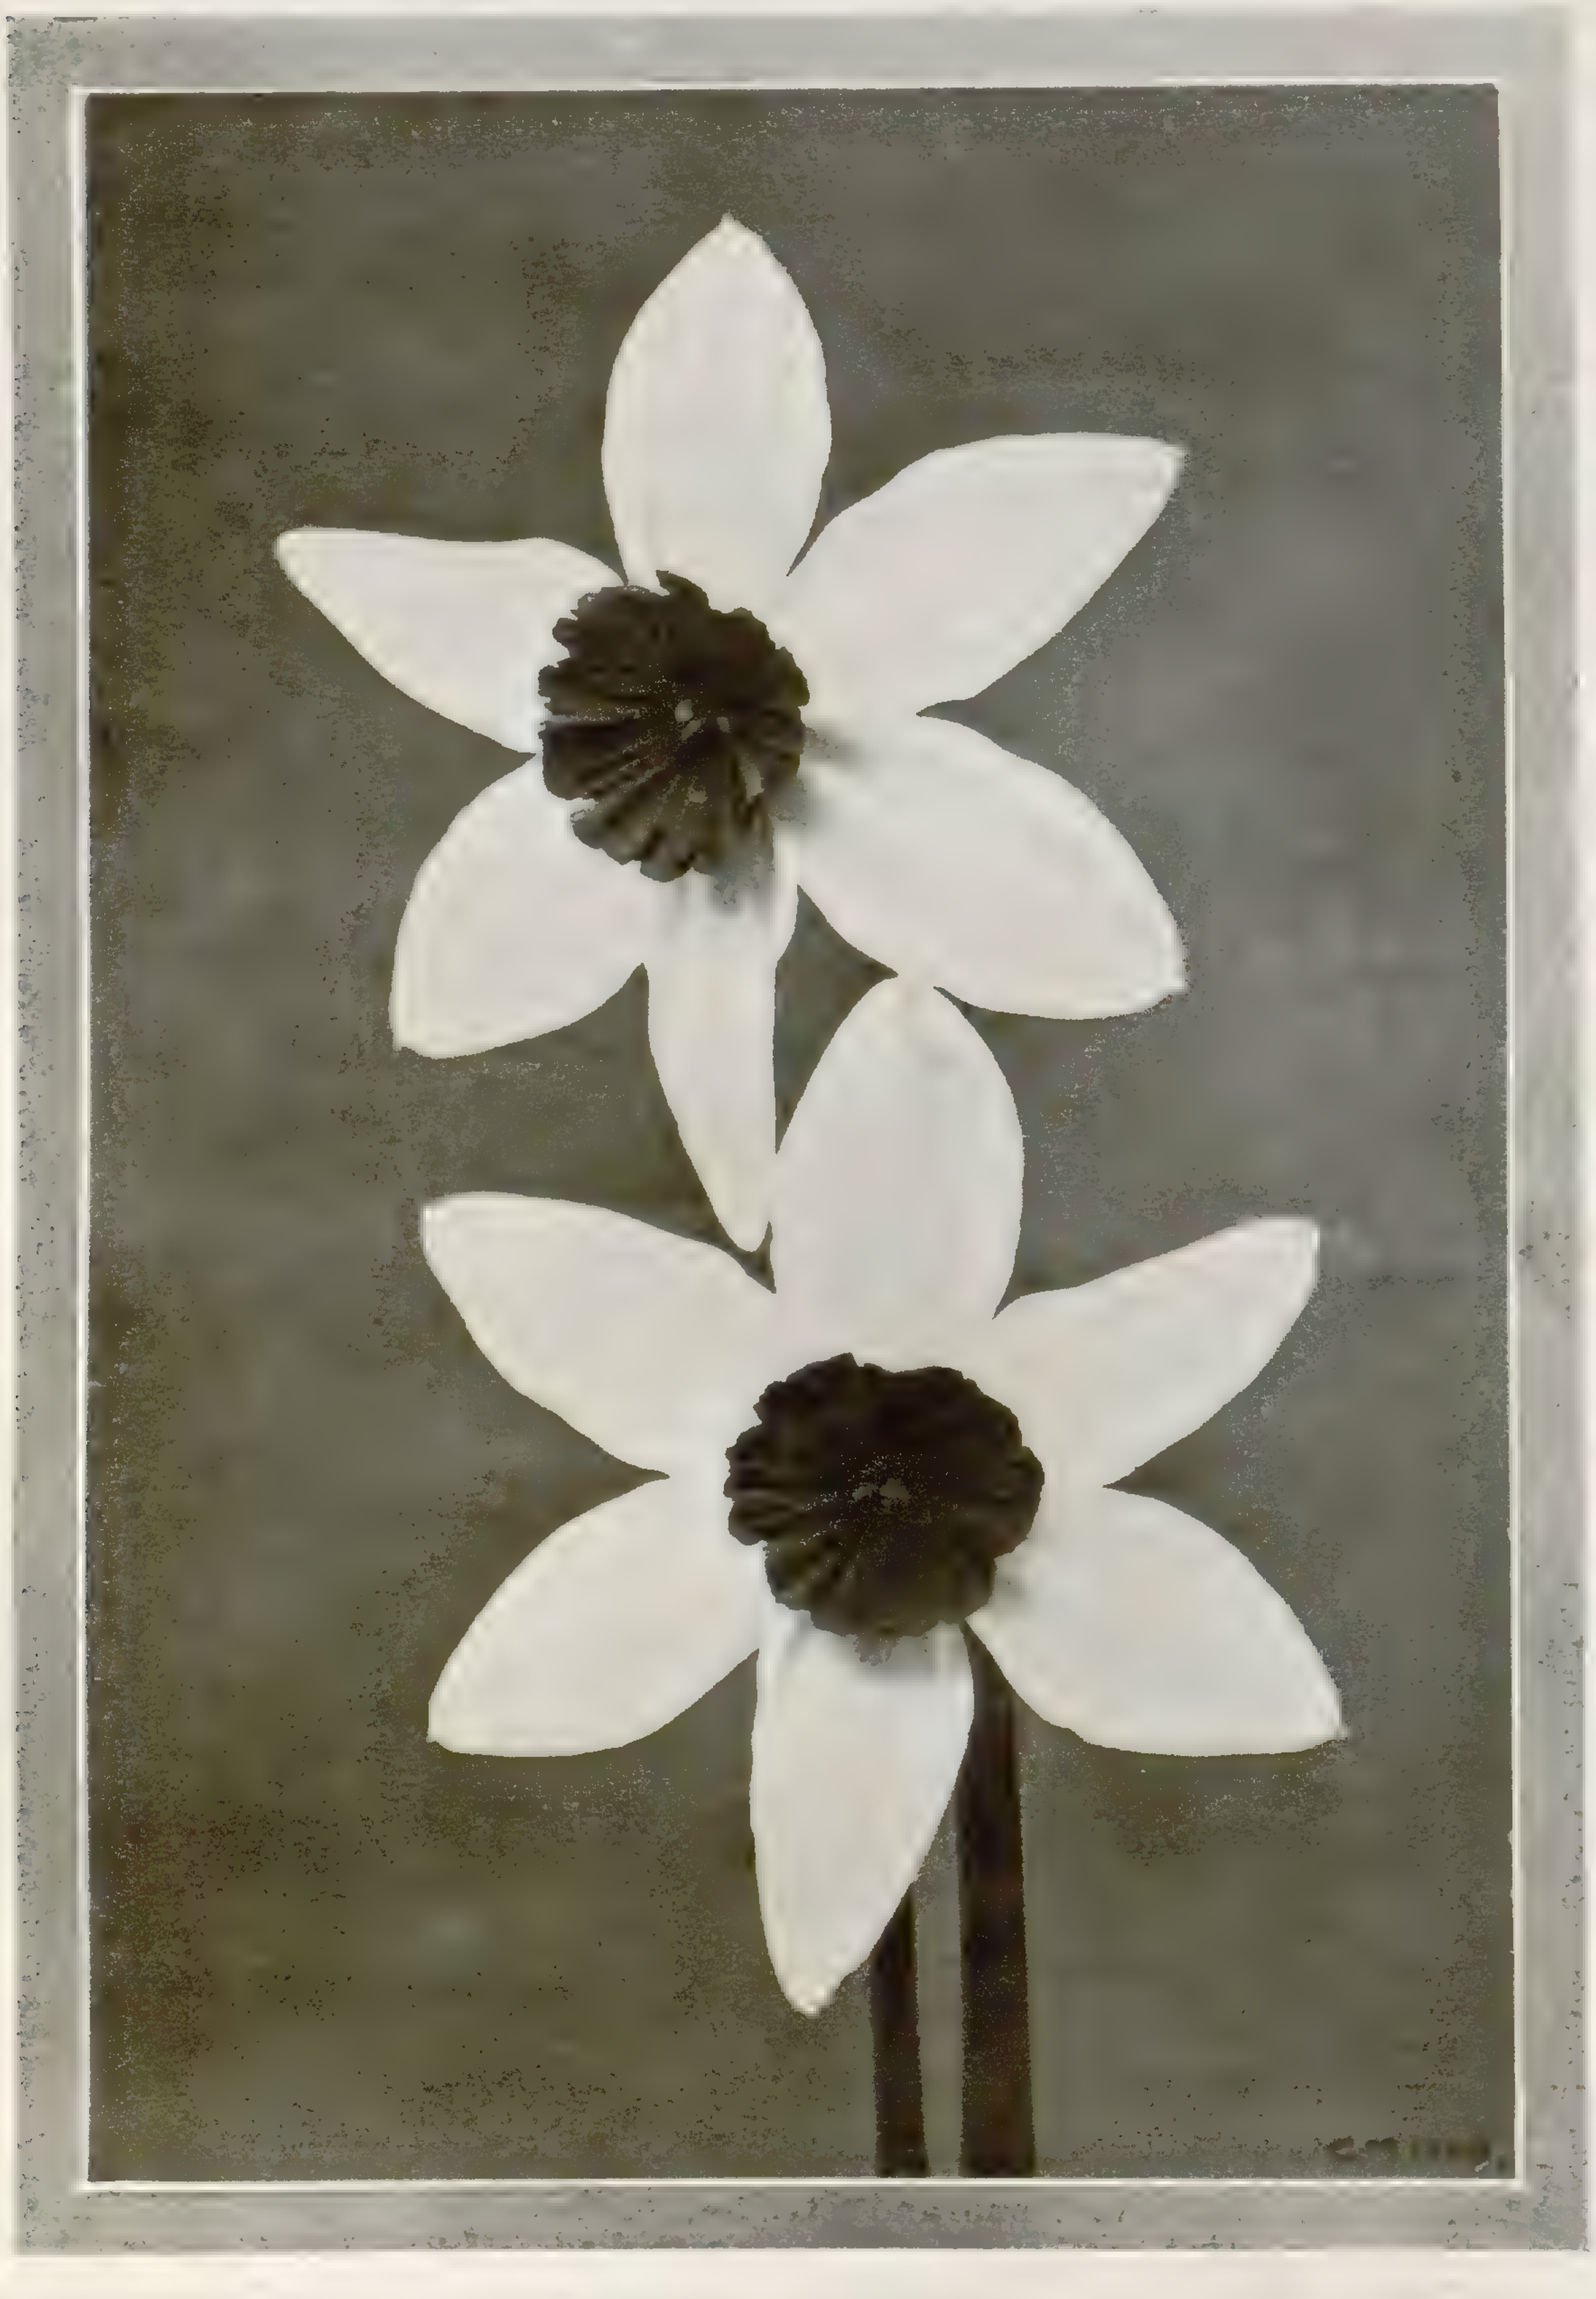
In large towns, where the price of land practically prohibits the making of pleasure grounds, the scheme of roof gardening has a value that deserves, and no doubt will receive, ever-increasing appreciation. Open-air life, the additional purity (or, perhaps it should be said, the less impurity) of the atmosphere high above street levels, the cheering influence of a sense of space, are all benefits to be enjoyed by those who can climb to the roof and find there reasons for lingering and working among objects of interest, such as plants, whether minute or stately; shrubs, whether rare or common; and trees, whether dwarfed or giant.

Large terrace houses in London often possess flat roofs, edged by stone balustrades, that are absolutely fitted for the making of gardens; similar rows of houses face the sea in most coast towns, and the force of ocean gales would not prevent the safe cultivation of numerous lovely subjects. In London the worst enemy will be the poisonous nature of atmospheric deposits; but syringings with soft soap and water have a marvellous result in keeping leaves clean and healthy.

The first study of any roof top, with a view to gardening, will consist of a series of revelations to the inexperienced worker. There are such strangely warm nooks to be discovered behind and against chimney stacks that it is possible to take a deck chair and rug and sit down in comfort to meditate over the site, and draw a rough plan of its measurements and aspects. There will also be cold places, wind-swept, or sure receivers of the first ice, that must be described on the chart. A thermometer is needed in taking and recording observations, and a comparison of its records on the same day, at almost the same moment, in twenty or thirty different places and altitudes on the same roof, will give a lesson more eloquently than could be done in words. The whole secret of roof gardening, provided that a sufficient depth of pure soil is obtained, consists of adapting the plants to their environment and position.

Borders have to be held in by boarded sides, painted grey to match stone balustrades, or brown, or green, but there is no reason why they should not be three feet deep in some situations, fitted, therefore, for the culture of shrubs, roses, climbers, and handsome herbaceous plants. It is true that permanence is not to be gained in the sense in which we can command it in Mother Earth, but surely a climbing Rambler rose or clematis, ivy or Virginian creeper, that has been a joy for three or four years, can be gladly replaced by another specimen? Any of these climbers mentioned will thrive longer still if planted in large oil casks, which affords yet greater room for root development.

Beds on the open roof spaces can be made by throwing down a heap of builder's rubbish and stones, levelling the top, adding to it a pile of turfy loam mixed with old manure, a further mound of the compost sold by florists for potting, and then banking the whole round, two feet deep, with a rockery wall of large stones, cemented together sufficiently to well retain the earth. When the summit is gently rounded off, a raised bed will be gained, in which hyacinths, tulips, daffodils, with forget-me-nots; then ivy-leaved geraniums and violas, are sure to live and blossom. The chinks of the rockery sides can be adorned by blue Scilla sibirica and Chionodoxa Lucillæ, crocuses, and small ferns, to be followed by lobelia and sweet alyssum.



NARCISSUS INCOGNITA.

A beautiful variety, with white perianth and yellow, orange-rimmed crown. The flowers illustrated were grown at the Lissadell Bulb Farm, Lissadell, Sligo.

It is always advisable to board up the inner side of the balustrade, as this prevents a draught from sweeping across the floor level; outjutting tall screens of painted wood may be of use here and there against chimney alcoves or the ends of walls to increase the geniality of the southern sides. In a deep border, by a balustrade, a row of different shrubs will usually flourish; the golden euonymus and golden privet will imitate the glow of sunshine, syringa and gorse can blossom even within the City boundaries; there may be red, rose, and white hawthorns, lilac rhododendrons, snowy masses on red stems of Prunus Pissardi, and, where the warmth and shelter are greatest, whole groups of azaleas will burst out to greet the passing of May into June.

Wonderful are the winter effects that clever roof gardeners can show: a chimney stack may be vermilion from October to February with the clustered berries of the fire thorn, and the ground beneath be spread over by the deeper red-berried branches of cotoneasters. In a square tub, set in a cosy angle, the spring-perfumed roseate Daphne mezereum will flourish, with variegated arabis above its roots. Whole rockeries of primroses, forget-me-nots, hepaticas, and double red and white daisies may appear slanted against cooler walls, and in the shadowed places may be displayed the green and yellow foliage of the periwinkle, Vinca minor variegata, glossy rosettes of London pride, and sword-grey leaves of German iris.

There should be flowers all the summer in profusion for gathering, since marguerites, asters, violas, pinks, begonias, Marguerite carnations, sweet williams, and snapdragons are but a sample of the plants that can be safely introduced, while autumn Michaelmas daisies and early chrysanthemums will flourish in deep boxes. For the supply of the home vases alone the roof garden is of immense value.

Then do we not each one of us need a solitude of peace, to which to carry our weariness, anxieties, and moods? There is a spiritual atmosphere, as well as a temporal one, about this Eden near the sky, although its vista views may be only above the housetops; we can take to it a love of Nature that is, to many, a pain in London life, and find in the crinkled primrose leaf, or unfurling violet bud, a comforting message of union between town and country, a pledge of the undying poetry of being, a forecast of the coming of a sun-power that will reveal fresh loveliness even in this man-made sanctuary.

Failures there must be among the trees, shrubs, and plants that we ask to adapt themselves to this high altitude, but these will not spoil the record of success any more than a sculptor's renown is destroyed by his wasted chip heaps. That there are millions of experiments to be tried will not deter but invigorate the work of flower lovers, who know that the perfection of roof gardening can only be earned for future men and women in a yet more overcrowded land, by the patient pioneer efforts that are made to-day. M. H.

NARCISSUS INCOGNITA.

One of the finest of the Barri group of daffodils, and especially of that section in which the perianth is white, is Incognita. This is not one of the newest varieties, but its beauty and price keep it in a high position, and yet it is within the reach of those fanciers who do not mind paying anything from ten shillings to twenty-one shillings per bulb. The flowers are of large size, and the white perianth segments are of good shape and substance, setting off to fullest advantage the showy and rather flattened crown, which is of a deep rich yellow colour, edged with bright orange, and charmingly frilled. Under good culture Incognita grows from fifteen to eighteen inches high, and as its flowers have the merit of lasting in good condition for a long time the variety is worthy of consideration. Our illustration represents flowers exhibited from the Lissadell Bulb Farm, Lissadell, Sligo, Ireland, at the meeting of the Royal Horticultural Society held at Westminster on April 11.

Euphorbia jacquinæflora.—When the young shoots on the stock plants have grown two to three inches they should be removed with a portion of the old stem attached, and have the wounded part placed in powdered charcoal or fine wood ashes to prevent bleeding. These cuttings may be inserted close to the edges of small sixty-sized pots previously filled with peat and sand in equal parts. Give sufficient water to settle the soil, and plunge in a bed with a bottom heat of 80 to 85 degrees; the propagating case must be kept close for a few days, after which a little ventilation may be afforded them each evening, as a preventive of damping, to which this useful winter-flowering plant is most subject. Should the moisture collect upon the propagating frames it must be removed daily with a sponge. If these details are carefully and regularly observed little or no trouble will be experienced.—J. D.

LAWNS.—Those who desire to make a new lawn or bowling green, or to renovate and maintain existing ones in good condition, can have no better guide than "Lawns and Greens," by T. W. Sanders, price 1s. net, by post 1s. 2d.; bound in cloth 1s. 6d., by post 1s. 9d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

NEW PLANTS, ETC.

ODONTOGLOSSUM OSSULSTONI. SHRUBBERY VARIETY.

This is a superb odontoglossum, and it was represented by a grand plant carrying a spike of nearly a dozen and a half beautiful flowers. The Shrubbery variety is the finest of the numerous forms of the hybrid between O. nobile (Pescatorei) and O. spectabile, and it gave ample evidence of the influence of O. Harryanum through the last-named parent. The largest flowers were about four inches in depth, finely proportioned, and largely of a rich purplish-maroon colour, with white tips and marks on the sepals and petals, and a white apex to the yellow-marked lip. F.C.C., R.H.S., April 11. Messrs. Charlesworth and Co., Haywards Heath.

ONCOBA SPINOSA ROUTLEDGEI.

A quite new and distinct greenhouse shrub, with deep green lanceolate leaves, spiny branches, and beautiful glistening pure white flowers, each about 2½ inches across, and with a large central cluster of rich yellow stamens and anthers. The oncobas form a small genus of the order Bixineæ, and the typical O. spinosa is regarded as a native of Arabia, but O. spinosa Routledgei was found, we understand, in Central Africa by a gentleman who was hunting big game, and the seeds were sent by him to Mr. Shea, in whose garden plants flowered in two years from seed sowing. As the plant flowers freely it may become of considerable horticultural value. F.C.C., R.H.S., April 11. Chas. E. Shea, Esq., Foots Cray, Kent.

NEPHROLEPIS MARSHALLI COMPACTA.

In this most elegant fern we seem to have reached the acme of plumose development, fineness of division, and "mossiness," on the part of the variable Nephrolepis exaltata. It is a very beautiful fern, and a well-grown plant forms one of the most charming presents one could make to a lady. This variety formerly secured an A.M. F.C.C., R.H.S., April 11. Messrs. H. B. May and Sons, Edmonton.

MILTONIA BLEUANA VAR. LAEKEN.

This is a striking and a remarkable variety, but by no means so beautiful as M. B. nobilior and some other varieties of M. Bleuana. The plant shown carried three spikes of large flowers, and on the white ground the purplish-rose colouring was laid rather heavily on the base of the sepals and petals, and, in lighter shade, appeared on the centre of the broad lip. F.C.C., R.H.S., April 11. Mr. Firmin Lambeau, Brussels.

PELARGONIUM MAXIM KOVALESKY.

This is said to be a fine bedding variety, and if it proves so to be, then it has a great future before it, as the colour is at once distinct and striking. The flowers are of large size, and borne in large, compact trusses. The colour is light yellowish orange. Indian yellow is perhaps the correct shade, and one we have not hitherto possessed in bedding pelargoniums. As a pot plant the variety will also be useful, but the flowers do not possess that wonderful development of size and form that so many of the splendid Swanley seedlings show, consequently it will depend on its colour and suitability for bedding for its popularity. A.M. R.H.S., April 11. Messrs. H. Cannell and Sons, Swanley.

ROSE MARCELLA.

A new hybrid tea rose of considerable promise and great beauty; the well-formed flowers are light flesh-pink, charmingly brightened by a suffusion of light yellow that shades up from the base of each petal. The flowers are of large size and good substance. A.M., R.H.S., April 11. Messrs. William Paul and Son, Waltham Cross.

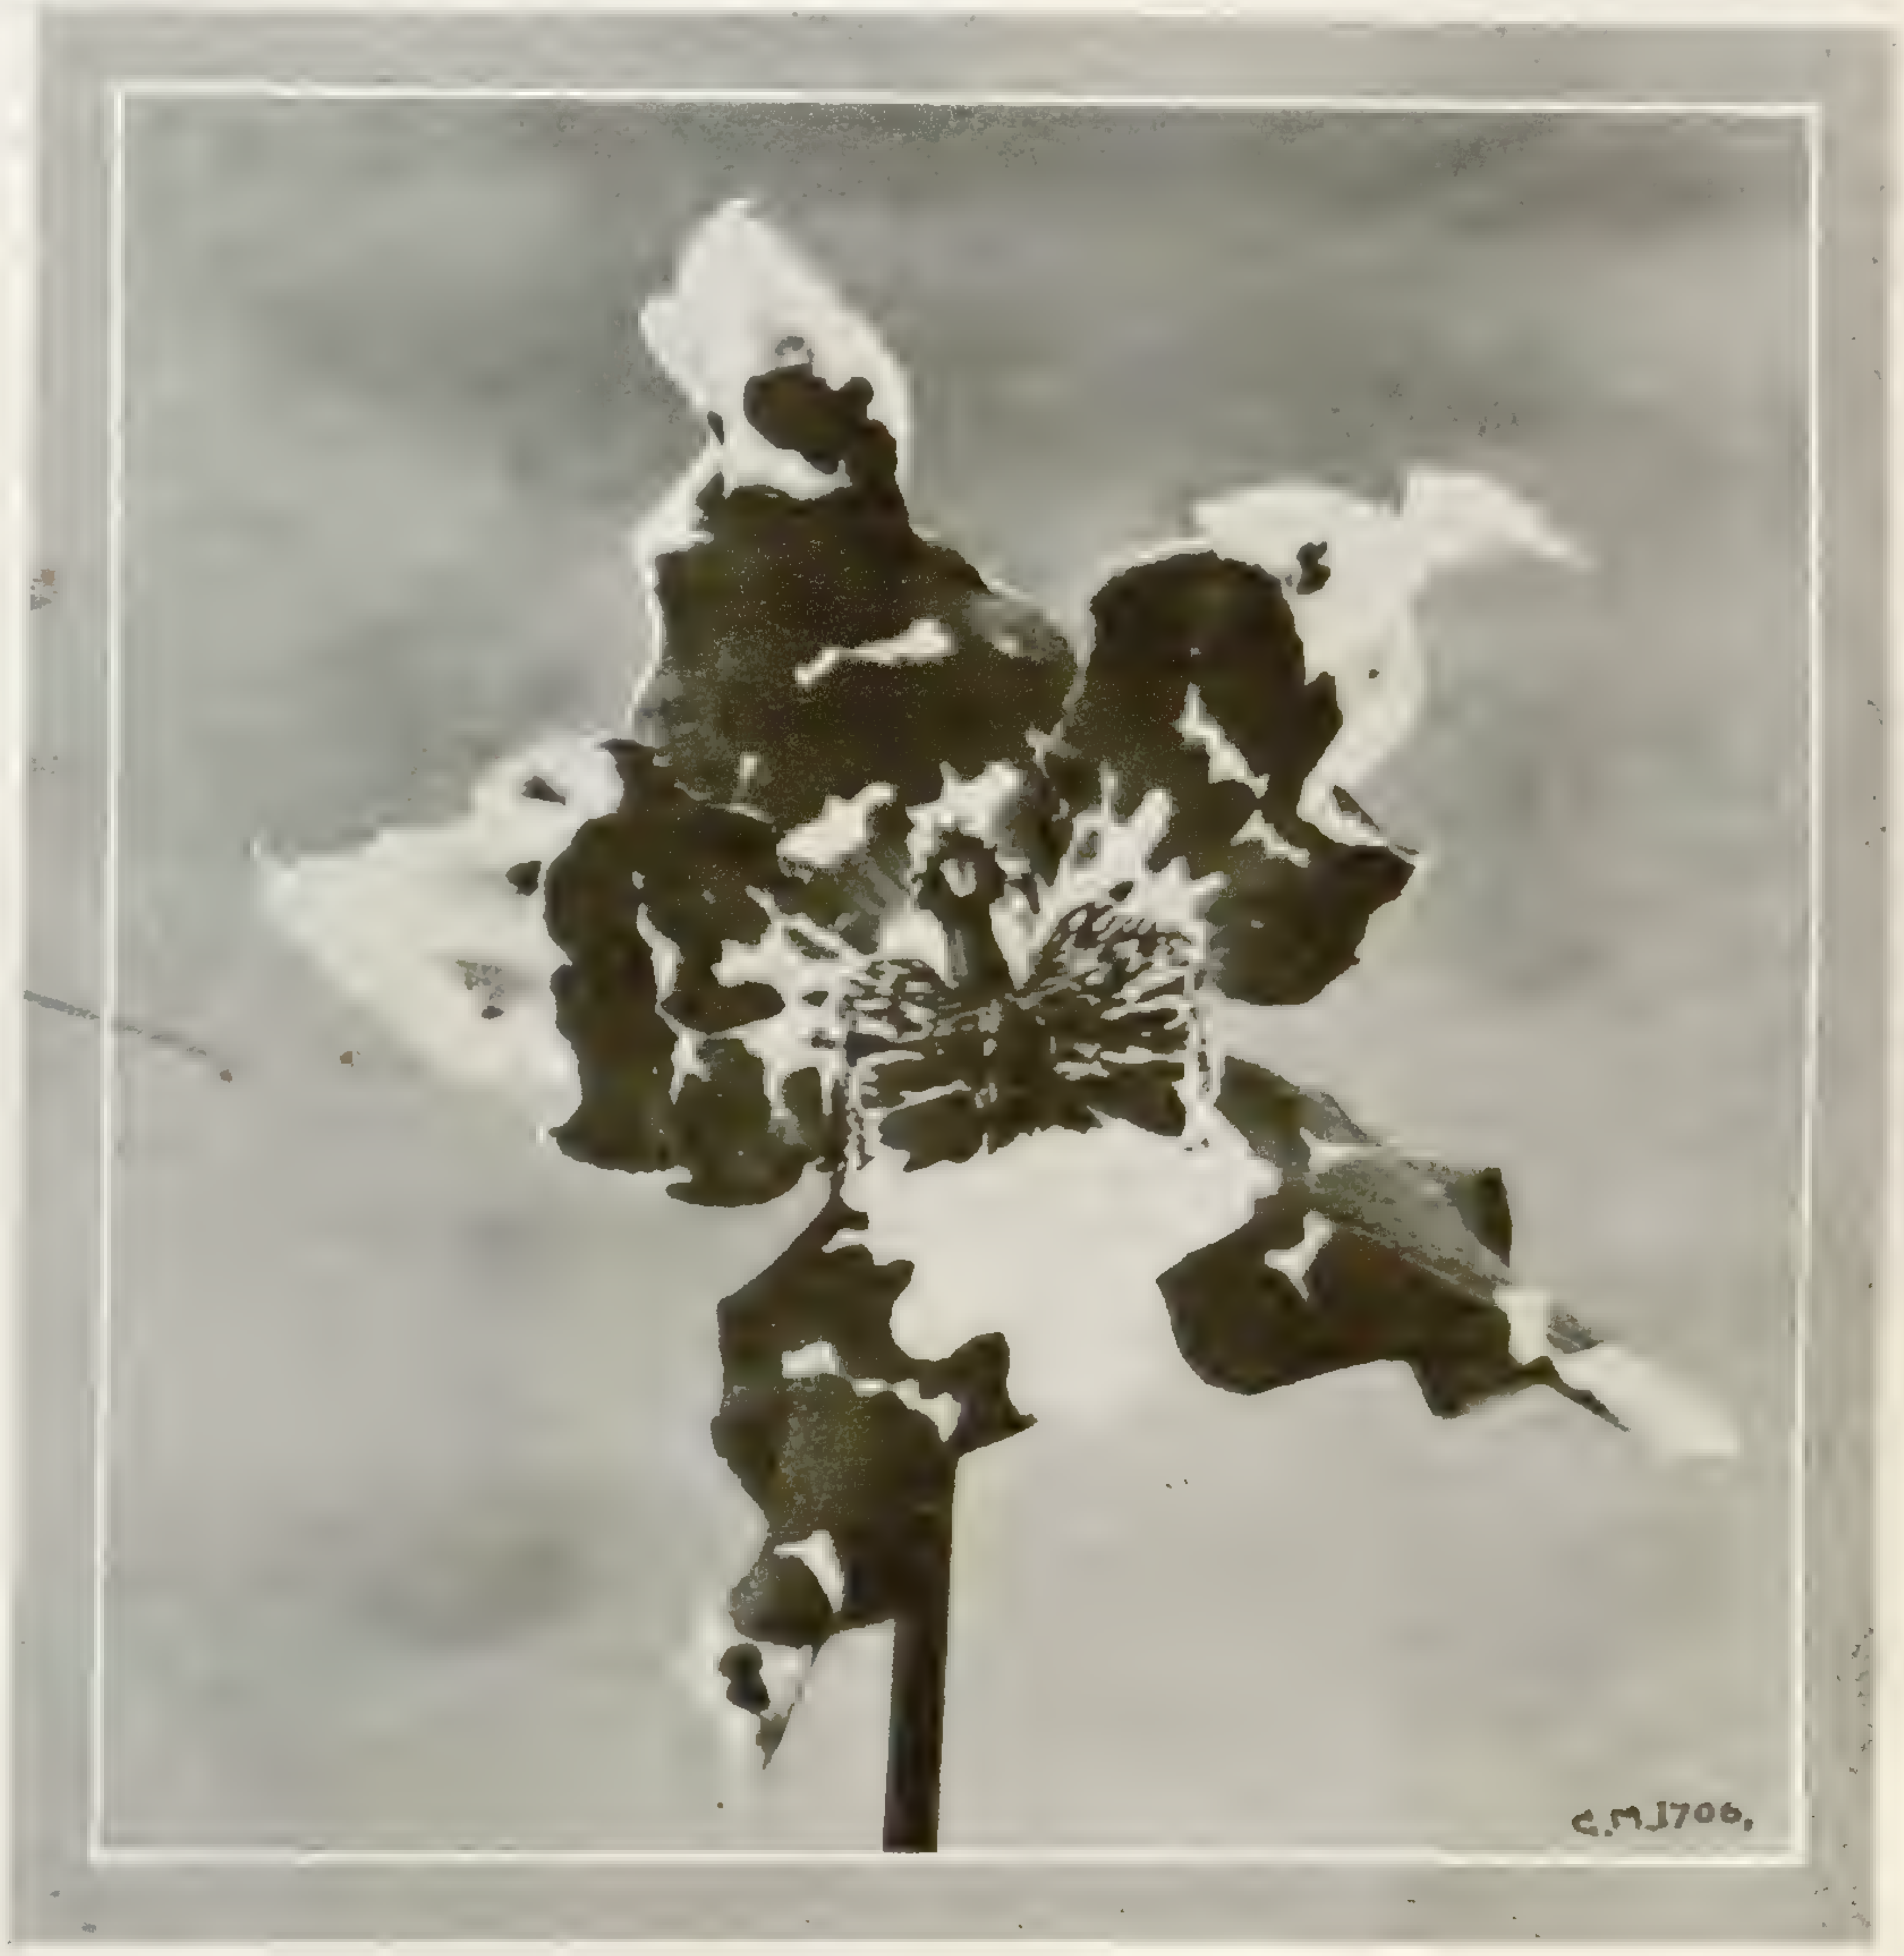
AURICULAS.

Mrs. Harry Veitch.—A beautiful auricula of fine form and size, and a good grower. The flowers are a brilliant shade of rich old rose colour. A.M., R.H.S., April 11. Mr. Jas. Douglas, Great Bookham.

Mrs. Gardiner.—This very pretty and effective variety produces a fine truss of shapely flowers that are a beautiful shade of pale lilac, almost a lavender tint. A.M. R.H.S., April 11. Mr. Jas. Douglas, Great Bookham.

SINGLE DAHLIAS.

During the summer of last year a special trial of single dahlias was conducted for the National Dahlia Society at Messrs. J. Cheal and Sons' Nurseries with a view to selecting the most suitable effect for the garden. Some sixty or more of the finest varieties in general cultivation, with a considerable number of novelties, were included in the trial, and the committee of the society, after making a critical inspection of them, selected the following as being the best in their several shades of colour for the production of a rich display of colour. It is a point of some interest that these varieties include some of the best single dahlias for exhibition.



ODONTOGLOSSUM OSSULSTONI SHRUBBERY VARIETY.
Flowers rich purplish-maroon and white. F.C.C., R.H.S., April 11.
Messrs. Charlesworth and Co., Haywards Heath.

Amy (Mawley).—An excellent variety with refined flowers of a rich terra-cotta hue.

Ensign.—An effective variety with brilliant scarlet flowers of fine form.

Butterfly (Cheal).—Distinct and pleasing, the flowers white with primrose band round the centre.

Columbine (Girdlestone).—A variety that has long been in cultivation, and still the best in its colour, which is rich rose with a suggestion of orange at the base of the florets.

Cardinal (Cheal).—A quite new variety which received a F.C.C. from the N.D.S. and an A.M. from the R.H.S. for its merits for exhibition, as well as the three marks for garden decoration. The flowers are cardinal-red with golden band round the centre.

Fugi San (Cheal).—Rich golden-yellow, the centre encircled with a crimson ring.

Kitty (Cheal).—A distinct and beautiful variety, the colour rose-mauve, the florets darker at the base.

Lady Bountiful (Seale).—A charming variety, the colour rich pink with crimson band round the centre.

Leslie Seale (Seale).—Bright silvery lilac, the disc encircled with a deep crimson band.

Miss Morland (Cheal).—Crimson-scarlet, effective and of high quality.

Miss Roberts (Ware).—An exceptionally fine yellow variety, remarkable for its rich colour and high quality.

Mrs. Joynson Hicks (Cheal).—A new variety of much value for its fine form and distinct colour, this latter being pale buff, with crimson ring round the centre. F.C.C., N.D.S., and A.M., R.H.S., for exhibition, and three marks from the N.D.S. for the garden.

Mrs. W. Hood (Dobbie).—A rich yellow flowered variety of much merit.

Morning Glow (Seale).—A fine flower, the colour amber with broad scarlet band round the disc.

Owen Thomas (Cheal).—Very effective, the flowers large, crimson-scarlet, tipped with golden-yellow.

Peggy (Cheal).—A distinct variety with well-formed flowers, coloured purple-rose, orange and crimson.

Rosy Gem (Dickson and Robinson).—A pretty variety with flowers of fine form and a pleasing rose colour.

Rosebank Scarlet (Mawley).—Flowers brilliant scarlet and produced with remarkable freedom.

Snowdrop (Cheal).—A pure white variety of great excellence.

Vesuvius (Cheal).—An effective variety with orange-scarlet flowers.

STIGMONOSE AND PERPETUAL-FLOWERING CARNATIONS.

This disease is one of real danger, and not simply the slight disfigurement of the leaves, as it has been the wont of the majority of private and commercial growers to regard it. In appearance it is simply small, yellow translucent spots on the leaves, which are, in reality, destroyed cells. These are seen plainer when the leaf is held up to the light, or in the early spring of the year, when the plants are making a very rapid growth. The spots are also very noticeable upon the young leaves of certain varieties. The course the disease takes is, that as the leaf develops, so the spots enlarge until they run together, then finally the leaf turns yellow and dies.

AURICULA MRS. GARDINER.
An effective variety with large lilac-coloured flowers. A.M., R.H.S., April 11. Mr. James Douglas, Great Bookham.

These spots may be caused, in the first place, by thrip, red spider, aphids, etc. We look upon them as present memorials of a past evil, and this is where we have been wrong. It has been the undoing of many varieties already, and unless steps are taken we shall see such stand-byes as Enchantress, etc., falling a prey to the ravages of stigmonose.

The theory of what we will call the new disease is simply this: After the insect has withdrawn its proboscis from the young leaf, it leaves a poison in the leaf cells, which, under favourable conditions becomes a permanent disease. That these punctures are primarily the cause of this disease I have no doubt, and I think it quite possible that this poison may grow and permeate the whole plant and its cuttings, regardless of fresh punctures, providing that the health of the plants had been weakened by indifferent cultivation or old age.

I hold that the development of the disease greatly depends upon the condition of the plant at the time, and the after-treatment received. Naturally, varieties with a robust constitution, whose foliage is deep and rich in colour, and what seems to me as being most important of all, plants grown in a light, airy house, are better able to resist the attack and throw off the poison deposited in their system. On the other hand, in the case of a plant which has been grown under unfavourable conditions, and naturally suffering from a weakened constitution, the poison left in its system is able to gradually permeate its tissues, and unless better culture is given to those particular plants and their offspring, they will become most unprofitable to their owner, producing a yellow spotty growth, poor bloom, and only a very indifferent crop.

To illustrate my meaning and convey this new idea of stigmonose, I would cite the case of the variety Enchantress. Those who remember this Queen of Carnations when it was first disseminated, know that at no time of the year was its foliage marked, unless, of course, the plants had been neglected and allowed to become blighted. But I venture to say now in the early spring it is quite the exception that one sees a stock entirely free from this disease. The reason for this is, no doubt, owing to its rapid and succulent growth, which naturally would make this variety in question a prey to the ravages of this particular disease.

A quite common theory, and one which I personally favoured until quite recently, was that these yellow translucent spots on the leaves which, as a rule, were most general and much more conspicuous in the early spring, were caused by the sun. Now I maintain that the sun does not cause the spots, but in its natural course builds up the chlorophyll in the leaves, and so causes the disease spots to become more conspicuous.

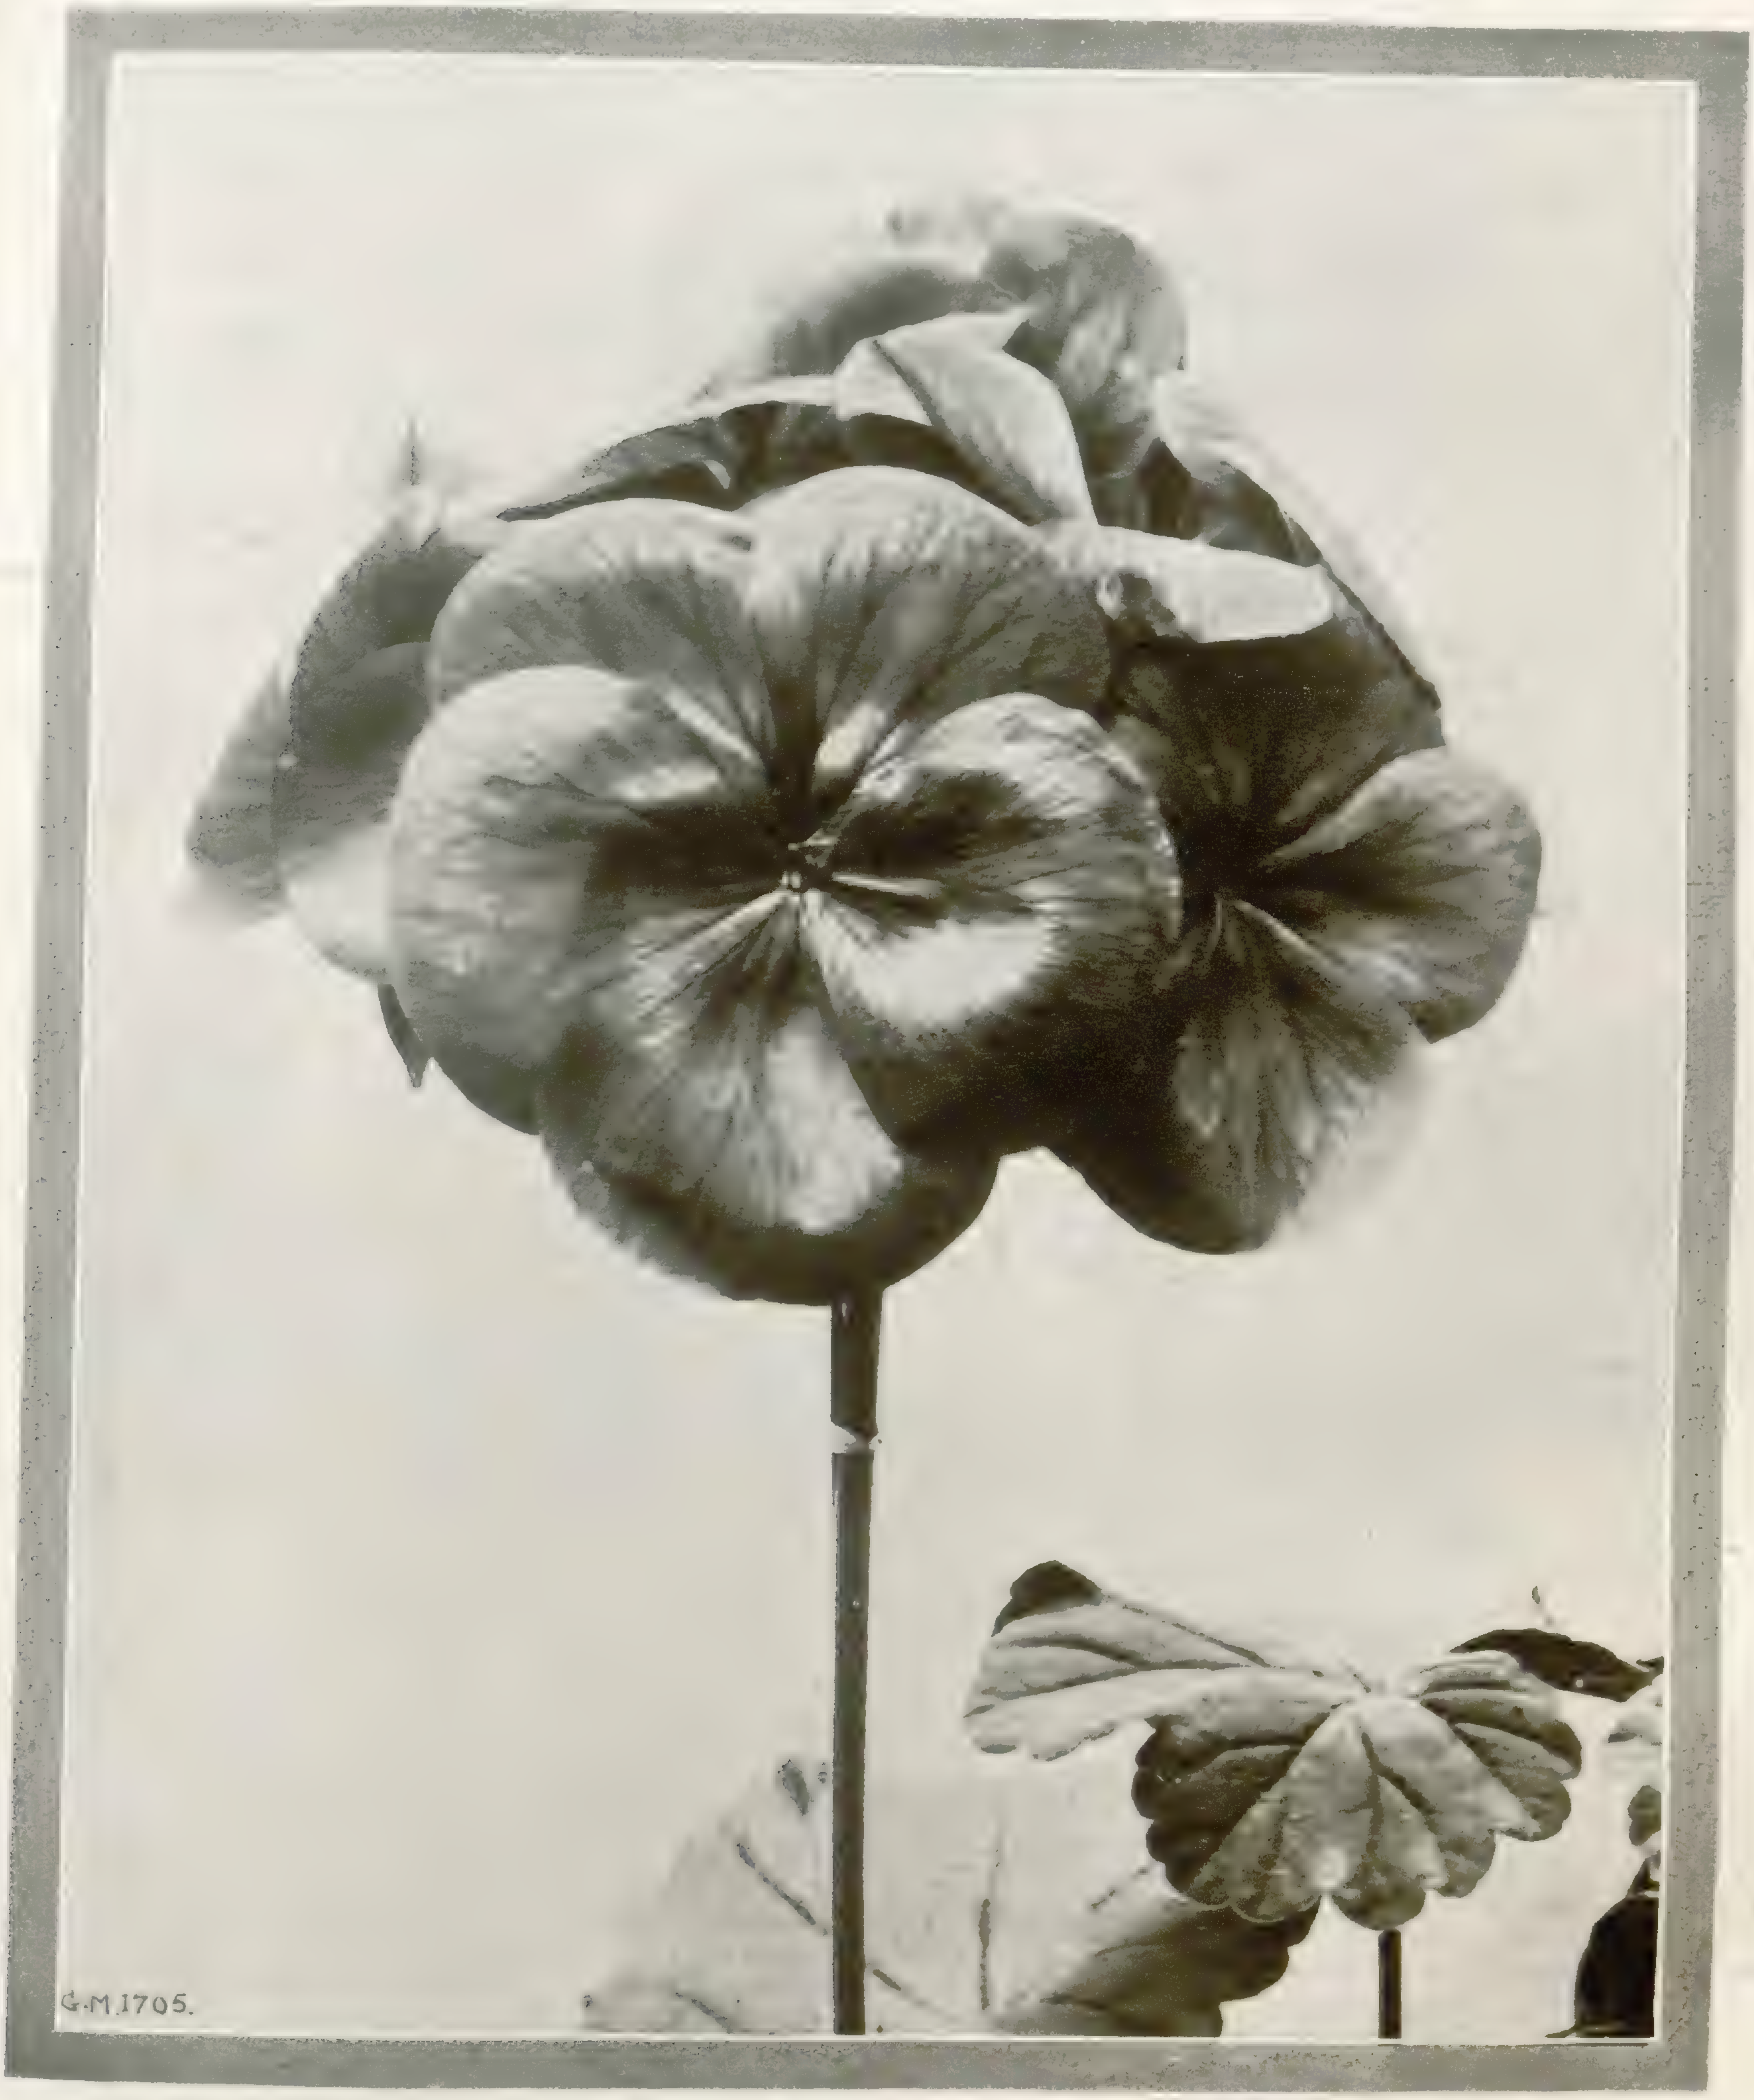
The means by which we can exterminate this disease are many. First, endeavour to raise varieties with more robust constitution, and hence better able to resist its attack, or rather the attack of its allies. Keep the plants as free as possible from all insect pests. Take the greatest possible care in the selection of cuttings, not only the cutting itself, but the actual parent plant. Grow the plants in as light a house as possible, with as much air as is conducive to a slow, hard growth. Give a moderate diet, and water with care and discrimination. Under such conditions, with unerring care, it will take three years to purge a variety of this disease, so that in the case of old varieties it is really not worth while to try and restore them to their own original state of health, particularly because of the large number of new improved varieties competing for place.

We cannot too fully realise the wisdom, or rather the absolute necessity of discarding the old varieties of carnations, for the perpetual-flowering carnation quickly deteriorates after being in commerce for several years. This is well known to all who raise and grow seedlings, as well as to the large market growers who remember Mrs. T. W. Lawson or even Enchantress in their palmy days.

Montagu C. Allwood.

Herbs.—The herb garden at this season will require to be thoroughly overhauled, and the stocks of the various kinds taken into consideration. Some may require to be reduced, and those that are scarce be multiplied by division or propagation. Beds may also be sown now of seed of sage, thyme, tarragon, etc., and also of the annual kinds, such as basils, chervil, etc.—C. Flack.

SILVER-LEAF IN PEACHES.



PELARGONIUM MAXIM KOVALENSKY.
A new bedding variety of Indian yellow colour. A.M., R.H.S., April 11. Messrs. H. Cannell and Sons, Swanley.

A few years ago I was much troubled with silver-leaf in plum trees growing on a wall three hundred feet long. The wall had been specially devoted to plums for generations, and I found, on taking charge, that many trees were old ones. The garden in question was made in 1717. Some of the oldest plum trees were badly affected with silver-leaf, and nothing that I could do seemed to have any effect upon the disease; so I rooted up all affected specimens, well limed the soil, and planted young ones.

I have just read your reply to a correspondent—"A. S., Lyndhurst"—in your issue April 8, and it has induced me to write this note. There are peach trees under my notice here that are affected with silver-leaf, and, although the disease has not shown itself at all in previous years, I am firmly convinced that the trees have been affected by it for several years past. The garden in which these trees are growing was formerly a portion of an old nursery, and I find that fungus is very general in the soil and other kinds of plants suffer through it. What the general treatment of the soil has been in the past I do not know, but I do know—and many other gardeners also know—that in these days chips are used wholesale as a bedding material for cattle, horses in particular. Scores of tons of manure, full of chips, is used in nurseries and private gardens to my knowledge, and I feel sure that the soil so treated will, in the future, be a hot-bed of fungus.

When I served my time to gardening I was instructed to carefully clear away all prunings and wood generally from the surface of the soil, and never, on any account, dig in the prunings, as fungus would result. Now, we find gardeners burying chips by the ton. The matter is a serious one, and I should much value the opinions of pathologists who contribute to your pages on this subject.

Geo. Garner.

THE REVIVAL OF THE PENTSTEMON.

The past few years, so full of horticultural progress, has witnessed a marked advance in the culture and improvement of the pentstemon. The pentstemon has long had a place in English gardens, though not always holding quite so high a position as now. I remember the florists' pentstemons of fifteen years or more ago were not only inferior in size of blossom and spike, but decidedly poorer in colourings than those we now possess.

In the best strains of the present day the washy hues are almost entirely eliminated. The lilacs, dull pinks, and motley purplish shades are practically non-existent. The pink and rose shades are clearer, purer, and brighter, the crimsons are richer, and less heavy in tone, the scarlets much more intense and brilliant, while the pale forms are clearer and more pleasing than in the past. We have still with us maroon, purple, and other deep hues, but these are good in their rich and decided shades, and are of value as contrasts. The improvement in size of blossom is doubtless the result of continuous selection, leaving but the finer forms to continue the race. That the pentstemon is rapidly becoming a fashionable subject is obvious.

Pentstemons are ideal plants for associating with roses, especially for grouping under standards or half-standards, or for massing in the foreground of a rose screen or series of arches. With lilies they are very effective, especially if used as a groundwork, with tall lilies of the tigrinum, speciosum, or auratum groups rising boldly through them. Massed in beds or borders, without the addition of any other subject, unless it is an edging of violas or pansies, pentstemons are the equal of any late summer-flowering plants, and the superior of most.

In beds and borders of pentstemons it is well to specialise in certain colours, and this brings me to the distinctive Gem type of pentstemon. Many gardeners acknowledge the value of Newbury Gem, an attractive pentstemon of undoubted hardiness in the majority of gardens, but the intending planter should choose the new Southgate Gem to secure the best in this particular bright colour. The effect of a mass of this brilliant scarlet-crimson, with white throat, is very striking. In the pink shades afforded by these light-habited pentstemons, Myddleton Pink, a graceful carmine-pink, with white throat, is finer than Pink Newbury Gem, though the latter is also valuable, while a variety under the name of Holland House Gem has equalled Myddleton Pink, in form, beauty, and freedom, the difference being that the throat is marked with rose, and the pink has a tendency towards a salmon tint. White Newbury Gem is not pure enough for extended use. We want a good clear white in this section. When secured it will be one of the most valuable garden plants one could possess.

There are several forms of P. campanulatus in cultivation, though none of them offer any striking note of colour. The type gives various shades of rose, but there is too much tendency to purple in the blossoms. The variety atro-purpureus gives a decided violet-purple, but, though really graceful, it is not a good colour. P. Kellermanni, said to be a specific form, is nearly akin to the latter in habit and colour, which is a deep maroon-purple; it is a very recommendable plant to those requiring sombre tones for contrast.

It would hardly be of service to give a list of the best show pentstemons, as the raisers in different localities have often the same varieties under different names, but a few especial good varieties are Gertrude, Don Juan, Juliet, White Giant, George Home, Le Prophete, Sir Trevor Lawrence, George Ulrich, Cordelia, Romeo, Princess, and Albert Durer.

In the matter of culture, deep digging and good manuring should go hand in hand. Top-dressing in summer is not necessary if the soil is good and the hoe is kept going. Finally, in an open situation, uncrowded, and well staked with light bamboos, the pentstemon, in its revived beauty, and new forms, will prove one of the greatest attractions of the garden.

P. S. HAYWARD.

HARDY PLANT CHAT.

Arends' Astilbes.

Those who have seen the varieties of the hybrid astilbes raised by Herr George Arends, of Ronsdorf, Germany, at the Temple Shows and at other places, have been much struck with their value for the garden, yet I think they are even prettier when grown under glass, and thus protected from the weather. This remark specially applies to those varieties with pink flowers, which, of course, predominate in the Arends' astilbes. Yet it is almost impossible to overestimate the worth of some of these hybrids for the open garden, and those who have suitable places by the margins of ponds will do well to study the effect of the different varieties in such places. The astilbe delights in a good deal of moisture at the roots, although when in flower the beauty of the inflorescence is much shortened by rain followed by strong sun. With plenty of moisture at the roots, however, the astilbes generally assume a much prettier aspect than in an ordinary border, and those who cultivate the newer nymphæas in their gardens and grounds will do well to study the effect of the two plants when associated. Some consideration of the colour tints is necessary, and one can see, for example, that the new Astilbe Venus, which has violet-rose flowers, and grows from three to four feet high, would jar badly in its colour tones with some of the deeper-coloured nymphæas, such as Ellisiana or Robinsoniana, although going well with some of the finest of the white or yellowish ones. But, as plants for moist gardens, or even for drier ones, where plenty of water can be supplied to them in the growing season, these charming hybrids ought to be looked after by lovers of the best of the graceful astilbes and spiræas.

Astrantia carniolica.

The Masterworts do not appear to rank too high in the estimation of the ordinary cultivator of hardy flowers, yet one finds an increasing appreciation of their good qualities among those who are best acquainted with them. Doubtless they are but dull in the garden, and there are few of these astrantias which can be called really bright enough to make a border gay. Yet they are liked for cutting where bright hues are not requisite, and the formation of the flower and the tints it possesses, even in the case of the least brilliant of the species, call for a good many encomiums from those who have studied these points.

A good plant is not to be despised, and for cutting purposes we have few flowers which will last longer in water than these masterworts. Probably the brightest of all these plants is A. carniolica, which has flowers that have been fairly well described as of a clear rose-pink, and this colour, with the peculiar arrangement or formation of the flowers, give it a special claim upon us. It is not generally known that the astrantias belong to the umbelliferous plants, and that the blooms conform to the usual arrangement of the flowers of this order. Astrantia carniolica is, therefore, commended to those who would like to own one or two of the best of these plants, not only because of the formation of the flowers, but also because of their intrinsic beauty and value. The uses of this and other astrantias are increased by the fact that they grow well in shade, even in that of deciduous trees, while the foliage itself is neat and pretty.

Salvia argentea.

I observe that a little boom is appearing among the salvias or sages, but those who are inclined to take part in it will do well to consider that the number of first-class border flowers in the genus is comparatively limited, although they certainly afford the keen hybridiser many opportunities for distinguishing himself, as, so far as I know, nobody has seriously taken up the hybridisation of the salvias. In the species called S. argentea we have an oldish plant which has been known to me for many years, and I have occasionally seen it grown in small and narrow borders—a position where it is quite out of place. The leaves, which are handsome without a doubt, being of a fine silvery hue, are too large and spreading for the small border, although the total height of the plant when in bloom—about three feet admits of its inclusion in such borders. The branching heads of white flowers are not much in themselves, and the main beauty of this salvia, to me, lies in the handsome foliage. It is a plant which looks exceedingly well in the wild garden if planted where its leaves are not hidden by taller subjects, and a little group by some path in the more open part of the woodlands is very pleasing. This silvery sage seems to call for no special treatment, and those who seek for such subjects may purchase it with safety in spring or early autumn.

The Spring Satin Flower.

Now that the improvement of many well-known hardy flowers is going on apace—a rate of progress which will certainly be accelerated by the operations of the National Hardy Plant Society, somebody might well turn their attention to raising improved forms of the lovely spring Satin Flower, Sisyrinchium grandiflorum, which generally gives great delight to all who grow it, as it sends up from above its grassy leaves its stems carrying such lovely satin-like, lustrous bells of purple or white. An old plant, it is not a common one, though cheap to purchase, and very beautiful when in bloom. I was in the garden of a famous artist recently, and was pleased to see that he had been including a good many plants of S. grandiflorum among his garden treasures, and I am confident that it only requires to be better known to become again more popular. The typical purple form is charming, and I like it even better than the white one, albus, although some are of a different taste. One thing may be remarked, which is, that this sisyrinchium does not like to be carpeted with any other subject, and flowers better if left without any other plant about its "feet." By the way, the accepted name of Satin Flower is undeniably to be preferred to the odious one of "Swine's Snout," at one time prevalent.

S. ARNOTT.

CAMPANULAS FOR THE HERBACEOUS BORDER.

Campanulas, or bellflowers, are among the most useful of hardy subjects for the herbaceous border, as they grow readily, flower abundantly, have much variety of growth and flower, are readily propagated, and generally appreciated because they give a full crop of blossom over a long period. While some campanulas grow but a few inches high, others reach as high as six feet, therefore they may be used for all parts of the border. Even the low growers can be accommodated quite at the front of the border, on slightly raised hillocks, or as an edging to the border itself, where a permanent edging is not provided in the shape of grass, box, or tiles.

Campanulas are found in many countries; some few species are British, notably C. persicifolia, C. glomerata, and C. pyramidalis. Some exotics have been cultivated in this country upwards of two hundred years, perhaps longer. While many varieties can be grown from seed, the most certain method of propagation is by division, as they are easily increased in this way in spring, and a quite small portion with a root attached will grow readily. Some of the more rare or weakly-growing kinds are best propagated in cold frames.

Deeply dug ordinary garden soil, well enriched with manure, will grow the stronger-growing kinds quite easily, while some of the dwarf growers need a little more attention as to soil and drainage; the latter, in stiff soil, is important. In no case is it wise to allow the plants to remain on the same site without replanting for more than three years, as they become exhausted, and without robust progress the flower crop cannot be good.

The following varieties are useful, interesting, and attractive, and, as a guide to intending planters, I attach the approximate height of growth to each. C. persicifolia is the most common type, yet distinctly useful; it is thoroughly hardy, grows freely, and produces its single blue flowers in abundance; 2½ feet. C. p. alba is similar in every way, except save colour, which is pure white; 2½ feet. C. p. Moerheimi has large semi-double white flowers: 3 feet. C. p. Daisy Hill, semi-double lavender blue; 3 feet. C. p. alba grandiflora (Backhouse's), snowy-white, extra large single flowers; 3 feet. C. p. Porcelain, pale porcelain blue; 2½ feet. C. Van Houttei, a fine hybrid, with long blue bells; 2 feet. C. amabilis, a new and distinct species, from the Crimea, large light blue flowers; 2½ feet. C. boninensis, a slender-growing species, with numerous pale blue flowers; 3 feet. C. b. alba, similar except in colour. C. carpatica alba, white; 1 foot. C. c. Riverslea, deep blue, vigorous habit: 1½ feet. C. Fergusoni, large cup-shaped flowers, pale blue; 2 feet. C. glomerata dahurica, rich deep blue; 1½ feet. C. Hendersoni, with mauve-tinted flowers; 1 foot.

C. lactiflora, has its flowers milk coloured, tinged with blue, borne in erect loose panicles; 4 feet. C. grandiflora (platycodon), a hardy Chinese species, with deep blue balloon-like blossoms; 1½ feet. C. g. alba, pure white; 2 feet. C. g. Mariesi, a dwarf-growing blue form; 1 foot. C. alliarifolia, a choice kind, of pyramidal habit, the broad leaves are greyish and the long-tubed white flowers have serrated petals, and hang on gracefully arching stems: 2½ feet. C. Burghalti has long silky flowers of a lavender-blue tint; 2½ feet. C. latiloba (grandis) is a stately species, midway between persicifolia and pyramidalis, rich blue; 3 feet. C. macrantha produces royal purple trumpet-shaped flowers in pyramidal spikes; 4 feet. C. m. alba is a white form of the above. C. patula is a free-flowering species with nodding blue flowers; 1½ feet. C. pulcherrima is tall and floriferous, bearing deep blue, reflexed, bell-shaped flowers, valuable for the wild garden; 3 feet.

E. Molyneux.

Brachycome iberidifolia. — Scarcely anything more charming or capable of yielding such a prolonged display can be found among annuals than the various forms of Brachycome iberidifolia, commonly known as "The Swan River Daisy." It is a dwarf half-hardy annual, and is best raised from seed sown in a cold frame, and transplanted to flowering quarters in the open, where it forms an admirable edging or groundwork plant, and may also be used as a carpet in bare places among shrubs. It succeeds in a light, rich soil that is well drained, and in the sunniest exposure. The plant attains a height of some nine inches, and the flowers are most suggestive of some small stellate form of cineraria. The colour ranges from white to deep purple, one of the most effective shades being a pale lavender-blue. Unlike so many of our best annuals, the strain of seed production appears not to adversely affect the flowering, as the plants always maintain a good display until cut down by frost in autumn.—Thomas Smith.

CARNATION DUCHESS OF DEVONSHIRE.
A new crimson perpetual variety, distributed by Messrs. Young and Co., Hatherley, Cheltenham.

CARNATION DUCHESS OF DEVONSHIRE.

It is remarkable how great an attraction a carnation has if it has a considerable resemblance to the Old Clove. A deep crimson flower is always admired, and when exhibited nearly everyone smells it with a vague hope that it will be as fragrant as the old garden favourite. There are now several good deep crimson perpetual carnations, but there is always room for a first-rate variety. The new Duchess of Devonshire, introduced by Messrs. Young and Co., Hatherley, Cheltenham, is already receiving a great deal of attention at the hands of growers of perpetual carnations because of the fine size of the blooms and their deep and yet bright crimson shade. Long stems and a good calyx are additional merits, and the variety is free flowering. Messrs. Young and Co. have been exhibiting this variety finely for some time, while at the recent North of England Horticultural Society's show, and at the Royal Horticultural Society's meetings, the variety has been displayed in excellent form. Both in the North and in the South the variety has been regarded with considerable favour.

FOLLOWING NATURE'S LEAD

"It won't do here." How often does one hear this remark in reference individually to a host of plants which flourish like the proverbial bay tree under certain conditions, and either absolutely refuse to grow in others, or merely linger. I am not referring here to plants introduced from other lands, but native subjects, both utilitarian and otherwise, and in respect of them the sentence quoted above is no mere idle expression, but proof of the fact that though Nature is kind, she will not be dictated to. If trees, shrubs, and plants would succeed in all places the same gardening would become a simple matter, but the fact that such-and-such a thing will not do here or there offers possibilities to the gardener, who brings skill to bear in order, if possible, to make them do. Does he succeed? This question might be answered in a hundred gardens to-day, the owners of which have indicated that they would like to have such-and-such a thing, which, in the ordinary way, would not do, but by altering conditions so as to make them as favourable as possible they have been induced to flourish.

It may be said in all sincerity that the gardener does not prove his skill in growing things for which local conditions are in every way suited so much as in the cultivation of subjects which, to use the expression again, will not do, or will not do very well, and in obtaining good results, with Nature opposed to him, as it were, he proves himself to be an expert. What private gardeners can do in this direction is extraordinary, provided they have employers who are patient and do not complain about the cost, but the commercial grower who adopts this attitude of fighting Dame Nature and making things do is on the wrong track. He has got to live out of what he grows, and the plan for him is to take Nature as his teacher, let her indicate where things will do, and, having settled on the favoured spot, grow them to the best of his ability. Just why a certain plant will flourish here, and not there, very often presents a problem which the experimentalist may try and master; but the commercial man must take things as they are, follow Nature's lead in fact as to what he shall grow and where he shall grow it.

It is owing to Nature's way of adapting certain localities for certain things that great horticultural industries have centred themselves in certain districts. On visiting a locality where some crop is grown profitably one might be disposed to try it elsewhere, and, in the light of an experiment, this would be all very well, but it would not be wise to put any money into the venture without having some reasonable indication that it would succeed. Whether we have missed opportunities through taking too much for granted in this respect is another matter, and, as a case in point, it was thought for a long time that Holland, and only Holland, was the place for bulbs, but it has been proved since that bulb growing can be carried on in certain places in old England, and Nature will aid their culture. Speaking of this matter, I am reminded of a district on the borders of Gloucestershire where in the early spring the land is yellow over with flowers of the single daffodil. Where this bulb is a weed would not the same conditions be suitable for growing other forms of this lovely flower commercially? No one has tried it, so far as I know, and perhaps here there is a missed opportunity.

One day, not long ago, I was talking to an enthusiastic amateur who was bemoaning the fact that his garden would not grow asparagus. How much money he had spent on his bed I should not like to say, but he had dug out the soil, put in drainage, made up the bed after the elaborate manner described in books on the subject, and planted the best of crowns, but the asparagus only lingered, and if the man only reckoned up what each head that has come to table as yet had cost him he would probably be frightened. Now for the contrast. The next day I was in another district, and saw an agricultural labourer working amongst his asparagus on a twenty perch allotment, turning up great clods of the stiffest of soil with a two-pronged fork. There had been no elaborate bed-making there; in fact, the man knew nothing about asparagus, except that it grew well round the district, and he had been induced to put in a few crowns, which did so well that he planted the whole of his twenty perches with the crop, and was hankering after a bit more land for the same purpose. In other words, he had followed Nature's lead, a bit blindly, if you like, but, nevertheless, with profit to himself.

There are peculiarities about plums which are not easily explained, and particularly in regard to varieties. Commercial plum culture is confined largely to certain areas dotted about the country, and in most of these you will find, in addition to well-known varieties that can be obtained from any nursery, local plums which are peculiar to the locality. Take, for instance, the Pershore, or egg plum of Worcestershire, which propagates itself from suckers and grows like a weed in its own locality. Not a high-class plum, you will say; perhaps not, but the Worcestershire folk have followed Nature's lead in growing this plum, which she gave to them, and it is questionable whether there is another that pays better, taking one year with another. Years ago, I don't know when, there originated in a tiny little village in Gloucestershire a local plum known as the Blaisdon Red, and to-day, along the Severn side, you may see acres of them, all grown from suckers, though I do not remember ever seeing the variety elsewhere. Here is another case of Nature's lead being followed, and where people plant the Blaisdon Red they know it will grow, and do its share towards paying the rent.

As with plums, so with damsons, which show strong likings for some districts in preference to others. Most people must have heard of the Cheshire damsons, which seem to have size and flavour all their own, but Cheshire is not the only county in the Midlands that is famous for damsons, for I know a district in Staffordshire, overlooking the valley of the Dove, where every farm and small holding has its damson orchard, and many of the hedges which divide the fields are lined with damson trees. Mind you, they are damsons, too, these natives of the Midlands, the fruits being large and fleshy, and, when in good condition, fit for any dessert table. Propagation is a simple matter as the trees are increased readily by means of suckers, and I know of no fruit which, taking one year with another, pays so well, and costs so little. The Staffordshire farmer or small holder who looks to his damson trees to pay part of his rent—they may pay it all in some seasons—can take no credit unto himself for the cultivation of the fruit; he simply follows Nature's lead by planting the trees with which she provides him, and the rest is left to the favoured condition of the locality.

The mixed medley of trees which make up a Staffordshire damson orchard present a different appearance to a cherry orchard in Kent, and if the Kentish cherry grower does a great deal more than the Midland farmer, first in arranging his trees in symmetrical rows, and afterwards paying attention to them in matters of pruning and cultivation, the cases, contrasting though they may be in many respects, are alike in the matter of following Nature's lead. What would be the good of trying to establish a cherry orchard in the damson-growing district of North Staffs? The thing would necessarily be a failure, and the reason why Kent practically holds a monopoly in the matter of cherry growing is because Nature has selected the hop county as being peculiarly adapted to the fruit in question. Let the cobbler stick to his last, says the old proverb, and, in the same way, the Kentish man may stick to his cherry growing, knowing that in the establishment of orchards where trees will grow he is doubling the marketable value of the land.

Just one more instance of Dame Nature's lead being followed, and this time I would take the reader to the famous Cheddar Valley in Somerset, where the cheese comes from, but perhaps more noted in recent years for the earliness of its strawberries. Summer visitors who drive out to see the famous caves and cliffs of the Cheddar Valley, also see strawberry patches situated in all sorts of situations, where, in some cases, it has been necessary to make the ground at the outset, and a novice might be inclined to wonder why strawberry culture should be made an industry in such a district. Well, it is all a story of following Nature's lead. It might have been an accidental discovery in the first place to find that Cheddar strawberries came finer and earlier than those in other parts, but be that as it may, the Cheddar folk have not been slow to take advantage of the lead which Nature gave them, and have established an industry which is lucrative, and grows in importance. If the Cheddar strawberry growers had never found out the advantage that Nature gives them, what a splendid opportunity would have been missed!

H.

Medinillas. — Where well-grown examples of the handsome Medinilla magnifica are found they cannot fail to command appreciation. Their flowers are produced in graceful drooping panicles, forming at once a charming floral display which the handsome foliage renders most effective. Medinilla magnifica is an extremely gross feeder, and where space is available for its full development the plants must be afforded ample root room and be placed in a light position. Large specimens are undoubtedly the most effective, and flower in great profusion. Cuttings may be rooted at this stage when it is desirous to increase the stock, and they should be removed from the parent plant with a heel of the old wood when the shoot has developed about six inches of growth. If these are inserted in a brisk bottom heat of 80 to 85 degrees they will readily take root. A liberal application of the syringe on bright days will assist in keeping down red spider and other troublesome pests. As regards the potting compost loam and peat of best quality, in equal parts, will be found suitable, adding sufficient lime rubble and Bedfordshire sand to keep it porous. As soon as the larger flowering specimens are growing freely, with abundant root action, give liberal applications of diluted farmyard manure, with an occasional top-dressing of some approved artificial fertiliser.—J. D.

MAINTAINING THE BALANCE

Pruning is a subject upon which there are most diverse opinions held, and on no portion of it is this so much the case as concerning the advisability of pruning or non-pruning trees the year they are planted. As "G. H. H." rightly observes, there will probably always be this difference of opinion, based on the pruner's experience and his success or failure with either method.

Now, in my opinion, we are all agreed that the determining factor is the state of the roots; "maintaining the balance" means, in the opinion of its exponents, shortening the top of the tree in a corresponding degree to that which the roots have experienced by the spades of the lifters in the nursery. Whether this is sound doctrine from a botanical point of view, I will leave in abler hands, but apparently, according to the results experienced by "G. H. H.'s" friends, it is not altogether borne out in practice.

To come to practical experience, which is often the only safe thing to go upon in these matters, we are ourselves convinced first-year pruners, having never seen the slightest ill-effects attend such a course in an experience of upwards of fifty years. Standing by itself, this fact would seem absolutely contrary to the former writer's experience, but there is something else to be said, which, in my opinion, explains the seeming contradiction somewhat.

We always raise all our trees at home on a piece of light land; further, we keep them constantly shifted, so that when the time comes for planting they have a mass of fibrous roots of much greater extent than it would be possible to send out from a nursery unless each tree were bundled solely by itself. In this case, there is no question of a large amount of the roots being removed, so that "maintaining the balance" does not come in; in fact, the state of the tree is almost as if it had never been moved, and indeed for purposes of pruning behaves exactly so.

Whether we should still succeed as first-year pruners with trees which had not such an extensive root system, I very much doubt. This idea, "maintaining the balance" is a very pretty one; nothing seems simpler than this, that, because a certain portion of the roots which feed the top have been removed, a corresponding amount of the top should also go in order that the remaining roots should not be overtaxed.

Apparently, however, there is another factor which enters into the situation which to some extent alters matters. Just as the call for an extraordinary effort often brings out some hitherto latent power in the individual, so the greater demand upon the roots seems to increase their activity, and consequently their extent. Naturally, there are limits within which this is true, the relation between top and root must not be allowed to assume such proportions that the latter cannot provide the necessary water, etc., to maintain life in the top. If, however, this can be maintained, as far as my experience goes, the larger amount of top, calling for increased energy on the part of the roots, stimulates their activity and produces a larger root run.

This was brought to my notice very forcibly some years ago by some root-grafting experiments in which I was interested.

Small portions of fibrous roots of plum stocks and broad-leaved paradise apple stocks were grafted on to pieces of wood, "laid in" by the heels in sand in a shed during the winter to callus, and then planted out in the spring. The pieces of root were only about a couple of inches long, and about ⅛ inch in diameter. By far the best results were obtained when the roots were put on to pieces of old wood upwards of three feet long and an inch or so in diameter, rather than pieces of wood of the current year's growth a foot or so in length.

It seemed almost impossible to me, at the first sight, but I have lifted and examined many of the trees and their roots since, and can vouch from experience for the facts stated above. I regard this as an exaggerated example of the principle I have tried to enunciate, viz., the greater the demand within reasonable limits, the greater is the effort to respond to that demand. When, however, the tree is pruned the amount of wood dependent upon the roots is reduced to half, perhaps less, with correspondingly less reflex action on the roots.

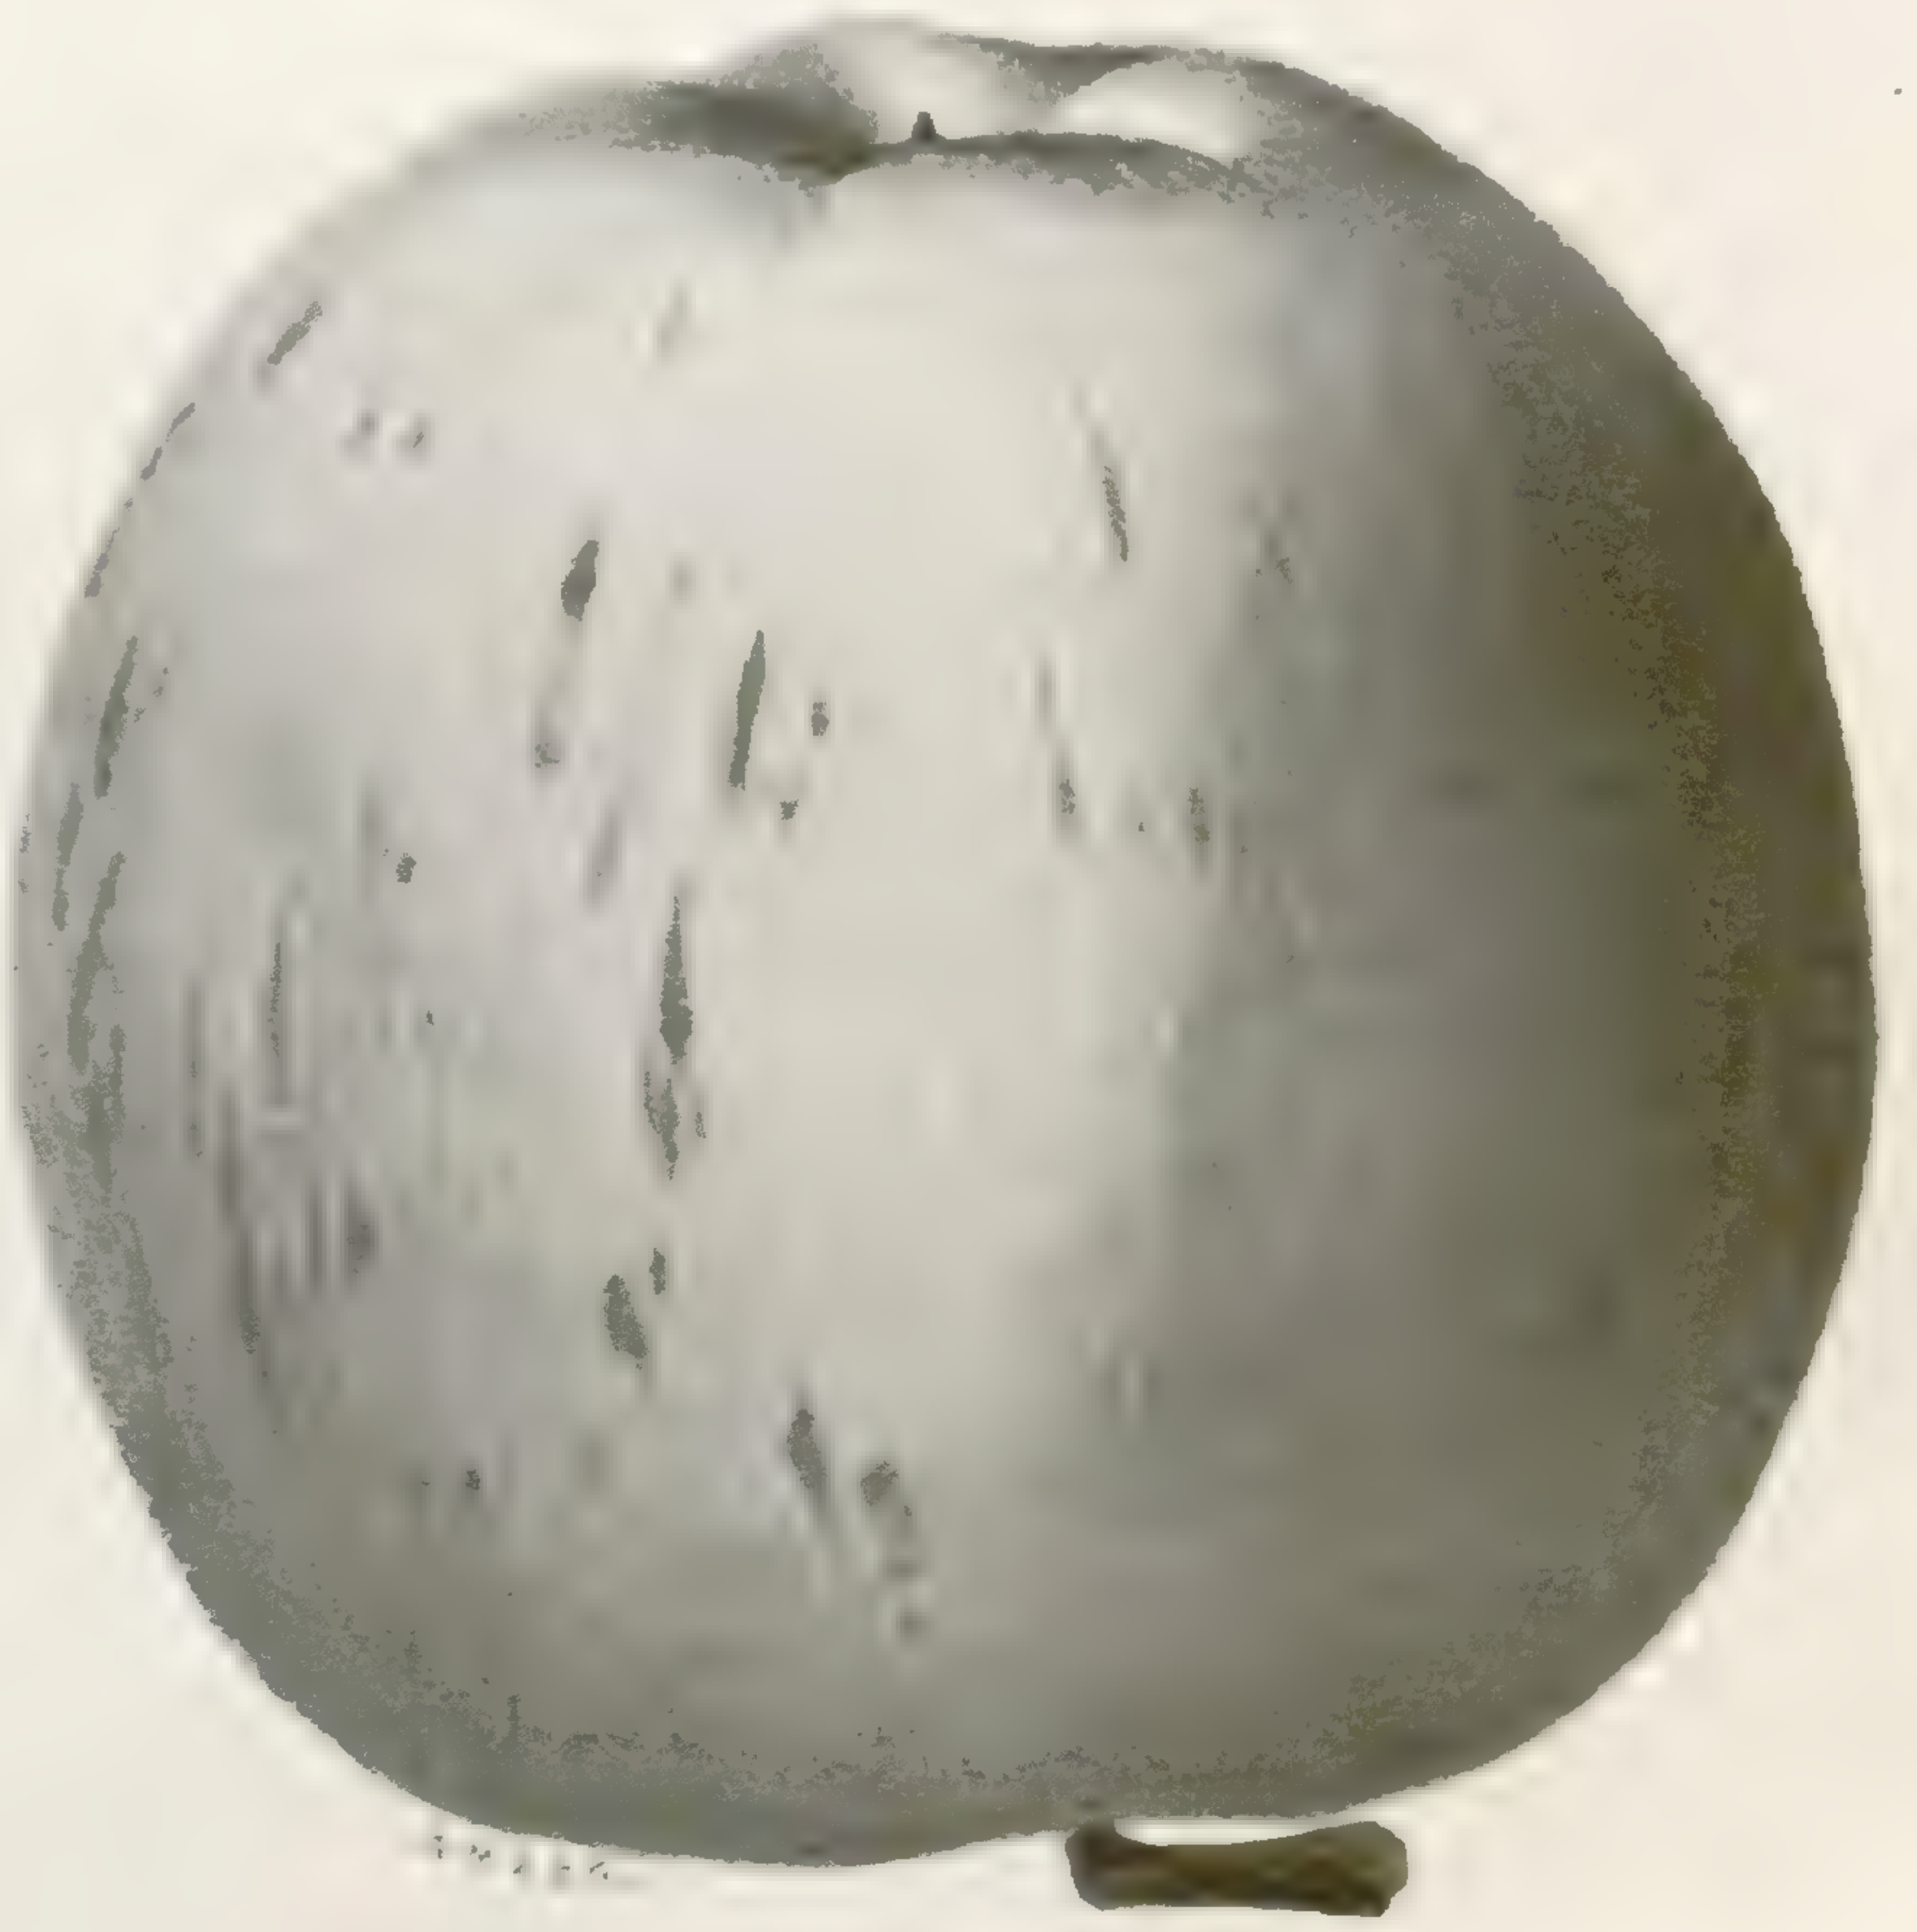
Not only so, but the area of leaf surface is probably reduced to a far greater degree, so that the roots also lack their assistance in the production of carbon and also in elaborating the sap for their use.

Another point that still further hampers the pruned tree whose root system is bad, is that the lower buds, which are almost the only ones left after pruning, are mostly dormant buds, the breaking of which must cost the tree very much greater efforts to produce the necessary leaves and shoots than the more natural wood buds at the top—that is to say, on the portion pruned away. This difficulty, coupled with the considerably reduced leaf area, must be a severe handicap to the pruned tree, even without that caused by the reflex action I spoke of first. These are a few of the reasons by which I have tried to account in my own mind for what is an undoubted fact, viz., that many trees, particularly those planted late and with bad roots, are far better left unpruned the first year, and afterwards, the succeeding year, pruned to much the same point as one would have cut to the first year.

F. W. Hammond.

APPLE BOW HILL PIPPIN.

From time to time we have drawn attention to apples and pears of outstanding merit, but which have not, so far, achieved a full measure of popularity. Some varieties do far better in some localities than others, and this is the point we would emphasise. It is not possible to deal with all these excellent fruits in these pages at planting time, as the needs of others besides fruit specialists have to be studied regularly. We hope, however, that our readers will during the ensuing season make notes of the behaviour of Bow Hill Pippin apple, and kindly report to us, as we feel convinced the variety is of unusual merit. The fruits are large and handsome, and somewhat like those of Peasgood's Nonsuch in appearance. The tree bears well, but is best cultivated in bush form. Useful alike for culinary and dessert purposes, Bow Hill Pippin is in use from October to February. It was raised, we believe, by Mr. A. C. White, a noted Kentish hop grower, and that it possesses considerable merit may be gathered from the fact that the Royal Horticultural Society has conferred upon it an Award of Merit, and a First Class Certificate was granted it at York some time ago. Most of the leading nurserymen who cultivate fruit trees list the variety, and have shown good fruits of it, therefore Bow Hill Pippin is a variety to be made note of with a view to future planting.



APPLE BOW HILL PIPPIN.

A useful and handsome variety, suitable both for culinary and dessert purposes.

Jacobinia chrysostephana.—This beautiful winter-flowering plant has been so frequently shown within recent years that it must by now be familiar to nearly everyone. The crown-like heads of orange-coloured flowers are so charming that it is surprising its merits were not recognised directly after its introduction from Mexico, some forty years ago. Such was indeed far from the case, for in the course of time it nearly dropped out of cultivation, till more recently a revival set in in its favour. When first introduced it was regarded as a stove plant, which was perhaps the reason that it did not make the headway that one might expect, for grown in a stove it is not nearly as satisfactory as under cooler conditions. —W. T.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

COOL HOUSE ORCHIDS.—Plants of Odontoglossum Rossi and O. R. majus which have recently passed out of flower should be examined for the purpose of ascertaining whether they require repotting. Where the compost is in a decomposed state it is advisable to repot the plants, but while there is ample root space, and the potting compost is in a good state of preservation, it is not desirable such plants should be disturbed. This odontoglossum is not the best subject to become re-established, and it takes a considerable amount of care to retain the pseudo-bulbs in a normal plump state, and the leaves from decaying after repotting. We find the plants do best grown in shallow, well-drained pans, with a small bulk, not more than an inch deep, of potting compost, this latter consisting of two parts fibrous peat to one of broken leaves and finely chopped sphagnum moss. The compost should be pressed firmly about the base of the plants. Water after repotting, thoroughly wetting the compost through, and suspend them in a position near the roof glass where they may be carefully shaded for a time, and where they may derive the greatest advantages from the moisture in the atmosphere.

O. ROSSI HYBRIDS.—The hybrids that have been derived from the influence of O. Rossi partake in most cases of the dwarf habit of this species, and they are best grown under the same conditions as the other odontoglossums, but should at all seasons have a position within a short distance of the roof glass. We find that unless the pseudo-bulbs become thoroughly ripened, they continue to throw new growths instead of flowering, and even in cases where they do bloom from a soft immature pseudo-bulb the flowers produced are by no means satisfactory.

ODONTOGLOSSUM HARRYANUM.—The plants of this useful species are now commencing to produce new roots from the base of the developing growth. It is just at this stage that the plants may best be attended to for any repotting that may be necessary. If the roots are permitted to extend far from the base of the new growth before repotting they are the more liable to be injured in the process. It is surprising the rapid progress made by this species when a suitable position is given it. I have found that it is advisable not to over-pot the plants, and to shift them annually, using a pot just large enough to contain the roots comfortably. It will often then be found that they may be gradually shifted on as required, without having to disturb the old compost much. They are best accommodated in well-drained pots, using chopped bracken roots as drainage, the compost consisting of about equal portions of fibrous peat and osmunda fibre, with a few broken leaves and chopped sphagnum moss intermixed, with sufficient broken crocks and sand added to render the compost porous. I consider the failures in the culture of this species are due to the plants being subjected to a low temperature during winter. They should be retained in a temperature of about 55 degrees during the winter months.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CHRYSANTHEMUMS.—Plants intended for the production of large blooms should now be ready for a further shift into 32's. The compost should be of a coarser nature, and consist of good fibrous loam, leaf-soil, and silver sand, with an addition of a little bone-meal and soot. If the loam is of a retentive nature, a little lime rubble may be mixed in to assist drainage. In potting, the soil must be made nice and firm without being hard; after potting, replace the plants in the frame, and keep rather close for a few days. Syringe as often as possible. When growth has re-commenced, gradually increase the ventilation until the lights may be left off altogether, preparatory to standing the plants outside. At this stage watering must be undertaken with great care. It is advisable to examine the plants two or three times a day in this respect, for under no circumstances must they be allowed to become dry, and, on the other hand, the new soil must not be kept too wet before the roots have penetrated it. Stopping must be regularly attended to in order to secure the best results from each particular variety. There can be no fixed date given for this operation, as it varies according to variety and locality. Prevent insect attacks by occasional fumigation. Continue to pinch as required the shoots of plants of the decorative or bush type.

GREENHOUSE CALCEOLARIAS.—These most showy plants are now developing their flower trusses, and should be given assistance with some approved artificial manure. When applying the manurial matter, be careful not to let any touch the foliage, as the leaves are very soft and easily injured. Do not employ artificial heat, but endeavour to grow them as cool as possible. Shade from sunshine is absolutely necessary. Greenfly is very troublesome to these plants, and must be kept in check by fumigation, which should be light.

FUCHSIAS.—Specimen plants, if treated as advised previously, will now be ready for repotting. Use a fairly rich compost, and pot moderately firm. As the plants grow the shoots must be stopped from time to time in order to secure a shapely plant; but this must cease at least seven weeks before the plants are required to flower. Cuttings may be rooted now for giving a display in the autumn.

CLIMBERS.—As these are now growing freely, the young growths must be regulated. Avoid overcrowding by removing all weak shoots. Tying should be done regularly to endeavour to give the plant a neat appearance.

THE CONSERVATORY.—At this time of the year, when there is such an amount of flowering plants in hand, there is a great tendency to overcrowd the conservatory. This is a fault to be carefully avoided. A light, graceful appearance is what should be aimed at, and plants should be staged so that the beauties of each may be seen individually as far as is possible. Keep down the temperature by damping the paths occasionally, and admitting a little air at night to preserve the flowers.—H. Grubb, Porters Park Gardens.

HARDY FRUITS.

THE FRUIT CROP OF 1911.—It may be somewhat early to predict, but if we may be allowed to build our hopes upon the fruit buds, which are now sufficiently developed to reveal their number, then a very heavy fruit crop is assured. Apples, peaches, plums, cherries, and nuts give especial promise, pears being the only fruit that is lighter than usual in fruit buds. Of course, any or all of these bright prospects may be blighted by the weather. The blizzard experienced through the south on April 5 and 6 would do some damage to apricots and early flowering peaches where not well protected; gooseberries may also have suffered somewhat, but on the other hand it may prove a blessing in disguise in checking the winter moth and other caterpillars, which were already noticeably at work. It would also act as a timely check to a dangerously early spring.

PROTECTION.—Protection will need careful regulation; extra covering that may be put on to protect the blossom from cold cutting winds should be removed at the first appearance of brighter weather, as coddling in any way must be rigorously avoided. Light frost will do very little damage to wall fruit trees if protected with a two feet coping of glass or boards. The coping will, of course, remain a little longer, but opportunity should be taken of removing it as soon as the fruits are set and the weather settled.

STRAWBERRIES.—These should be protected with netting as soon as the first flowers open, as promptness in this little matter will oftentimes save the earliest blossoms from injury by frost. A light framework of posts and string may be erected over the beds, about four feet in height, to allow of easy access and comfort at gathering time. Bird-proof netting drawn tightly over this and pegged down on all sides, with any old netting spread loosely over the top to act as extra protection from frost, will suffice.

PEACHES AND NECTARINES.—These will require attention in the way of disbudding, and the work should be done at regular intervals and by degrees, so as not to check root action more than possible. Well-placed basal shoots should be chosen to keep the trees well furnished, and especially is this necessary in the case of young trees. A look-out must be kept for aphis, and on its first appearance tobacco powder may be used. Avoid the use of strong insecticides until the trees are well under way, as the foliage is so delicate in its young stage. Trees that have suffered from a bad attack of red spider the previous season may be given a dressing of sulphur, either applied through a sulphurator or mixed with water and syringed on as soon as the fruits are set. No harm will accrue if the trees are literally smothered in sulphur at this early stage, and this is the most simple and safe method of keeping peach trees from this dreaded pest.

TOP-DRESSING PEACHES. — Peache may now be top-dressed with leaf-soil or spent hotbed material, which will very much assist the trees, by checking a too rapid evaporation during bright weather. It will also encourage the roots to the surface, whole masses of roots being found quite near the top of the ground, especially if leaf-soil be used.—J. Whittle, Cheveney Gardens.

THE KITCHEN GARDEN.

CUCUMBERS.—If the plants were put out on hotbeds in the forcing house, and subjected to a moist suitable temperature, as recommended in an early calendar, they will now be growing freely and showing a plentiful supply of fruit. For a steady demand that is usual in private establishments it is not wise to crop very heavily, but rather to reserve the strength of the plants by continually reducing the number of fruits down to a fair quantity. Keep the vines trained out thinly so that the leaves can make their growth in full light, and as the days lengthen, with more sunshine, apply a good syringing to the foliage twice a day to keep it clean and vigorous. The roots, too, will be active; and will require frequent top-dressings of good mellow loam; if very heavy it may be well to lighten it a little with grit, but do not add much rotten manure. Give applications of liquid manure when it is seen the plants require it.

SALSIFY AND SCORZONERA.—Where these vegetables are required, and likely to be appreciated, now is a good time to make sowings of seed. They are not so particular to soil as many crops, but will grow on most land that is sweet and has been dug and manured. Draw out the drills at eighteen inches apart, and give the plants a distance in the rows of eight inches by thinning them out early as soon as the best ones can be selected.

CHICORY.—This plant is invaluable to the gardener who has to keep up the supply of a salad the whole year round by serving him with succulent leaves at the times when other important plants are the most scarce or hard to produce. Make a good sowing during the next week or so in size according to the likely demand. Give a distance of eighteen inches in the lines, and thin out the plants rather liberally to ensure strong crowns.

PERENNIAL SPINACH.—On land that is light it is sometimes difficult to keep up a constant supply of spinach during the summer months. Where it is so, to avoid against annoyance by failure, make a sowing of perennial spinach now to form a substitute. It is not necessary to select the best position for this crop as it will thrive quite well in semi-shaded places, and on moderately conditioned land. If allowed to remain long the plant becomes robust, and should be given two feet from row to row, and thinned out accordingly.

BEET.—If early roots are wanted make a sowing on a raised border of the turnip-rooted kind, sufficient to carry a supply till the main sowing is ready for pulling. Work the land over with a fork, and incorporate some wood ashes or soot with the surface soil as the work proceeds. When in a proper condition draw cut the drills about one and a-half inches deep, and about fifteen inches apart, and sow fairly thick. Slugs are often troublesome to this sowing, therefore a sharp look out is advisable as soon as the young plants appear above the ground; then dustings of soot and lime will be necessary.

GENERAL REMARKS.—Proceed as the weather will permit with the planting of main crop potatoes. Have the hillocks for vegetable marrows made ready in time for planting. See that sufficient manure is being turned and rotted in readiness for the quarters that will be cleared later of the kales and late broccoli.—C. FLACK, Cholmondeley Castle Gardens.

ANNUAL LARKSPURS.

The various annual larkspurs furnish a group of most beautiful hardy flowers for the garden in summer, and, as they are easily raised from seed, they commend themselves to everyone on the score of economy also. They are seen to greatest advantage when grown for colour effect in beds or borders, while for providing a supply of cut flowers for indoor decoration they form a most desirable and welcome change.

The cultural requirements of larkspurs are of the simplest character; they are best raised from seed sown in the position where the plants are intended to flower; the seed is sown thinly on ground that has been previously dug and manured, April being a suitable time, and as soon as the seedlings are large enough, they are thinned out singly, allowing 9 to 18 inches between the plants, according to the variety. When the plants attain to some height, supports should be afforded them in the form of stakes, which, however, should be of a light nature, so as to be really inconspicuous when the plants come into flower.

One of the best of the annual larkspurs is the charming blue Butterfly, a variety that attains but a height of 18 inches, and associates admirably with white or cream-coloured dwarf antirrhinums or similar shades of violas. The Dwarf Rocket or hyacinth-flowered larkspurs offer a good range of colour, and are excellent subjects to mass in quantity, the habit is dwarf and exceedingly neat, and when in flower the bed presents a most symmetrical appearance. The forms of Delphinium consolida produce flowers that are stock like in appearance; these are taller in growth and are equally effective when massed in quantity, but should always be allowed plenty of room for lateral development. Among branching forms of larkspur Branching Blue and Empress Carmine are two specially good and useful colour forms that come remarkably true to colour; both are light and graceful in habit, and, under favourable conditions attain a height of 3 to 4 feet; the lateral branches always develop well and furnish unlimited quantities of most useful material for supplying cut flowers for indoor decoration.

Nearly all the types of annual larkspurs may be procured in several distinct shades of colour, so that their value in any colour scheme is at least equal to anything else we have among annuals suitable for summer display.

THOMAS SMITH.

PRELIMINARY ANNOUNCEMENT.

A GREAT SWEET PEA SHOW will be held, under the auspices of the Eastbourne Horticultural Society and the Chairman and Directors of the Devonshire Park Company, in

THE FLORAL HALL, DEVONSHIRE PARK, EASTBOURNE.

On WEDNESDAY and THURSDAY, July 19th and 20th, 1911.

ATTRACTIVE PRIZE LIST.

Special Classes for Ladies and the Trade.

Schedules for particulars of the Show may be obtained from Mr. C. R. AUST, Honorary Secretary, 5, Cornfield Road, Eastbourne.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

A Daffodil Show in Piccadilly.

The cult of the daffodil grows apace. Every year new enthusiasts take up the culture of this delightful spring flower, and, like the auricula and tulip and carnation fanciers of other days, they specialise, leaving the majority of popular and cheap varieties to those who fill big flower beds and produce glowing or gleaming effects in woodland, vale, and garden. Such enthusiasts will have already achieved success in the culture of these everyday varieties, and they pass on now to those of higher price, which are different from the rank and file, and have some merit of special beauty, colour, size, form, or rarity, and presently, if still successful, they pay yet higher prices for new seedlings, commence the work of cross-fertilisation and the raising of seedlings, always hoping to obtain something that will be so great an advance that it will carry the raiser's name down to posterity.

There is no doubt a boom in the new, or comparatively new, daffodils, and the aim of most amateur enthusiasts is to acquire the complete stock of a fine new variety, grow it well, and, as it increases, use it for the exchange or purchase of several other new ones, and so the sporting element comes in to some degree.

But the professional raisers and distributors of daffodils, on the one hand, and the budding or regular enthusiasts on the other, have to be brought together somehow, and the multiplicity of spring shows nowadays greatly tends to that end. The fortnightly exhibitions are, of course, a great opportunity for "narcissists" to foregather, and several notable firms who deal largely in daffodils keep open house during the spring season, but it has been left to the Messrs. Barr and Sons, of Covent Garden, to hold a daffodil exhibition in the heart of the fashionable quarter of the Metropolis, and on the Wednesday and Thursday before Easter they had a very delightful display of the choicest varieties at No. 10, Dover Street, Piccadilly. The exhibition was well attended.

We made a few notes, and among the bold, large-crowned, or magni-coronati set a noticeably fine thing was Conqueror, a grand bicolor trumpet variety, with a superb perianth and a pale yellow trumpet of good form. Admiral Makaroff, a finely formed deep yellow Ajax variety, with a beautifully frilled trumpet, is of a pleasing shade of yellow. Stockwell is a splendid upstanding trumpet variety, with widespread frilled trumpet and a large perianth, all of light golden-yellow shade.

King Alfred was, of course, finely represented, and its exquisitely frilled trumpet and rich golden colour make it a real King among trumpet varieties. Cornopean, a neat bicolor Ajax form, with light yellow trumpet, and Alice Knights, the early white variety, were other beauties, while Atalanta, with a long primrose trumpet and white perianth, and the popular and deeply-hued Buttercup were highly attractive. Mrs. Robert Sydenham, Avalanche, and Lolah are three good white trumpet varieties, the former exceptionally good.

Among incomparabilis forms, or those closely approximating to this section, Pedestal attracted attention by reason of its very substantial creamy perianth and yellow straight cut crown. Great Warley was very much in evidence, and Fleetwing, with its frilled yellow crown, was also a great attraction. Bernardino quite took our fancy; it is an incomparabilis variety, with a shorter crown than most of the section; the white perianth segments are very broad, and the light orange yellow crown is wonderfully frilled and crested.

The exquisite silvery-white Leedsi varieties included the lovely Fairy Queen, which was beautifully shown. Princess Maud was another lovely silvery-white.

Incognita, with its shapely perianth and orange-rimmed crown, and the smaller, fiery-cupped Firebrand, attracted general attention. Mascotte has a very bright orange rim to its flattish yellow cup, while Fiery Cross imitates Firebrand in its brilliance, but has a larger and cream-tinted perianth. Gadfly has pure white, slightly reflexing segments, that suggest poeticus parents, but it has a bright, flat, frilled orange crown. Furnace is very bright, but scarcely so flaming as its name suggests, and Bedouin is not so ragged and wild as is Arab, but has a refined, broad-petalled white perianth, and an orange red-edged cup.

Of the new poeticus varieties we noted Lycidas and Cassandra, while double varieties were represented by the old Capax plenus, Volcano, Cernuus plenus, the gold and white Argent, Campanella plenus, and the handsome primrose-yellow Plenipo.

Irene, Jaune à Merveille, and Ideal represented the increasingly popular and useful poetaz section, while among quite small, but very pretty daffodils, such varieties as Sunset, Queen of Spain, Colleen Bawn, Mrs. Vincent, and Cloth of Gold served to throw the larger flowers into sharp relief without losing any of their own quiet beauty.

Horticultural Club.

On Tuesday, the 11th instant, the usual monthly dinner of this club was held at the Hotel Windsor, Mr. Harry J. Veitch, V.M.H., occupying the chair; and subsequently a very interesting lecture was given by Mr. Wilfred Mark Webb, secretary of the Selborne Society, on "The Bird Sanctuary," which has been established between Ealing and Harrow for the protection of bird life amid the ever-increasing dangers which beset it in the environs of the great city. A large number of lantern slides, mainly executed from photos taken by Mr. Poole, who was also present, were shown to exhibit the success which had attended the devotion of a piece of well-wooded land of about nineteen acres to the purpose indicated, by enclosure and adequate protection by a keeper against the raids of birdcatchers and intrusive bird-nesting boys. Many of the slides depicted nests in situ, sometimes with the clutches of unhatched eggs, and sometimes with the young birds, the various modes of building and choice of materials being thus exemplified, and at the same time the precaution taken by the parents to hide the nests from their natural foes. One series of slides was devoted to the cuckoo, whose larger but otherwise similarly characterised egg was first shown in the unwitting foster parent's nest, the next stage in the history being the young cuckoo monopolising the nest entirely after having thrown its unfortunate foster brothers and sisters ruthlessly over the precipice formed by the nest edge. The growth of the young cuckoo was followed up, and its curiously repellent appearance of snake-like markings of black and white shown, together with a presumed further resemblance to a snake owing to the eye-like marks seen in the interior of the beak when gaping to receive its food, a snake-like hiss accompanying such gaping when an intruder appeared. Owing to the provision of nesting boxes and other attractions, the nightingale, which has been missing from the locality for some years owing to unprotection from vandalistic attacks, had recently re-established itself as an annual visitor, and in all a very respectable list of resident or migrant species attested to the value of the sanctuary as a centre. A number of the concluding slides were devoted to the various kinds of nesting boxes and other contrivances to the same end, which had been designed and made on the spot as substitutes for those of German make which had hitherto been largely imported, but were now being supplanted by the simpler and better ones made by those concerned with the sanctuary, and which experience had shown were better fitted for our native birds by their variety dictated by personal study and experience of the birds' particular habits.

A particularly interesting discussion followed the lecture, in which Messrs. Pearson, Cranfield, Bilney, Bunyard, Boyd-Watt, and Poole participated, each of whom contributed his own personal experience in ornithological study as a practical expert. During the discussion both sides of the question were aired, viz., those of birds as foes and as friends. Against two birds an unanimous verdict of "guilty" and sentence of death was pronounced, viz., the carrion crow as a deadly enemy of all other birds, and the common sparrow as both a horticultural and agricultural pest. Kestrels and owls, which, in many parts, are victims of misplaced hostility, were, on the other hand, beneficial, and should be spared, their prey being voles, mice, and other inimical vermin. The bullfinch, starling, and a few others were terribly detrimental to fruit, and where fruit culture was desired, the first-named specially had to be kept under as far as possible. In this connection the lecturer's remarks received a humorous set-back by those of Mr. Bunyard, whose fruit was decimated sometimes by birds which he assumed were probably cherished and incited to propagate in some "confounded neighbouring sanctuary," a remark which was received as hilariously by the lecturer himself as it was obviously intended to be by the speaker.

One result of the discussion was the conviction that "circumstances altered cases," that birds, like all other forms of organic life, were factors in the balance of nature, and that whether they were friends or foes depended largely upon whether, owing to this balance being artificially upset by abundance of food or extirpation of natural foes, or other causes, they became too numerous or otherwise. Over-abundance leading to change of habit in detrimental directions, while a short supply may, and doubtless often does, lead to invasions of insect pests which it was the province under ordinary conditions of the birds to keep under.

A hearty vote of thanks to the lecturer concluded the meeting.

Dundee Horticultural Association.

The usual ordinary monthly meeting was held in the Technical College on the evening of the 14th inst. The President, Mr. Wm. Christison, presided, and the subject of "Pear Culture" was admirably treated upon by Mr. William Ritchie, Telford House Gardens, Stirlingshire. After briefly referring to historical records regarding the introduction and evolution of the pear, the lecturer referred to some of the ancient trees to be found in Scottish orchards, particularly those at Lindores Abbey and at Telford Orchard, near Blairgowrie. In the last-named place there were three huge trees over 300 years old, one of which had a girth one foot from ground, of 13½ feet; at 3 feet from the ground, girth 9½ feet; here it breaks away into huge branches, each as large as a good pear tree, and these have a diametrical spread of 15 yards. Considering the age and size and consequent exposure of such trees, they are in a prolific fruit-bearing condition, and still making good healthy growth. With such an object-lesson in front of him one could not wonder at the enthusiasm and practical knowledge displayed by the lecturer as he entered into the cultural details of pruning, training, budding, grafting, etc. Exhibiting a photograph of a good tree grafted by himself on a whitethorn stock many years ago, he remarked upon the dwarfing influence of the latter on the growth, and its fruit producing tendencies; as a stock he thought it eminently suitable for bush and pyramid form.

His remarks on pruning and training of wall trees were greatly enhanced by his reference to diagrams and sketches which he had prepared, illustrating his methods, and the practical results obtained as shown by the branches and twigs laden with bursting flower buds were convincing proof of his sound knowledge.

Strongly condemning hard, close winter pruning, Mr. Ritchie advised August pinching and a system of pruning in winter, whereby the leading shoots were merely shortened one-third of their length; this resulted in fruit buds being formed along the entire shoot the following year.

After Messrs. Benvie, Campbell, Slater, Grant, and others had eulogised the lecture and the lecturer had replied to one or two questions raised, he was accorded a hearty vote of thanks on the motion of Mr. James Bethel.

Mr. William Benvie, Inchmartin Gardens, Carse-of-Gowrie, exhibited several dishes of apples, and the following varieties were noted in the pink of condition: Baumann's Red Reinette, Warner's King, and Bramley's Seedling. Votes of thanks to exhibitor and chairman terminated an enjoyable and profitable evening.

East Anglian Horticultural Club.

"The Care and Management of the Lawn." This was the subject of an essay competition open to the members of this club at the April meeting. Five papers were received, and the writers did themselves and the subject great credit. Generally speaking, the lawn does not come in for that amount of thought and care which it requires, and the soil needs some artificial or other manure to replace the food constituents extracted by the grass roots. The subject of worms—Are they good or harmful?—entered largely into an animated discussion which followed. The balance of opinion being in favour of them, as they are so useful in drainage.

The exhibition portion of the meeting was a striking feature. Messrs. Daniels Bros., Lim., Norwich, displayed an array of roses, acers, and forced flowering shrubs; Mr. F. Williams, gardener to Louis Tillett, Esq., Catton, Norwich, staged some fine fruits of a new strawberry raised by Mr. Robt. Holmes, Tuckswood, Norwich, named "Tuckswood Early." It is a medium size, elongated fruit, of beautiful colour, and excellent flavour, and crops profusely when forced. Mr. W. Shoesmith, gardener to F. W. Harmer, Esq., Cringleford, staged a very nice plant of cymbidium, and a lady's spray composed of dendrobiums by the same exhibitor, was exquisite. Mr. Frank Neave, Lingwood, displayed some gorgeous zonal pelargonium blooms with large, massive pips and trusses.

British Gardeners' Association.

LONDON BRANCH.

The monthly meeting of the London branch of the British Gardeners' Association was held at Carr's Restaurant on Thursday, April 13. There was a good attendance, and a very interesting debate upon the policy of the B.G.A. was opened with an able address by Mr. Smith, of Kew Gardens. Many interesting points were raised, and Mr. Smith was strongly supported by a number of young gardeners from Kew. An increase of 2s. 6d. in the annual subscription, so that a fund might be started for the relief of unemployment, was very strongly advocated. It was also thought that the time had arrived for the appointment of a paid secretary who could devote the whole of his time to the interests of the association. Mr. Hawes, in moving a vote of thanks to Mr. Smith, expressed the hope that some of the suggestions made would be adopted. The debate had been a most instructive one, and he hoped that good results would accrue.

Huntingdon Daffodil Show.

The daffodil exhibitions held in the Corn Exchange, Huntingdon, are delightful functions, and they attract the good folks of the town and district in large numbers. The competition is open entirely and wholly to amateurs, and there is a very great keenness to secure the awards for the sake of the honour and glory of a win over one's neighbours and friends. The life and soul of the Huntingdonshire Daffodil Society is Miss Louise L. Linton, the hon. sec., who is admirably supported by an energetic committee, and by five members of her own family at Buckden, and Colonel and Mrs. Linton of St. Ives.

The Corn Exchange is not an ideal place for an exhibition, as all the light comes from one side, and there is barely enough room for exhibits and visitors. The show held on Wednesday, April 19, was a fine one, the competition keen, and the flowers, on the whole, of good quality and rich colouring. Curiously enough such varieties as Emperor, Empress, and King Alfred were a trifle small all through, but Lucifer, Firebrand, Lulworth, Cresset, Circlet, Sir Watkin, and the newer Poet's varieties were particularly good.

In the premier class thirty distinct varieties of daffodils are required, not fewer than three and not more than nine flowers of a variety, and the three great divisions of daffodils to be represented. Here the chief prize was a silver vase presented by Messrs. Barr and Sons, Covent Garden, and it was won by Mr. F. Staffurth, Frieston Priory, Lincoln, who set his flowers up finely, and had beautiful examples of Cresset, Chough, Glory of Leiden, Firebrand, Lucifer, Citron, Sceptre, Kings Norton, Princess Mary, Circlet, and Southern Star. Mr. J. Cator, M.P., Woodbastwick, Norfolk, who won first place last year, was second on this occasion, and some of his best vases were of Mdme. Plemp, Sunrise, and Gloria Mundi; Miss Linton, Stirtloe House, Buckden, third. There were six competitors.

There was a very poor competition in the classes for daffodils grown in moss fibre, and second prizes only were awarded in each case. There were eight entries of three varieties of Poeticus daffodils, and here Mrs. Nowell-Usticke, Philleigh, Cornwall, annexed the premier award, and with charming blooms of Cassandra, Poet Laureate, and Epic; Mrs. Stables, Offord Hill, Godmanchester, second; and Miss Olive Linton, Buckden, third.

Mr. H. R. Darlington, Potter's Bar, who is as keen on daffodils as on roses, secured the leading award for six trumpet varieties, not more than five blooms of each, with splendid examples of Seraphim, Glory of Leiden, Fairy, Victoria, Golden Bell, and Outpost. Mrs. Lisborough second; and Mr. T. Longland, Warboys, Huntingdon, third.

Miss Irene Linton scored for six medium-crowned varieties with Princess Mary, Katherine Spurrell, Lucifer, Fairy Queen, Seagull, and Leonie; Mrs. Stables second, and Mr. H. R. Darlington third. For six small-crowned varieties Mr. Jas. Marshall, Hartford Cottage, Huntingdon, secured the chief award with high-class blooms of Virgil, Epic, Dante, Homer, and Horace; Miss Olive Linton second and Lady Lilford, Lilford Hall, Oundle, third. Lady Lilford was also successful for three varieties of polyanthus narcissi, and was followed in order by Mrs Carnegy, Alconbury, Huntingdon, and Mr. H. R. Darlington. Miss L. L. Linton led for three poetaz varieties with handsome vases of Triumph, Aspasia, and Klondyke; Mrs

Daily Mail

£1000

Sweet Pea Prize

THE DAILY MAIL will hold a Sweet Pea Show on July 28th and 29th at the Crystal Palace (Festival of Empire). The following prizes will be given for the best bunch of Sweet Peas consisting of 12 spikes containing three varieties at least.

FIRST PRIZE £1,000, SECOND PRIZE £100, THIRD PRIZE £50, and 1,000 MEDALS.

SPECIAL Children's Prizes amounting to £50.

Premiums for the best bunch of artificial Sweet Peas, entirely made in England, will also be given.

No Competitor may enter more than one bunch.

The varieties need not be named.

The bunches may be sent by post and will be arranged for the Competitors.

Entries cannot be made till a date in June, when a succession of announcements will be made in the DAILY MAIL.

The Competition is designed to spread the cultivation of Sweet Peas among Amateur Gardeners.

The following, as announced in the DAILY MAIL, are ineligible :—

Those who have at any time grown flowers for profit.

Those who have at any time won a first prize at the National Show.

Those people who employ more than one paid worker, gardener, or other, in the garden.

The gardeners or persons so employed by such persons as are disqualified in the preceding clause.

Members of any Institution, Agricultural or other, who grow their flowers in a common garden.

The families or dependants of any of the categories enumerated above.

Full details of the Competition, with instructions in the culture and management of the flowers, will appear from time to time in the "Daily Mail" until the date of the Show.

R. L. Towgood, Farm Hall, Godmanchester, second, and Miss Irene Linton third.

The best single flower of a trumpet daffodil was a very clean Weardale Perfection from Mr. Staffurth; Mr. Darlington second with Duke of Bedford, and Lady Lilford third with King Alfred. Mr. Staffurth was also first for one medium-crowned daffodil with a fine flower of Bernadino; Miss Joan Linton second with Lady Mary Boscawen, and Mr. Darlington third with Lucifer. For one small-crowned variety Mr. J. Linton came to the front with a very big clean specimen of Virgil; Miss Linton followed with Circlet, and Lady Lilford with Armorel. The three best vases of Leedsi varieties were from Miss Linton, Mrs. Longland coming second, and Mr. J. Marshall third; all showed White Lady in fine form. Miss Irene Linton's first prize set of three varieties of double daffodils consisted of Argent, Plenipo, and Dubloon, all good; Mr. Darlington second, and Mrs. Towgood third.

Mrs. Stables scored for four varieties of daffodils, any sections, three blooms of each, with Lucifer (very fine), Sir Watkin, Firebrand, and Mdme. de Graaff; Rev. O. P. Fisher, Graveley, Huntingdon, second, and Miss Irene Linton third.

In the county class for six varieties of daffodils, any kinds, three to five flowers of each, there were nine contestants, and here Mrs. Senior, Brampton Park, Huntingdon, scored with splendid blooms of Mdme. Plemp, Mdme. de Graaff, J. B. M. Camm, Glory of Leiden, Emperor, and Empress; Mrs. Towgood second, and Mrs. Carnegy third. In the other county class, for three varieties of daffodils, any section, Mrs. Towgood secured first prize with Stella Superba, Vanilla (sweetly-scented), and Sir Watkin; Mrs. Senior a close second, and Mrs. Longland third.

In the numerous classes for spring flowers, such subjects as hyacinths, tulips, primroses, flowering shrubs, perpetual carnations, etc., were freely exhibited and well staged. The leading prize-winners in this section were Lady Lilford, Mrs. J. Linton, Colonel Chichester, Godmanchester; Mrs. Senior, Mr. J. Cator, and Mr. Hunnybun.

Non-competitive exhibits ranged round the Exchange included daffodils, tulips, and double primroses from Messrs. R. H. Bath, Lim., Wisbech; choice new daffodils from Messrs. Cartwright and Goodwin, Kidderminster; spring flowers and roses, from Messrs. W. and J. Brown, Peterborough; Tritonia crocata Alberta and greenhouse plants, from Mr. J. E. Perkins, Huntingdon; seedling and other new daffodils of great variety and merit, from Messrs. Barr and Sons, Covent Garden; orchids from Mr. G. W. Miller, Wisbech; interesting hardy flowers from Mr. G. Reuthe, Keston, Kent; and very fine perpetual carnations from Messrs. Laxton Brothers, Bedford.

FORTHCOMING ENGAGEMENTS.

TUESDAY, April 25.—Royal Horticultural Society: Daffodil Committee meets at 11.30; Fruit, Floral, and Orchid Committees at 12 o'clock; lecture at 3 p.m. on "The Tulip—Its Problems and History," by Rev. J. Jacob; Scientific Committee at 4 o'clock.

National Auricula and Primula Society's Show, in conjunction with Royal Horticultural Society.

National Rose Society: Special General Meeting, 3 p.m. Rose Conference with address by Rev. J. H. Pemberton, 5 p.m., Dinner 7 p.m., at Westminster Palace Hotel, Victoria Street, S.W.

WEDNESDAY, April 26.—Hereford Daffodil Show.

Royal Horticultural Society's Examination of School Teachers.

Irish Gardeners' Association.

THURSDAY, April 27.—Midland Daffodil Show at Birmingham; two days.

LONDON POTATO MARKETS.

Prices rule high, and appear likely to remain so.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

SEEDS FROM THE CANARY ISLANDS. H. W. J., Liverpool: Rhodocistus Berthelotianus is more correctly Cistus vaginatus, and though sometimes listed as Cistus candidissimus, this last is at most but a varietal form of C. vaginatus. It is a shrub that would scarcely be hardy in your district; about two feet or a yard high, it flowers in May and June, and the blooms are rose-coloured; sow in sandy soil in a greenhouse. Convolvulus floridus, from Teneriffe, is an evergreen greenhouse plant of trailing habit, and produces its pink flowers in late summer and early autumn; sow in gentle heat. Delphinium staphisagria, a native of Southern Europe, is a biennial that should be sown in a cold frame; some of the plants may be put out in the autumn, but most of them should be kept in the frame until spring, and be then put out where they are to flower. It grows from two feet to three feet high, and its short-spurred blue and white flowers are carried in loose racemes in May and early June. Spartocytisus rubegenus is none other than our old friend Cytisus fragrans, the popular yellow-flowered and fragrant greenhouse shrub so largely grown for market, with which, no doubt, you are perfectly familiar. Spergula rubra we do not know, but the several kinds of spurrey are annuals, hardy or half-hardy, so you might treat it as such. Echium strictus is an evergreen greenhouse plant that produces erect spikes of blue flowers in summer; sow in sandy soil in the greenhouse. Kleinia neriifolia is a native of the Canary Islands, and is a succulent plant belonging to the natural order Compositæ; the yellow flowers are produced in the autumn. Sow the seeds in sandy soil, just covering them, and place in gentle heat to germinate.

BROWNED EDGES TO RICHARDIA LEAVES.—E. P., Bristol: The browning of the edges of the richardia leaves may be due to one of two causes, or both. Under bright sunshine, if allowed to become dry at the roots, the plants flag, and if this error of management is repeated the edges of the leaves turn brown. Another possible cause is the exposure of the foliage to cold draughts. At this season of the year there is especial need for great care in ventilation, as bright sunshine is often accompanied by extremely cold winds, and the latter, acting upon the tender leaves through the ventilators, will do considerable damage in a short time.

PLANTING WATER-LILIES.—W. B., Sudbury: In our issue of March 25 we gave considerable information concerning hardy water-lilies and how to plant them, and also included an article on "Waterside Plants." You can obtain a copy of the issue, post free, for 2½d. from the Publisher, Gardeners' Magazine, 148-149, Aldersgate Street, E.C. Water-lilies may be planted any time from the end of April to the beginning of July.

DAMAGE TO CARNATIONS.—E. G., Hounslow: The damage done to the plants is due entirely to the birds, probably sparrows. These pests—they are little less in most places—tear out the growing points of the carnations, probably because these are succulent morsels, though often they seem to do damage in a spirit of wicked mischievousness. Use black thread or netting to keep the birds away.

WEEVILS IN BROAD BEAN SEEDS.—J. M., Yorks: The bean seeds are very badly infested with the Bean Beetle (Bruchus granarius), and one of the seed-sent had as many as five of the tiny beetles in it. As the young seedlings depend in large measure upon the amount of food material stored up in the seed substance, it follows that if the seeds are badly "holed" by beetles the crop is not likely to be a great success. The eggs of the Bean Beetle are laid in the opening bean flower, and as these hatch out they eat their way into the seed vessel, and bore into the growing seed. The seed develops and closes up the tiny hole through which the grub entered, but the latter gradually eats out a little chamber for itself, turns to chrysalis form, and presently becomes a tiny beetle. In the spring the beetles break through the seed skin, and are then ready to increase their kind. If infested seeds are sown, the prospect of a recurring attack is very great, as the beetles emerge from the seeds and remain in the soil until favourable conditions induce them to come up through the earth. Seeds so badly infested as those of which you have sent us a sample should be returned to the seedsman with a request that they be replaced by sound ones.

WOUNDS ON APPLE TWIGS.—R. F. M., Devon: We are endeavouring to find the cause of the trouble, and will report later.

NAMES OF PLANTS.

M. B., Lincoln.—Adiantum cuneatum grandiceps.

W. B., Sudbury.—1, see next issue; 2, Daphne Laureola.

C. L. G., Wareham.—1, Ribes sanguinea; 2, Prunus sinensis; 3, Eleagnus pungens.

S. C., Lee.—1, Forsythia suspensa; 2, Anemone blanda; 3, Soldanella alpina; 4, Erythronium dens canis; 5, Primula rosea.

R. E. C., Bridgwater.—1, Magnolia stellata; 2, Primula viscosa; 3, Erica carnea; 4, Ribes aurea.

J. J. M., Bedford.—1, Hymenophyllum radicans; 2, Kerria japonica; 3, Odontoglossum excellens; 4, O. Wilckeanum.

OBITUARY.

Mr. J. MELVILLE.

We regret to learn that Mr. J. Melville, for many years superintendent of Finsbury Park, under the London County Council, died suddenly on Sunday evening last. Mr. Melville was a very capable gardener and organiser.

MR. WILLIAM E. GUMBLETON.

The death of Mr. W. E. Gumbleton, on April 4, at Belgrove, Queenstown, removes from horticultural and botanical circles one of the most interesting personages. At Belgrove he had an exceptionally fine collection of rare plants, and it was his great delight to be the first to cultivate newly introduced species and varieties. He was a great patron of horticulture, and his wide knowledge of plants rendered him famous throughout the United Kingdom and on the Continent. He was a frequent visitor to and correspondent of Kew, and he rarely missed a Temple Show. Mr. Gumbleton, whose portrait we gave in our issue of July 20, 1907, was seventy-one years of age.

MR. R. N. G. BAKER.

The rose world is the loser by the recent death of Mr. R. N. G. Baker, of Exeter, who was for a considerable period a prominent member of the National Rose Society, and took a keen interest in all horticultural movements in Devonshire. He was a frequent and successful exhibitor of roses, and his flowers won many victories, both at the N.R.S. exhibitions and in the West of England.

MONS. C. du BOIS LARBALESTIER.

M. Larbalestier, who died recently in Jersey, was an eminent botanist, but he came little before the public, as he devoted his attention chiefly to lichens, of which he was the chief British authority. His splendid collection of lichens was secured some time ago by Mr. W. Cadbury for the Birmingham University.

MARKETS.

◆

COVENT GARDEN.

Flowers.

Trade is rather good for so soon after the holidays; daffodils and tulips sell freely and liliums are good.

"CARRUSTICIDE."

The Best and Cheapest Remedy for Carnation Rust and other Fungoid Diseases.

A well-known Carnation Grower writes:
Dear Sir, The Nurseries, March, Cambs.
"During the 27 years I have been growing Carnations (Perpetual and American) I have tried most of the fungicides placed on the market, but yours is the best. It is a pleasure to see how "Carrusticide" catches hold of the Rust and destroys it. I should say your preparation will be extensively used when it is better known." Yours very truly,
GEO. CLARKE.

One gallon makes 25 gallons for spraying purposes—Price 3s. per quart, 7s. 6d. per gallon. Special quotations for larger quantities.
Terms: Cash with order.

SUTTON'S PRIZEWINNER RUNNER BEAN. The finest exhibition variety, of superb table quality.
Per pint, 2s.; quart, 3s. 6d.

Mr. John Hudson, Westleigh, writes:—"At Shrewsbury, Leicester, and Leamington, I have this year (1910) won prizes value £30 1s. 6d. for Vegetables, the produce of your seeds. I have tried nearly all other varieties of Runner Bean, but your Prizewinner is ahead of all others for quantity and quality. For exhibition during the last three or four years I have grown no other."

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

KELWAY'S LATEST SUCCESS.
GRAND PRIX AND GOLD MEDAL, Japan-British Exhibition, White City. Unanimous award of the International Jury to Kelway and Son for Pæonies, Delphiniums, Gladioli, Pyrethrums, etc.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

THE LIBERTY of the KELWAY GARDEN versus the Tyranny of the Bedding-out system. Infinite variety: no sameness of treatment.

ABSOLUTE FREEDOM of choice of treatment for your garden or garden borders. See "Gardens of Delight," post free, 6d.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

KELWAY'S MANUAL OF HORTICULTURE is the best of all Garden Books. 2s. post free, from KELWAY and SON, LANGPORT, SOMERSET.

TESTIMONIAL.
From ——, Esq., Guildford.

"I may say that your Illustrated Catalogue is without doubt the finest book of the sort I have had the pleasure of seeing."

NOW IS THE TIME TO PLANT KELWAY DELPHINIUMS which have been improved almost out of recognition in the past twenty years. They produce plants ranging in height from four to eight feet, exceptionally hardy and with a rich profusion of choice blooms in all the shades of that valuable colour, blue.

Choice named varieties: 24s., 34s., and 56s. a dozen. Carriage and package free for remittance with order.

The celebrated present-day Delphiniums, and nearly all the best well-known varieties shown at exhibitions, originated in Kelway's Langport Nurseries.

TESTIMONIAL.
From Mrs. ——, Eltham, Kent, 18th April, 1911.

"The Delphiniums and Pyrethrums you sent me three years ago are doing splendidly, and were a joy last summer.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

POULTRY AND KENNEL APPLIANCES of every description. Write for latest Catalogue, free on application.—BOULTON and PAUL, Lim., Norwich.

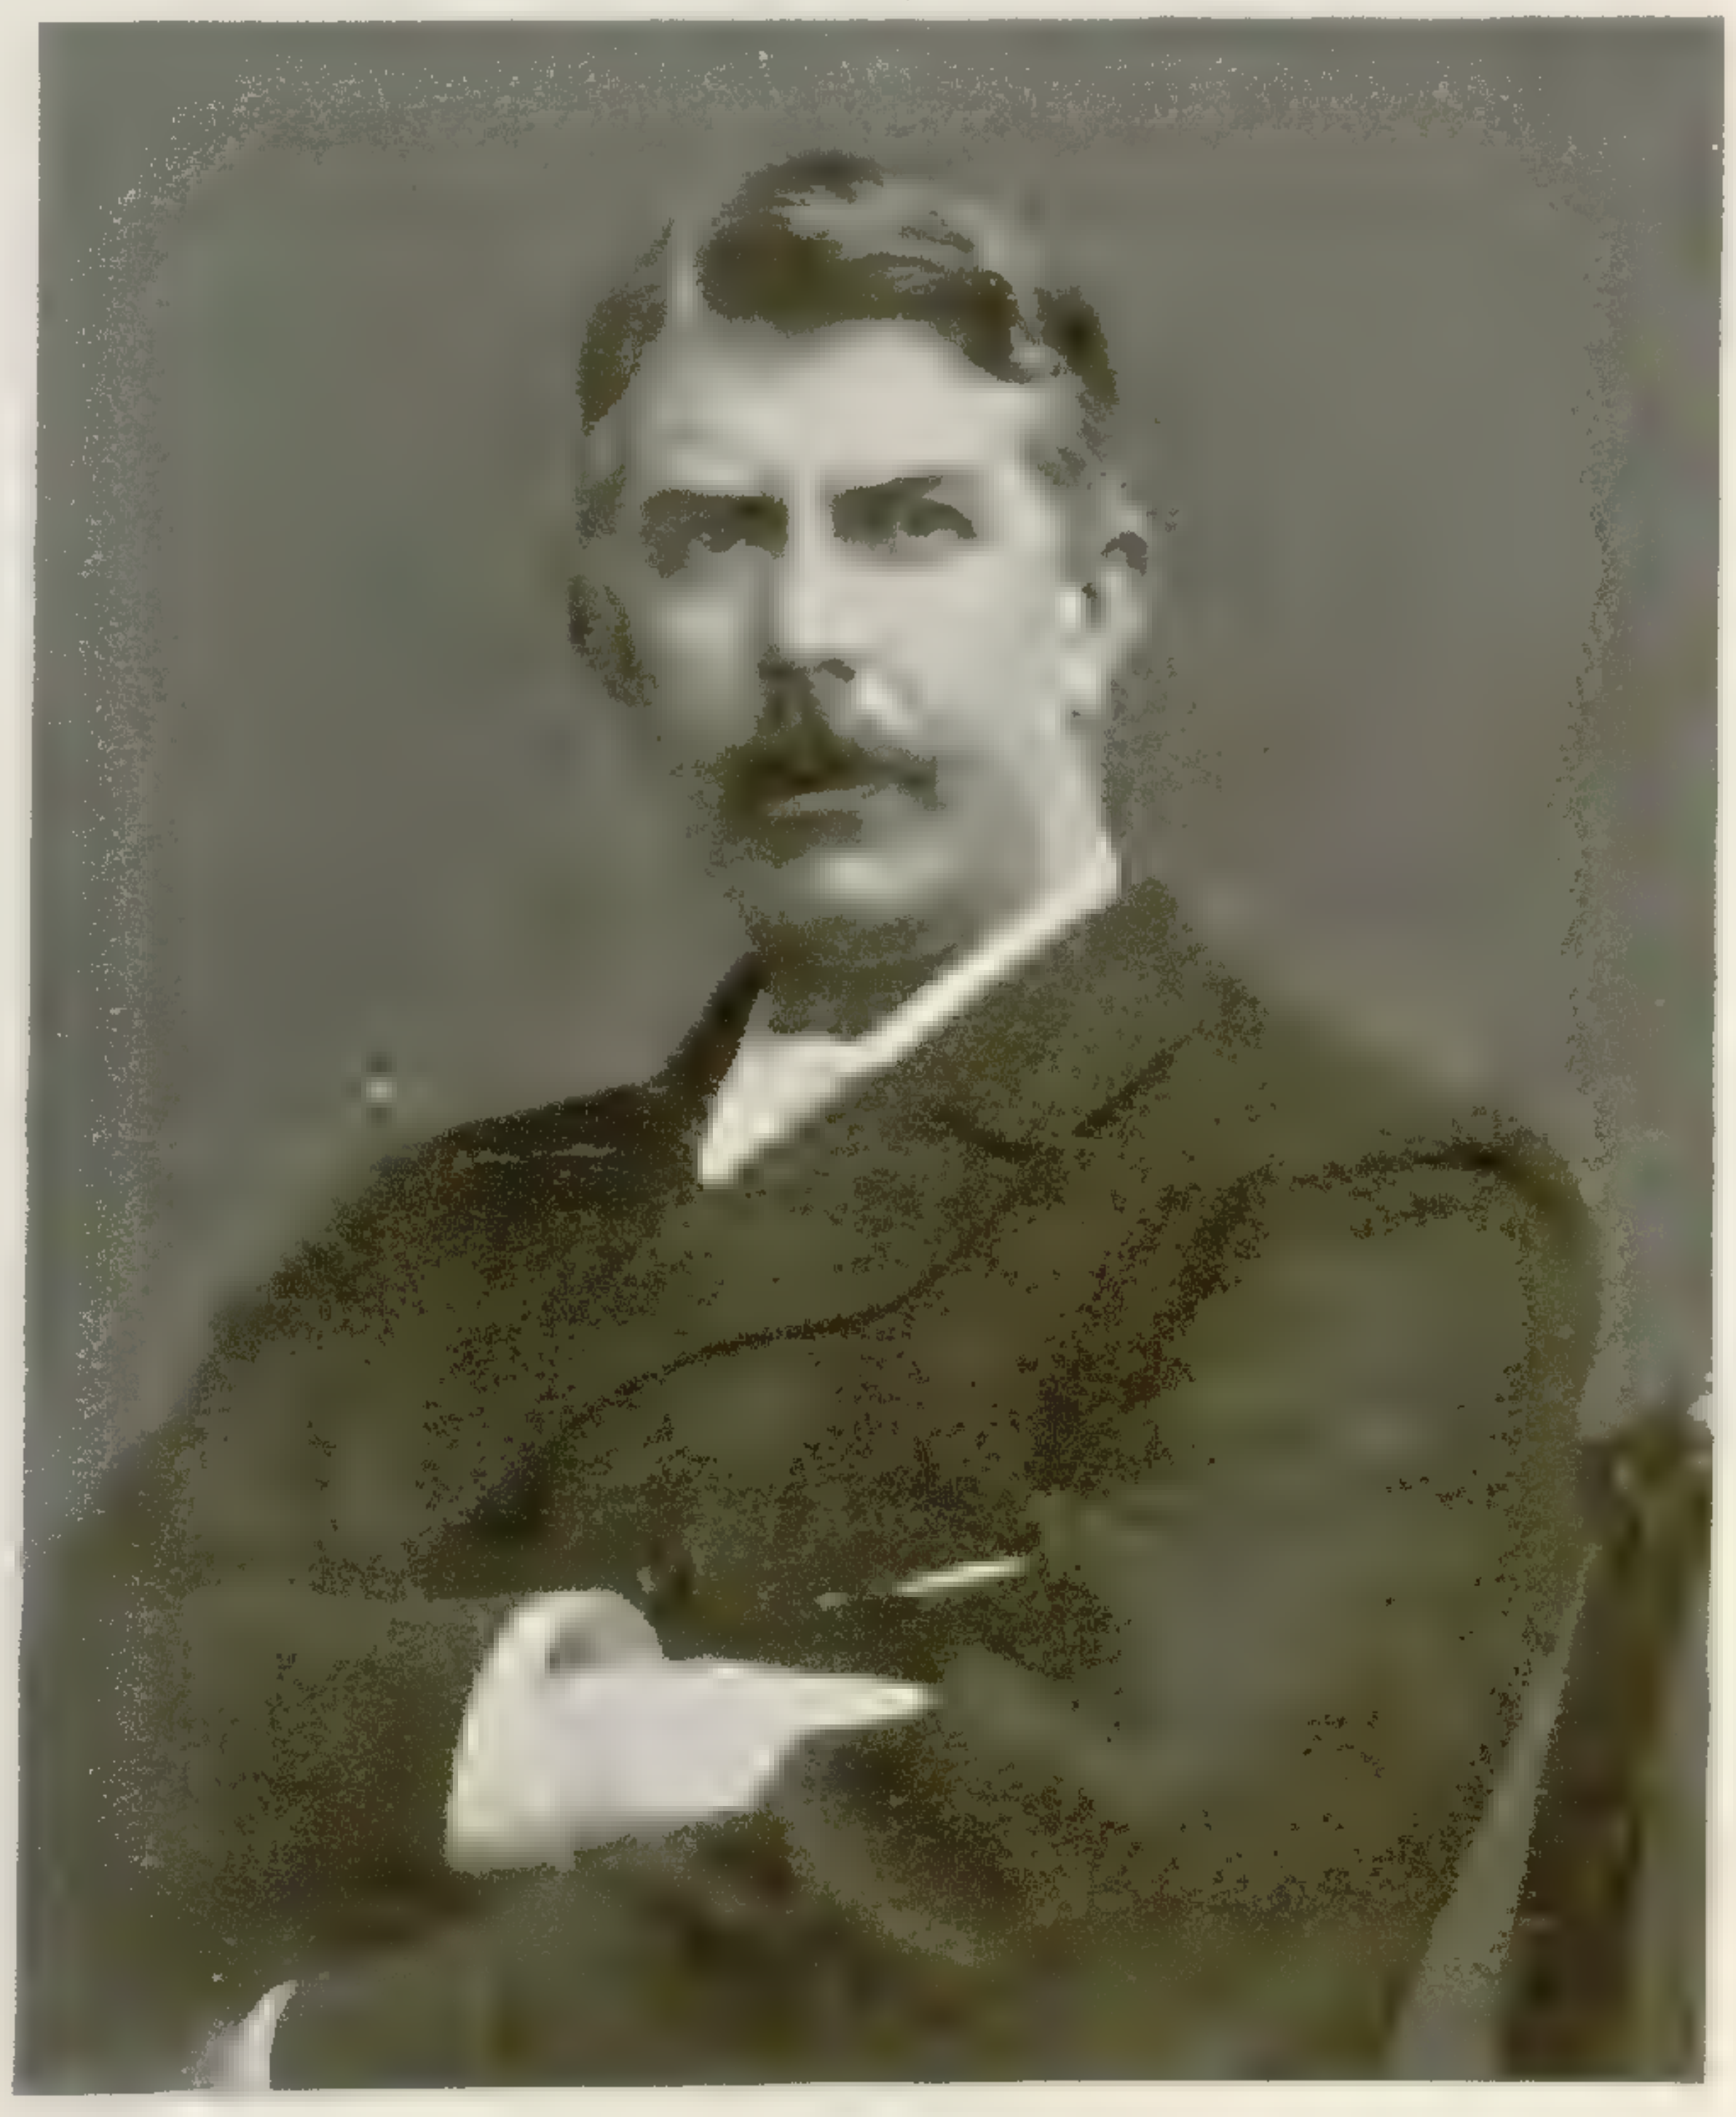
THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Evergreen Trees and Shrubs.

Fully appreciating the usefulness of trees and shrubs with persistent leafage as aids in enhancing the interest and attractions of all classes of gardens, we have considered it advisable in the interest of our readers to devote considerable space in the present issue to some of the more important kinds. We have selected the present date for calling prominent attention to evergreens for two reasons. One is the hope that as we have just entered on the season in which many of them can be planted with the assurance of successful results, we may be able to render our readers assistance of great practical value. The other is a desire to interest them in this section of ornamental trees and shrubs, and thereby induce them to study the various kinds during the next six months, when outdoor study can be carried on under the most pleasant conditions. If this important group of ligneous and arborescent vegetation is studied systematically, and with some degree of persistence, it will soon be recognised that it contains a much greater diversity in form and colour than is commonly supposed to be the case, and that a thorough acquaintance with the most distinct and beautiful kinds should be regarded as an essential part of the education of those who are concerned with garden management. Much improvement in this direction has been made within recent years, but something more has to be accomplished before we can hope to see an adequate representation of the finer kinds in the majority of gardens, and some reduction in the number of aucubas and common laurels which have for so long a period enjoyed a high degree of popularity. Happily, there has of late years been a considerable reduction in the numbers annually planted of the two last-named classes, excepting, it may be, in gardens planted by builders who are anxious to give the environment of the houses they have erected a furnished appearance at the smallest possible cost. We have no wish to exalt the evergreens at the expense of the trees and shrubs of deciduous habit, and, so far from doing this, we would direct special attention to the necessity for maintaining a proper balance between the two classes. Trees and shrubs that wholly shed their leaves annually are, generally speaking, much lighter, and more elegant in appearance than are the evergreens, and their leaves undergo several changes in the process of growth and decay. First, there is the tender green of the young leaves, which constitutes so great a charm of the landscape in spring; this passes into the sombre green of the fully developed leaves in the summer; and this, when the breath of autumn has passed over the land, is replaced with soft browns, or, it may be, colouring of the most resplendent character. Having completed their allotted functions the leaves return to Mother Earth and leave the trees and shrubs bare. It is then that the value of evergreens as aids in the adornment of the garden is brought into special prominence. There will, however, be no difficulty in recognising their utility at all seasons of the year, provided the selection has been judiciously made. Handsome objects in themselves, they present a striking contrast to the deciduous kinds, and serve to accentuate the charms of their distinctive characteristics. An essential point is to avoid planting too liberally such kinds as, like the evergreen oaks, have very dark foliage, especially in gardens of comparatively small size. There is no occasion for planting dark-hued subjects other than in small proportions, for there is a wide range of subjects from which to select. Hollies should, as a matter of course, be well represented, and although the leaves of some of the finest forms are of a dark green hue, their glossy surface lights them up in a marked manner, except, it may be, on a very dull winter's day. There are, of course, a considerable number of hollies with silvery and golden variegation, and these should be planted freely, for the colouring, while in some cases decidedly rich, is less aggressive than the foliage of some other shrubs, and is in no way trying to the eyes in the brightest of summer weather. There are many other variegated evergreens of much beauty, as will be seen on reference to the article devoted to them which appears on another page. All that are enumerated are fully deserving of attention, and we would strongly recommend the more general planting of the fine golden form of Elæagnus pungens, of which an illustration is given in association with the article referred to. Evergreens, as in the case of other plants, differ considerably in hardiness, and the kinds that are considered rather tender should not be planted largely until it has been found by practical test, or from observations made in other gardens in the district, that they may be planted with the assurance of successful results. The reputed tender shrubs should not, as is often the case, be left severely alone, because the result of this policy is a reduction in the attractions of the garden. The evergreen magnolia is a case in point. It is very seldom that a plant away from a wall is met with, yet at Kew there is a splendidly developed bush twenty feet or so in height, and what will thrive in the Royal Gardens will succeed over a wide area in England. There is one class of evergreens that should certainly be more largely planted in gardens than has yet been the case, and that is the one formed by the hybrid rhododendrons. If varieties having a good habit are selected their rich green leaves will render them more or less attractive throughout the year, and during their season of flowering will produce colour effects that are quite unequalled by those of any other group of plants that can be grown out of doors in British gardens. Higher praise could not well be given, and those who act upon our advice and devote a larger area to these shrubs will, in a few years hence, have good cause for being satisfied with the results.



MR. WILFRED MARK WEBB, F.L.S.,
Secretary of the Selborne Society.

Mr. Wilfred Mark Webb, F.L.S., whose portrait we have the pleasure of giving in this issue, has from an early period in his life devoted much attention to nature study, and by means of his activities in various directions, and the books he has written on the subject has rendered splendid service in promoting the study of natural history on scientific lines. Mr. Webb, who is the editor of "Knowledge" and "The Country Home," spent many years in teaching botany and horticulture, and from 1893 to 1898 was the senior assistant lecturer on biology for the Essex County Council, and later he was seven or eight years lecturer on biology and nature study for the Surrey County Council, and in both of these positions did excellent work. Appreciating the needs of students Mr. Webb has written a book on "The Principles of Horticulture," which, at the time of its publication, we had the pleasure of reviewing in these pages. From the first he has taken an active part in promoting the nature study movement, and as one result of the remarkable ability shown in connection therewith he was some years since elected to the important position of honorary secretary of the Selborne Society, which has accomplished such excellent work in connection with natural history; and he is also chairman of the Brent Valley Bird Sanctuary Committee. In connection with the second of the two offices Mr. Webb gave a lecture on the Brent Valley Bird Sanctuary at the recent meeting of the Horticultural Club, and this, as our report will have shown, was highly appreciated by the members. It is interesting in this brief note on Mr. Webb's work in connection with the promotion of the study of natural history, to recall the fact that he was secretary of the first Nature Study Exhibition, and of the first Country in Town Exhibition, and to mention that he is a member of the Rural Education Committee of the County Councils Association, and of the Organising Committee of Section D (Zoology) of the British Association. Among the books written by Mr. Webb, in addition to the one already mentioned, is a monograph of "The British Woodlice" and the "Eton Nature Study," and "Eton Nature Study Note Book."

The Horticultural Charities.—We wish to draw the attention of our readers to the annual festival meeting of both the Royal Gardeners' Orphan Fund and the Gardeners' Royal Benevolent Institution, which are to be held in the month of May. These functions are somewhat earlier than usual, owing to the forthcoming Coronation festivities, and we would urge that the claims of these two most deserving horticultural charities be well considered in a year like the present, when money will be freely spent, and the needs of the orphans and the helpless aged members of our craft may possibly be overlooked. Mr. N. N. Sherwood, V.M.H., a most generous supporter of all good works, will be the genial president of the Orphan Fund Dinner, which is to be held at 7 o'clock on Thursday, May 4, at the Hotel Cecil, Strand, W.C. Sir Marcus Samuel, Bart., so well known in financial and horticultural circles, will take the chair at the dinner of the Gardeners' Royal Benevolent Institution, to be held in the beautiful and famous Grocers' Hall, in the City of London, at 7 o'clock, on Tuesday, May 23, the evening of the first day of the Temple Show.

Spring Flowers at Belvoir Castle.—The high reputation which the gardens of Belvoir Castle have so long enjoyed for the extent and beauty of the displays of spring flowers is fully maintained this season. It would probably be more exact to say that it has been enhanced by the wealth of flowers that now form a series of effects of surpassing beauty. The plants of all kinds have come remarkably well through the winter, and they are now at their best; should the weather be favourable they will remain in good condition for several weeks hence. The Duchess's garden is open to the public every week day, and the large number of visitors during the past fortnight show that the generosity of the Duke of Rutland is fully appreciated. Mr. W. H. Divers, the chief of the Belvoir Castle gardens, may be heartily congratulated on the success he has achieved in the production of this season's display of spring flowers.

The Late Monsieur B. Latour-Marliac.—Mr. James Hudson, V.M.H., whose interest in water lilies is so well-known, writes with reference to the late M. B. Latour-Marliac: "The death of this distinguished hybridist, whose name will always be associated with the genus Nymphæa, took place a few weeks back, at his home at Temple-sur-Lot, in the province of Lot-et-Garonne, in the South of France. It was in the raising of the many beautiful hybrids of the water lily, that now grace many a lake and pond in this and other countries, that M. Marliac's name came prominently before the horticultural public some 15 years or so back. Our lamented friend had worked with a definite purpose in view, and though often discouraged, yet he persevered until he saw the reward of his many years of patient work. After working for ten years he saw some signs of improvement in colour, but his hopes were dashed to the ground by the loss of this seedling. Still he went on until he secured the now well-known hybrids that were first distributed by him. Since that time many more have been raised and put into commerce by his indefatigable labours. In recognition of his work with the nymphæa the Veitch Memorial medal was awarded to him in 1898, but as far back as 1889 he received the 'Premier Prix à l'Exposition Universelle de France.' He left many fine forms behind him that have not yet found their way into commerce; these seedlings will in due time be placed upon the market. The business will now be conducted by his son. His widow survives him, Madame Latour-Marliac having been, and still is, a keen enthusiast in the work. Monsieur B. Latour-Marliac was elected Mayor of Temple-sur-Lot in 1893. He died at the ripe age of 80 years, but his name will live so long as the lovely water lilies that he raised are to be found in cultivation. M. Latour--Marliac was, I would add, an old subscriber to the Gardeners' Magazine."

St. George's Day (April 23) was observed in London and in many of the provincial towns, and roses, which are now abundant in the markets and at the florists' were worn by large numbers of persons. At Windsor, the Queen was presented, on behalf of the Royal Society of St. George, with a basket of roses. The varieties were the bright red Richmond and the snow white Frau Karl Druschki, and the blooms, of which there were one hundred of each variety, were arranged in a large white enamelled basket, ornamented with white and red ribbons. Upon the red ribbon was inscribed in white, "To England's Queen on England's Day," and on the white ribbon was the inscription, "With the love, homage, and devotion of the members of the Royal Society of St. George and branches." As the roses were presented to "England's Queen on England's Day," the society responsible for the presentation does not appear to have been particularly patriotic in selecting American and German roses for filling the basket, when we have so many beautiful roses available that have been raised in the United Kingdom.

Promotion of Forestry in Scotland.—A committee, composed of Sir John Stirling-Maxwell, Bart. (chairman), the Right Hon. Lord Lovat, C.B., K.C.V.O., the Right Hon. R. C. Munro-Ferguson, M.P., Mr. John D. Sutherland, Sir John Fleming, Sir Matthew Wallace, and Mr. R. H. N. Sellar, with Mr. H. Warre Cornish, Dover House, Whitehall, S.W., as secretary, has been appointed by the Secretary for Scotland "To report as to the selection of a suitable location for a demonstration forest area in Scotland; the uses, present and prospective, to which such area may be put (including the use that may be made of it by the various forestry teaching centres in Scotland); the staff and equipment required for successful working; the probable cost; and the most suitable form of management. To report as to any further steps following upon the acquisition of the said area which, in the opinion of the committee, it is desirable should be taken with the view of promoting sylviculture in Scotland, due regard being had to the interests of other rural industries."

Perpetual-flowering Carnations.—Those who are interested in these beautiful and deservedly popular flowers should make note of the fact that the tenth exhibition of the Perpetual-flowering Carnation Society will be held in the gardens of the Royal Botanic Society on May 2 and 3.

Carbon Bisulphide as a Sterilising Agent.—The result of experiments made in the Jodrell Laboratory, Kew, go to show that the use of carbon bisulphide for the purpose of exterminating eelworms and similar parasitic organisms in the soil and roots of pot plants, is attended with very great risk. The carbon bisulphide was poured on to the crocks through the drainage hole in every case; one dram to a forty-eight sized pot proved fatal to worm and plant alike; half a dram defoliated the plants but did not kill them outright. The "Kew Bulletin" points out it would not be wise to attempt the treatment of pot plants in vigorous growth with carbon bisulphide with the object of eradicating eelworm, etc. Fridericia bisetosa, the Oligochaet worm that suggested the experiment, is snow-white, as slender as thread, equal in thickness throughout, and about three-quarters of an inch in length. It occurs in old horse-dung, among rotten leaves, etc., and probably from such sources finds it way into the soil used by gardeners. The treatment of such leaf-soil, etc., with carbon bisulphide some time before it is used would be a wise precaution. The same remark applies to the soil introduced into tomato houses, etc. In dealing with carbon bisulphide it is very important to remember that it is highly inflammable, the heat from a lighted cigarette being sufficient to cause an explosion.

Clandon Park, Guildford.—In our next issue (May 6) we shall give an illustrated account of the beautiful gardens of Clandon Park, near Guildford, the Surrey seat of the Earl of Onslow. These gardens are especially remarkable for the success that has been achieved in the use of hardy flowers.

Fall of a Large Elm Tree at Hampton Court.—One day last week a large elm tree fell with little warning in the wilderness at Hampton Court, and severely injured a Dutch lady and gentleman, and also slightly injured other members of their party. Mr. W. J. Marlow, the superintendent of the Palace Gardens, happened to be near at hand, and rendered assistance to the injured visitors, who were, after treatment at Molesey Cottage Hospital, conveyed to Kingston Infirmary. This is further evidence of the need for great care in the management of old elms, especially where these are in public parks and gardens.

Horticultural Exhibition at Weymouth.—A horticultural exhibition is to be added to the attractions of the Royal Counties Agricultural Society's Show at Weymouth in June next. The dates are June 13, 14, 15, and 16. Mr. C. S. Fuidge, whose wide experience makes him eminently suitable for the position, has been appointed superintendent of this horticultural section, and from him all particulars may be obtained. His address is 7, Silverdale Road, Southampton.

Additions to the Kew Library in 1910.—The books, periodicals, and manuscripts added to the library of the Royal Gardens, Kew, during 1910, are very numerous, and the list, in the form of an appendix to the "Kew Bulletin," occupies fifty-two octavo pages. The list is printed on one side of the page only to allow of its being cut up and used by those who make the Kew catalogue a basis of their own. A considerable number of the additions have been made by gift, and these include material collected for a projected second edition of Lowe's "Yew Trees of Great Britain and Ireland," consisting of printed matter, manuscript, and photographs, all presented by Mr. J. Lowe's executors.

Eradication of Bracken.—Within the past twenty years or so the Common Bracken (Pteris aquilina) has spread with great rapidity in some parts of Scotland, and has been especially aggressive on some of the richer pastures in the Western Highlands. As the bracken is of little food value, and effectually checks the growth of nutritious herbage, the spread of the plant has given rise to considerable anxiety on the part of land owners, and the question has been much discussed at the meetings of the various agricultural societies with but little result. Lieut.-Colonel Fergusson-Buchanan has devoted considerable attention to the question, and by adopting a very simple method of procedure, such as we have frequently recommended in the case of other weeds, has succeeded in clearing a large area of the fern on his Auchentorlie estate, Bowling, Dumbartonshire. He has succeeded in checking the spread of the bracken, and by the end of the year he will, it is anticipated, have exterminated it from six hundred acres of moor and low ground. This extermination has been accomplished by the systematic cutting of the fronds. The effect of cutting the fronds was first noticed seventeen years ago, when the bracken was cleared behind the shooting butts. It was observed that the growth became less vigorous each year, and that grass began to grow among the weakened bracken. The lesson of this cutting back was extended, and the undertaking of dealing with the whole 600 acres entered upon. Operations were begun on the outside of the area in order to prevent the fern spreading, and, working gradually towards the centre, five years' efforts have all but completed the task. Lieut.-Colonel Fergusson-Buchanan states that the acreage cleared of bracken is between 500 and 600 acres, and as the cost has been about £350 he considers that the expenditure, representing at 5 per cent. only £18 per annum, is a small price to pay for the large area of fine pasturage already established. Clean cutting with a scythe or hook has been the most effective, and care is taken to cut below the lowest pinnæ, which, if left, will go on producing spores. Cutting should begin early in the year, and the more the growth of the plant is stimulated by the process the quicker will be its ultimate exhaustion.

ROYAL HORTICULTURAL SOCIETY.

The hall in Vincent Square was again well filled with interesting and effective exhibits. Orchids were scarcely in such force as usual, but daffodils, hardy flowers, forced shrubs, and greenhouse plants were present in abundance. The old order of arrangement of tabling was returned to.

FLORAL COMMITTEE.

Early spring flowers from Messrs. Barr and Sons, Covent Garden, included pretty varieties of Iris pumila, Gentiana verna, tulips, saxifragas, Anemone blanda, Erica mediterranea, Iris tingitana, muscaris, Aubrietias Peter Barr, Royal Purple, H. Marshall, and Dr. Mules, Viola gracilis, and some Ghent and Mollis azaleas.

Mr. Clarence Elliott, Six Hills, Stevenage, had in his little rock garden display some very pretty colonies of Saxifraga muscoides, double primroses, Gentiana acaulis, Androsace sempervivoides, Morisia hypogæa, Primula frondosa, and Aubrietia Fire King.

Messrs. Phillips and Taylor, Bracknell, Berks, showed a beautiful lot of Primula rosea, finely flowered, and of rich colouring; with these were alpine auriculas of great merit and beauty, some fine aubrietias, notably the variety named A1, and a few daffodils.

A large group of the elegant strain of schizanthuses grown by Messrs. Garaway and Sons, Clifton, Bristol, was set up in the upper annexe. The plants were finely grown, the flowers large and of varied hues, varying from white to intense purple. The plants, one in a pot, were in many cases 3ft. high and nearly as much through.

In the group presented by Mr. Amos Perry, Enfield, the leading features were the double form of Anemone apennina, A. Alleni, Primula rosea, P. denticulata, Iris stylosa, Tulipa Forsteriana, Crown Imperials, and the new red-flowered Jasminum Beesianum.

The alpine auriculas from Mr. Chas. Turner, Slough, included several plants of the handsome and effective Golden Gem, a variety well named. Mr. Turner also showed the white Rhododendron Purity.

Mr. H. Burnett again presented a grand lot of Guernsey-grown carnations, the flowers of Mrs. Tatton, White Enchantress, Marmion, R. F. Felton, Rose Doré, Mrs. C. F. Raphael, and Raphael being particularly fine.

Mr. Maurice Prichard, Christchurch, put up a charming lot of alpine and spring flowers, and he showed Gentiana acaule, Cytisus præcox, Primula Forresti, Saxifraga muscoides, Iris pumila varieties, the pretty Tulipa Clusiana, and an assortment of varieties of Primula Sieboldi.

In the rock garden arranged by Messrs. J. Cheal and Sons, Crawley, the leading features were Gentiana acaule, alpine phloxes, Anemone Robinsoniana, Viola gracilis, and some excellent saxifragas.

A very bold and effective exhibit from Messrs. Wm. Cutbush and Son, Highgate, faced the entrance. It was a rock garden display of large size, surmounted by flowering trees and shrubs, the latter including two very tall and big examples of Magnolia soulangeana, mollis azaleas, and rhododendrons. The alpines were grouped in colonies, and chief among the subjects were Iris susiana, Incarvillea grandiflora, Cypripedium spectabile, Primula rosea, P. denticulata superba with especially rich colouring, Anemone pulsatilla, Mertensia virginica, and Primula Sieboldi. The whole arrangement was excellent, and formed a central feature of the exhibition.

Clivias are not often shown nowadays, but Mr. J. Watts, gardener to H. Little, Esq., Baronshalt, Twickenham, grows them well, and showed a fine batch of plants carrying grand trusses of orange-tinted flowers.

The lovely shades of colour seen in the new hybrid gerberas were well displayed by Mr. H. Ellison, of West Bromwich, who had a fine lot of flowers associated with such new ferns as Nephrolepis lycopodiodes and the useful Cyrtomium falcatum Rochfordi.

Roses were delightfully staged by Messrs. G. Mount and Sons, Canterbury, this firm showing fine flowers of Mrs. W. J. Grant, Joseph Lowe, Liberty, Caroline Testout, Richmond, Lady Hillingdon, and Frau Karl Druschki.

Pelargoniums from Messrs. H. Cannell and Sons, Swanley, were a fine feature, their brilliant colours and large blooms attracting general attention; New York, Dublin, Arabic, Princess Dhuleep Singh (a new salmon), King Victor, Scarlet King (new), and Lady Folkestone were notably fine.

Messrs. Bakers, Wolverhampton, showed little groups of Viola gracilis, Incarvillea grandiflora, Saxifraga Red Admiral, the brilliant S. Mrs. Hudson, Aubrietia J. S. Baker, Aquilegia glandulosa, Primula rosea, and alpine phloxes.

Messrs. Stuart Low and Co., Enfield, had a quite brilliant exhibit of Callistemon salignus, acacias, Coronella glauca, blue hydrangeas, and the fine new Hydrangea Mdme. Mouilliere, an array of gerbera hybrids in many colours, and a goodly selection of perpetual carnations.

Beautiful flowers of hybrid gerberas grown at Clewer Mead, Windsor, were exhibited by Mr. W. Allum, gardener to Mrs. H. Oppenheim.

Mr. W. H. Smith, gardener to W. James, Esq., West Dean Park, Chichester, showed a dozen and a half wonderfully fine plants of schizanthuses, grandly grown and flowered, and marvels of high culture.

Messrs. James Veitch and Sons, Chelsea, contributed alpine auriculas, a beautiful set of cactus-flowered cinerarias, as well as examples of a fine old florists' strain, and the neat-flowered Feltham Beauty in white and pink colouring. The cinerarias were greatly admired, and deservedly so.

Mr. G. Reuthe, Keston, Kent, had, as usual, a number of interesting things on view, and his Rhododendron Thomsoni, R. arboreum Kermesina, R. Falconeri, Magnolia stellata, double primroses, tulips, and anemones were notably good.

The scarlet Salvia Glory of Zurich is grand in a mass, and the exhibit of a hundred and more plants from Mr. L. R. Russell, Richmond, was a great success, the blaze of colour compelling attention.

Muscari Heavenly Blue was superbly shown by Messrs. R. Wallace and Co., Colchester, and this firm had an interesting lot of alpine shrubs, Morisia hypogæa, aubrietias, fritillarias, Tulipa saxatilis, T. ingens, the glowing T. Fosteriana, and the lovely little T. Clusiana.

Messrs. T. S. Ware, Ltd., Feltham, were represented by a rockery exhibit in which Trillium grandiflorum, a fine lot of the best aubrietias, saxifragas in variety, primulas in quantity, iberis, violas, phloxes, and other beautiful things were very prettily disposed.

Messrs. B. R. Cant and Sons, Colchester, were exhibitors of roses, and showed these in pots as well as cut flowers; Sallie, Lady Reay, Lady de Bathe, Claudius, St. Helena, and William Allan Richardson were prominent varieties.

Messrs. G. Jackman and Son, Woking, presented a nice bank of hardy flowers, on which were noted nice pans of Lithospermum Heavenly Blue, Phlox Laphami (Perry's variety), Onosma alba rosea, Ramondia Serbica, primulas in variety, Iris cyanea and I. pumila azureus, some gerbera hybrids, and some fine hybrid aubrietias, with a good variety of saxifragas.

Messrs. Storrie and Storrie, Glencarse, had a splendid display of coloured and ornamental kales, which proved a source of attraction to the visitors. They were certainly most charming in their colouring.

From Mr. Vincent Slade, Staplegrove Nurseries, Taunton, came a nice exhibit of zonal pelargoniums, arranged in bunches with their own foliage. The flowers presented a bright and attractive appearance.

Messrs. W. Paul and Son, Lim., Waltham Cross, made a magnificent display of climbing roses in pots, all being in splendid condition, each plant forming a perfect pillar. The White Fairy was superb; other good varieties were American Pillar, Tausendschon, Kathleen, Wartbery, and the quaint Veilchenblau. Some fine hybrid teas in pots were arranged in front, the most attractive being Portia, Albatross, Alice Cory Wright, and Jessie: a very fine group.

ORCHID COMMITTEE.

From Sir Trevor Lawrence's collection at Dorking, Mr. W. H. White brought up Odontoglossum ramosissimum - Edwardi (A.M.), a graceful and pretty hybrid with pink and purple flowers; and Brasso-lælio-cattleya Triune, with huge rosy-mauve flowers.

Mr. H. Redden, gardener to G. W. Bird, Esq., West Wickham, Kent, showed a small group of odontoglossums and odontiodas, all in quite small pots.

Messrs. J. and A. McBean, Cooksbridge, had some very beautiful white and pale rose coloured forms of Odontoglossum crispum and the finely-spotted O. Fascinator, together with good specimens of Miltonia vexillaria.

Mr. R. G. Thwaites, Streatham, presented Odontoglossum Thompsonianum and O. Clytie, with long spikes of purplish flowers, and a good spike of the pure O. Pescatorei virginale.

Mr. Hale, gardener to S. Larkins, Esq., Haslemere, put up a little group of orchids, in which Phalænopsis Schilleriana, catleyas, and vandas were very fine.

Messrs. Hassall and Co., Southgate, showed Odontioda Bradshawiæ, Dendrobium Brymerianum, the pretty little Oncidium pulchellum, Renanthera Imschootiana, and the old Cypripedium Dominianum.

A very fine specimen of the beautiful Cymbidium eburneum, from Lieut.-Colonel H. P. Greenwood, Whitsbury House, Salisbury, carried several dozen lovely flowers.

Messrs. Stuart Low and Co., Enfield, had in their group of orchids numerous dendrobiums, Renanthera Imschootiana, Odontioda Bradshawiæ, Oncidium macranthum, and other interesting things.

Messrs. Charlesworth and Co., Haywards Heath, presented in their collection of orchids such good things as Cattleya Mendeli Princess Mary, the fine Trichopilia Backhousiana, Odontioda Lambeauiana, Cypripedium caudatum, Brasso-cattleya Queen Alexandra, and the interesting Zygo-colax Charlesworthi.

Mr. E. V. Low, Haywards Heath, showed Cymbidium insigne, Cattleya Schroderæ, Cypripedium Rothschildeanum, the rare Bulbophyllum Sillemianum, and Dendrobium Wardianum album.

Messrs. J. Cypher and Sons, Cheltenham, were large exhibitors of orchids, and they had a fine lot of odontoglossums, Cattleya Mendeli, Lælia purpurata, Masdevallia Chimæra, M. Veitchi, odontiodas, Renanthera Imschootiana, Cymbidium Lowianum, C. L. concolor, and the quaint Cœlogyne pandurata.

Messrs. Sander and Sons, St. Albans, presented a fine lot of Cattleya Schroderæ, sweetly fragrant, with Odontioda Charlesworthi, the curious Lælio-cattleya Cora plumosa, Cypripedium Rothschildeanum, a very fine specimen of Maxillaria Sanderiana, and Brasso-cattleya Langleyensis.

Mr. De Barri-Crawshay, Sevenoaks, brought up the brilliant Odontioda Rosefieldiensis, O. Gattoniensis, and Odontoglossum Dirce.

Mr. Day, gardener to H. S. Goodson, Esq., Fairlawn, Putney, showed Odontoglossum percultum, Goodson's var., almost wholly of a deep reddish-purple colour.

DAFFODIL COMMITTEE.

Messrs. Barr and Sons, Covent Garden, had a splendid exhibit of daffodils just inside the entrance door, and they set up goodly bunches of a large number of beautiful varieties, including a goodly set of new seedlings. The arrangement was good, and the flowers of excellent size and colour. Especially attractive were the following varieties: King Alfred, St. George, Pharaoh, White Standard, Gray, White Lady, G. P. Haydon, Rosalind, Timon, Salmonetta, Sequin, and other lovely things, and the new poeticus variety Socrates (A.M.).

From the Rev. G. P. Haydon, Westbere, Canterbury, came a group of new daffodils, chiefly Ajax varieties, and among the most notable things from this successful raiser were Dutch Hoy, Marx, Sevenoaks, Kuroki, Day, Pearl of Kent, Chart, Buxted, Man, Allen, Minster, Oakapple, and Heliodora, the three latter white or cream trumpet varieties.

Messrs. Wm. Bull and Sons, King's Road, Chelsea, contributed a small group of daffodils, all popular varieties, but the blooms were somewhat crowded in the bunches.

Mr. G. Kelf, gardener to A. W. Merry, Esq., Welwyn, Herts, contributed a charming collection of daffodils, comprising about a hundred varieties, and including good specimens of Emperor, Sir Watkin, Blunderbore, Autocrat, Cormoran, Katherine Spurrell, White Lady, Firefly, Zenith, Rev. C. Digby, Lord Muncaster, Solfaterre, etc.

Some especially glorious flowers came from Messrs. Walter T. Ware, Lim., Inglescombe, Bath, this firm displaying two vases of superb flowers of the poeticus var. Horace, four of the beautiful white variety Miss Willmott (F.C.C.), two of Macebearer, and three of the magnificent Great Warley; this little group was a great attraction all day, the flowers and their fine culture appealing to everyone.

Mr. James Douglas, Great Bookham, presented a beautiful bowl of the fine Lady Margaret Boscawen daffodils, comprising about five dozen flowers; Mr. Douglas also staged eight pots of Narcissus calathinus, all from seed, and representing an enlarged strain of this graceful flower. A Cultural Commendation was granted.

A group of choice daffodils from Mr. Christopher Bourne, Simpson, Bletchley, needed rather more space than they had. There were excellent vases of Whitewell, Earl Grey, Norma, White Queen, Countess Grey, Great Warley, Warleyensis, Mrs. Wolverley, White Lady, Lord Muncaster, Lord Kitchener, Chough, and the brilliant new Queen of Hearts (A.M.), with creamy perianth and deep orange cup. The flowers were all of fine quality.

Mr. F. Lilley, Guernsey, brought over a few daffodils and tulips, and among the latter was a good vase of the handsome Le Réve.

Rev. Canon Fowler, Earley, Reading, entered for the Barr Cup, but, being the only entrant, the cup was not awarded. His best vases were of Cormoran, Lady Margaret Boscawen, King Alfred, and Mdme. de Graaff.

FRUIT AND VEGETABLE COMMITTEE.

Messrs. Sutton and Sons, Reading, contributed excellent examples of Early Paris and Golden Ball lettuces, Snow White broccoli, Tender and True climbing French beans, Winter Beauty tomatoes, The Sutton rhubarb, Ideal peas, mushrooms, Inimitable Forcing carrots, and many other spring vegetables of great excellence.

Magnificent Cyprus oranges, five baskets full of real beauties, were submitted by Messrs. Dianellow and Vergopoulos, of Nicosia, Cyprus.

CERTIFICATES AND AWARDS.

First-Class Certificate.--To Narcissus Miss Willmott, from Messrs. Walter T. Ware, Inglescombe, Bath.

Award of Merit.—To Narcissus Queen of Hearts, from Mr. C. Bourne, Simpson, Bletchley; to Narcissus Socrates, from Messrs. Barr and Sons, Covent Garden; to Odontoglossum ramosissimum-Edwardi, from Sir Trevor Lawrence, Bart., to Diacattleya Sanderæ, from Messrs. Sander and Sons, St. Albans; to Rhododendron Pengaer, from Sir J. T. D. Llewelyn, Bart., Swansea; to Auricula Umpire, from Mr. J. Douglas, Great Bookham; and to Primula obconica Chenies' Excelsior, from Adeline, Duchess of Bedford, Chenies.

MEDALS.

Gold.—To Messrs. W. Cutbush and Son, Highgate, for alpines, flowering shrubs, and carnations.

Silver-Gilt Flora.—To Messrs. G. Mount and Sons, Canterbury, for roses; to Messrs. Barr and Sons, Covent Garden, for daffodils.

Silver-Gilt Banksian.—To Mr. H. Burnett, Guernsey, for carnations; to Mr. C. Bourne, Simpson, for daffodils.

Silver Flora.—To Messrs. B. R. Cant and Sons, Colchester, for roses; to Messrs. Garaway and Sons, Bristol, for schizanthuses; to Messrs. Stuart Low and Co., Enfield, for greenhouse plants; to Messrs. Wm. Paul and Son, Waltham Cross, for roses; to Mr. M. Pricbard, Christchurch, for hardy plants; to Mr. L. R. Russell, Richmond, for salvias and flowering shrubs; to Messrs. Jas. Veitch and Sons, Chelsea, for cinerarias, etc.; to Messrs. Storrie and Storrie, Glencarse, for albino broccoli, etc.; to Messrs. Charlesworth and Co., Haywards Heath, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Messrs. J. Cypher and Sons, Cheltenham, for orchids.

Silver Banksian.—To Mr. G. P. Haydon, Canterbury, for daffodils; to Mr. Kelf, gardener to A. W. Merry, Esq., Welwyn, for daffodils; to Messrs. R. H. Bath, Lim., Wisbech, for daffodils; to Burton Hardy Plant Co., Christchurch, for hardy flowers; to Messrs. H. Cannell and Sons, Swanley, for pelargoniums; to W. James, Esq., West Dean Park, Chichester, for schizanthuses; to Messrs. H. B. May and Sons, Edmonton, for ferns, roses, etc.; to Mr. C. Turner, Slough, for auriculas, etc.; to G. W. Bird, Esq., West Wickham, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to S. Larkin, Esq., Chislehurst, for orchids.

Bronze Flora.—To Messrs. R. and G. Cuthbert, for azaleas; to H. Little, Esq., Twickenham, for clivias; to Mr. G. Prince, Longworth, for roses; and to Mr. G. Reuthe, Keston, for hardy flowers.

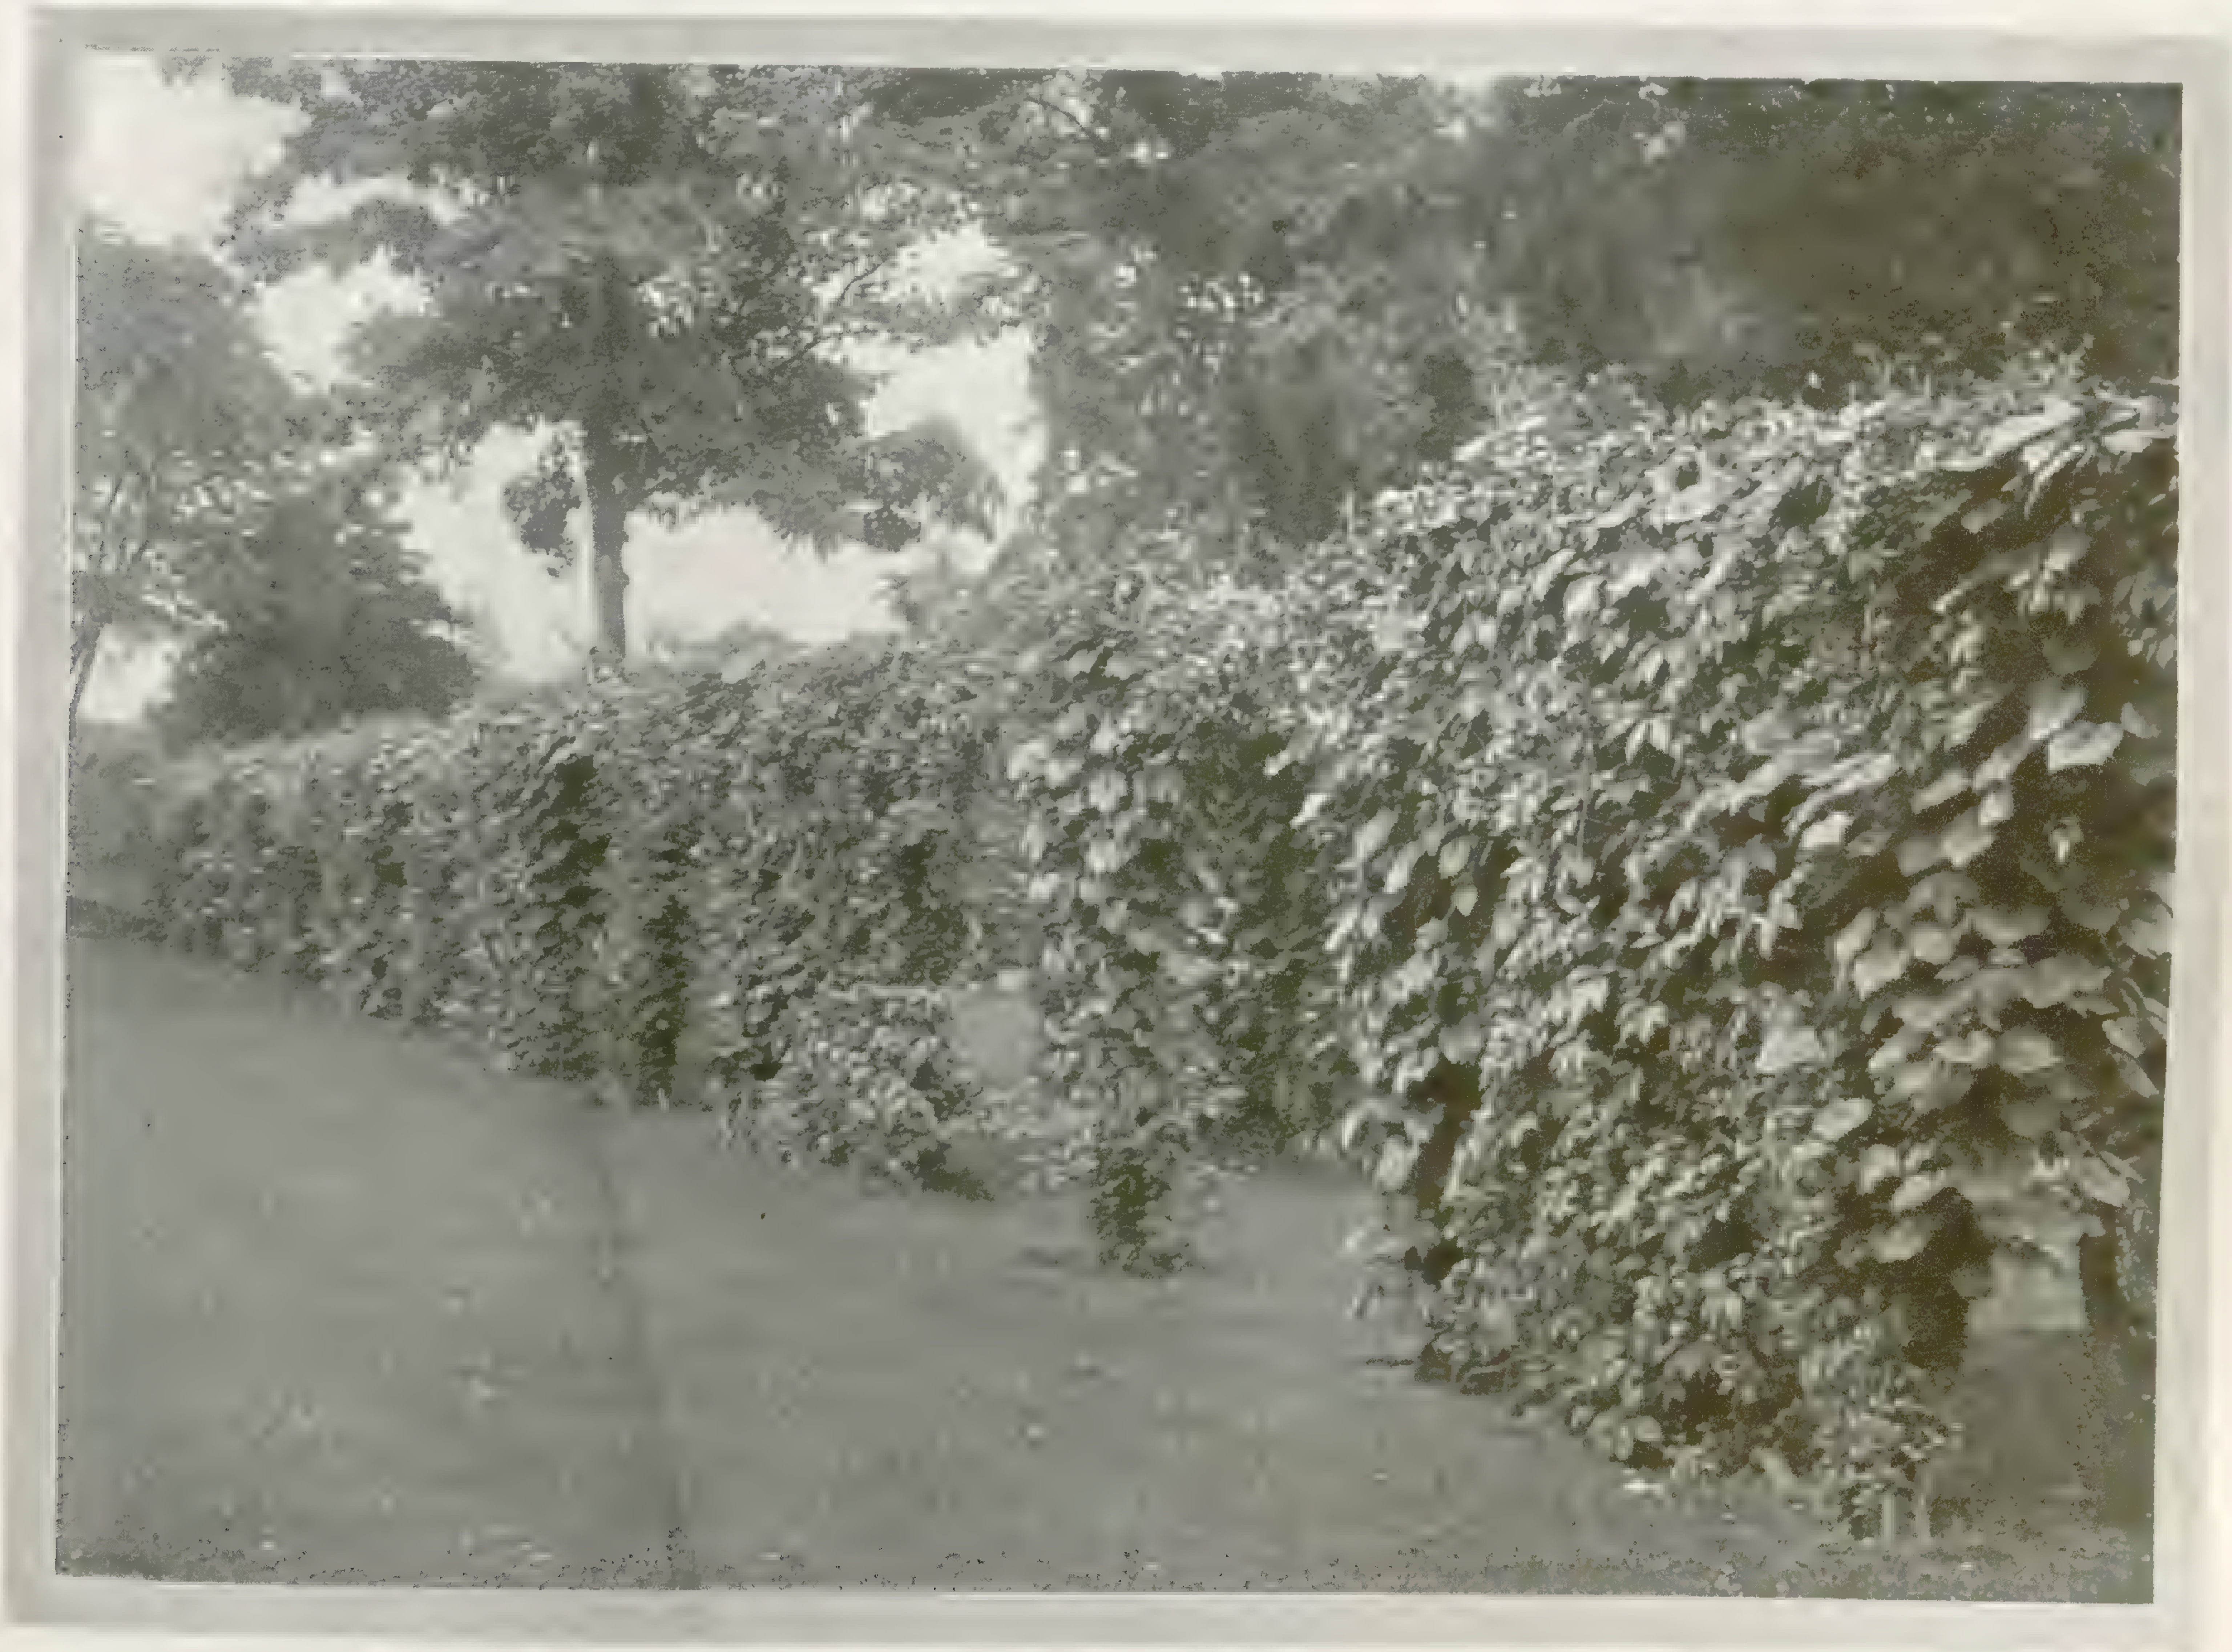
Himalayan Rhododendrons.—The way that these flourish in the extreme South-West of England makes one envious of that especially favoured clime. The advantages enjoyed by dwellers in the West is brought home forcibly every year to residents in less congenial districts, for cut blooms of many kinds, the product of Cornish or Devon gardens, are shown annually at the meetings of the Royal Horticultural Society. A notable feature of these Himalayan rhododendrons is the richness of colouring to be found in the flowers of some of them, notably in one or two varieties of R. arboreum, in R. barbatum, and R. Thomsoni. All have been employed by the hybridist in the production of new varieties. That fine hardy form, Ascot Brilliant, undoubtedly owes a good deal of its richness of colouring to the influence of Rhododendron Thomsoni.—W. T.

Eccremocarpus scaber and aurea.—A plant of inestimable value in the summer garden is the charming Eccremocarpus scaber, a climbing subject with delicate compound fern-like leafage, and clustered tubular flowers of a vivid shade of orange-scarlet. Generally regarded as a perennial, it is, however, quite easy to flower from seeds raised the same season, provided these are sown under glass, and the plants not put out until they attain a fair size. It produces an excellent effect when lightly trained over archways or trelliswork, and may even be allowed to intertwine into a good-sized holly tree with the happiest results. There is also a variety (aurea) with rich golden flowers that, seen under the conditions last-named, are particularly rich and effective. Eccremocarpus succeed in a rich well-drained soil, in a sheltered position open to the sun, and under such conditions it is a true perennial; in a good autumn seed is freely produced, and I have frequently found seedlings spring up in quantity around the parent plant.—Thomas Smith.

PERGOLAS.

The best gardens nowadays consist of a series of gardens within one boundary. Well-planned establishments of the present day have a rose garden, a rock or alpine garden, a water garden, a Japanese garden, a wild garden, an annual garden, the flower garden proper, and I know not how many more individual fancies, but it may be said that no garden is quite complete without a pergola, with its own trim borders.

Although pergolas are most suitable structures on which to train and show to perfection the many beautiful climbing plants we now possess, it may be well to observe that a pergola cannot be set down anywhere; it must have a suitable position, and should serve some definite purpose, otherwise it would only look out of place.



A WELL-FURNISHED PERGOLA IN THE GUNNERSBURY PARK GARDENS.
Showing the use of Ornamental Vines.

Provided a suitable position can be found, the making of a pergola is most simple, and the work may be carried out by any handy man. It may be constructed entirely of wood, or with upright piers of brick or stone erected in pairs, with cross beams of timber of suitable size in proportion to the piers. If in character with the surroundings piers of masonry are to be preferred, as wooden posts will only last a certain time, and after some years decay must be expected.

A pergola should be on the level, and should not curve or twist; it may be of any length, but ought not to be less than eight feet wide or eight feet high. The spaces between the posts or piers along the sides may vary according to the strength of the structure, but should certainly be not less than eight feet. Some of the openings may advantageously be filled in with rustic work, on which the creepers may be spread over. The pathway or walk underneath a pergola may be either of grass or paved with stones, or bricks, or flags, and if preferred a narrow border may be made on either side in which suitable plants may be grown or plunged; some of the liliums are well adapted for this purpose, and right well they look, as also do the German or flag irises; Campanula pyramidalis, and many other partial-shade loving plants will give a very pleasing effect when observed from either end of the pergola. Then again, should the pathway be paved or flagged, many suitable plants can be established between the joints and crevices; for instance, many of the dianthi, sedums, thrifts, linarias, erinus, and a host of other plants, will be quite happy, and look well at any season.

Plants suitable for covering pergolas are abundant, and it is quite an easy matter to make a selection of plants, either for their flowers or foliage, for any particular pergola one may wish to furnish. Laburnums, for instance, may also be planted, and trained to form a growing pergola without the aid of any support, and when established, and in the flowering season the branches are hung with their golden chains of flowers, such a pergola presents a very charming picture. Wistarias may also be employed in the same way, and are excellent either employed by themselves or intermixed with other climbers.

'Wistaria blossoms of purple and white,
In spring-time are truly a beautiful sight;
The vine is ambitious, and spreads far and wide,
But in it is nothing expressive of pride.
Just note how it hangs down its beautiful head
Thus teaching humility's lesson instead''

We have now so many excellent climbing roses that they deserve a special pergola to themselves, where one has the room at command. Other suitable flowering plants are jasmines, polygonums; P. Baldschuanicum, will be found one of the best plants for this purpose. Clematis in variety are all good and useful, perhaps none more so than C. montana, and its more recent introduction C. montana rubens; Forsythia suspensa, Akebia quinata, ceanothus of sorts, and the sweet-scented honeysuckles are all beautiful pergola plants.

In foliage plants we have nothing to surpass the vines, of rampant growth, and with beautiful ornamental leafage that is most conspicuous in autumn, when the brilliant colouring quite lights up the landscape. One of the best is Vitis Coignetæ, a noble vine, with large leaves colouring well in autumn, and of rampant growth. V. Thunbergi is also of vigorous habit, and colours well; V. purpurea, the "Claret Vine," is also useful and distinct, and these, together with some of the more recent introductions from China, such as V. armata, V. megalophylla, V. Henryana, V. Titanea, and V. Thomsoni, will be found unsurpassed where plants for a pergola are required.

The pergola here figured was erected some six or seven years ago, in the lower portion of the grounds of Gunnersbury Park, at the suggestion of Mr. Leopold de Rothschild, and carried into effect by his able head gardener, Mr. G. Reynolds. It is a quite simple structure, built entirely of wood to suit the surroundings; it measures about two hundred feet long, is eight feet high, and eight feet wide, the side openings being about seven feet six inches in width; two side spaces are left open, and then one is panelled in with rustic work. This pergola is flanked on either side by lawns, and the pathway underneath is also of grass; it serves as a connecting link between the gardens of Gunnersbury Park and of Gunnersbury House, though there is now no formal division between the two.

Although this pergola is not entirely devoted to vines, yet from the illustration here given one may learn the usefulness of these ornamental climbers, and their great value, beauty, and noble appearance when employed for covering such structures.

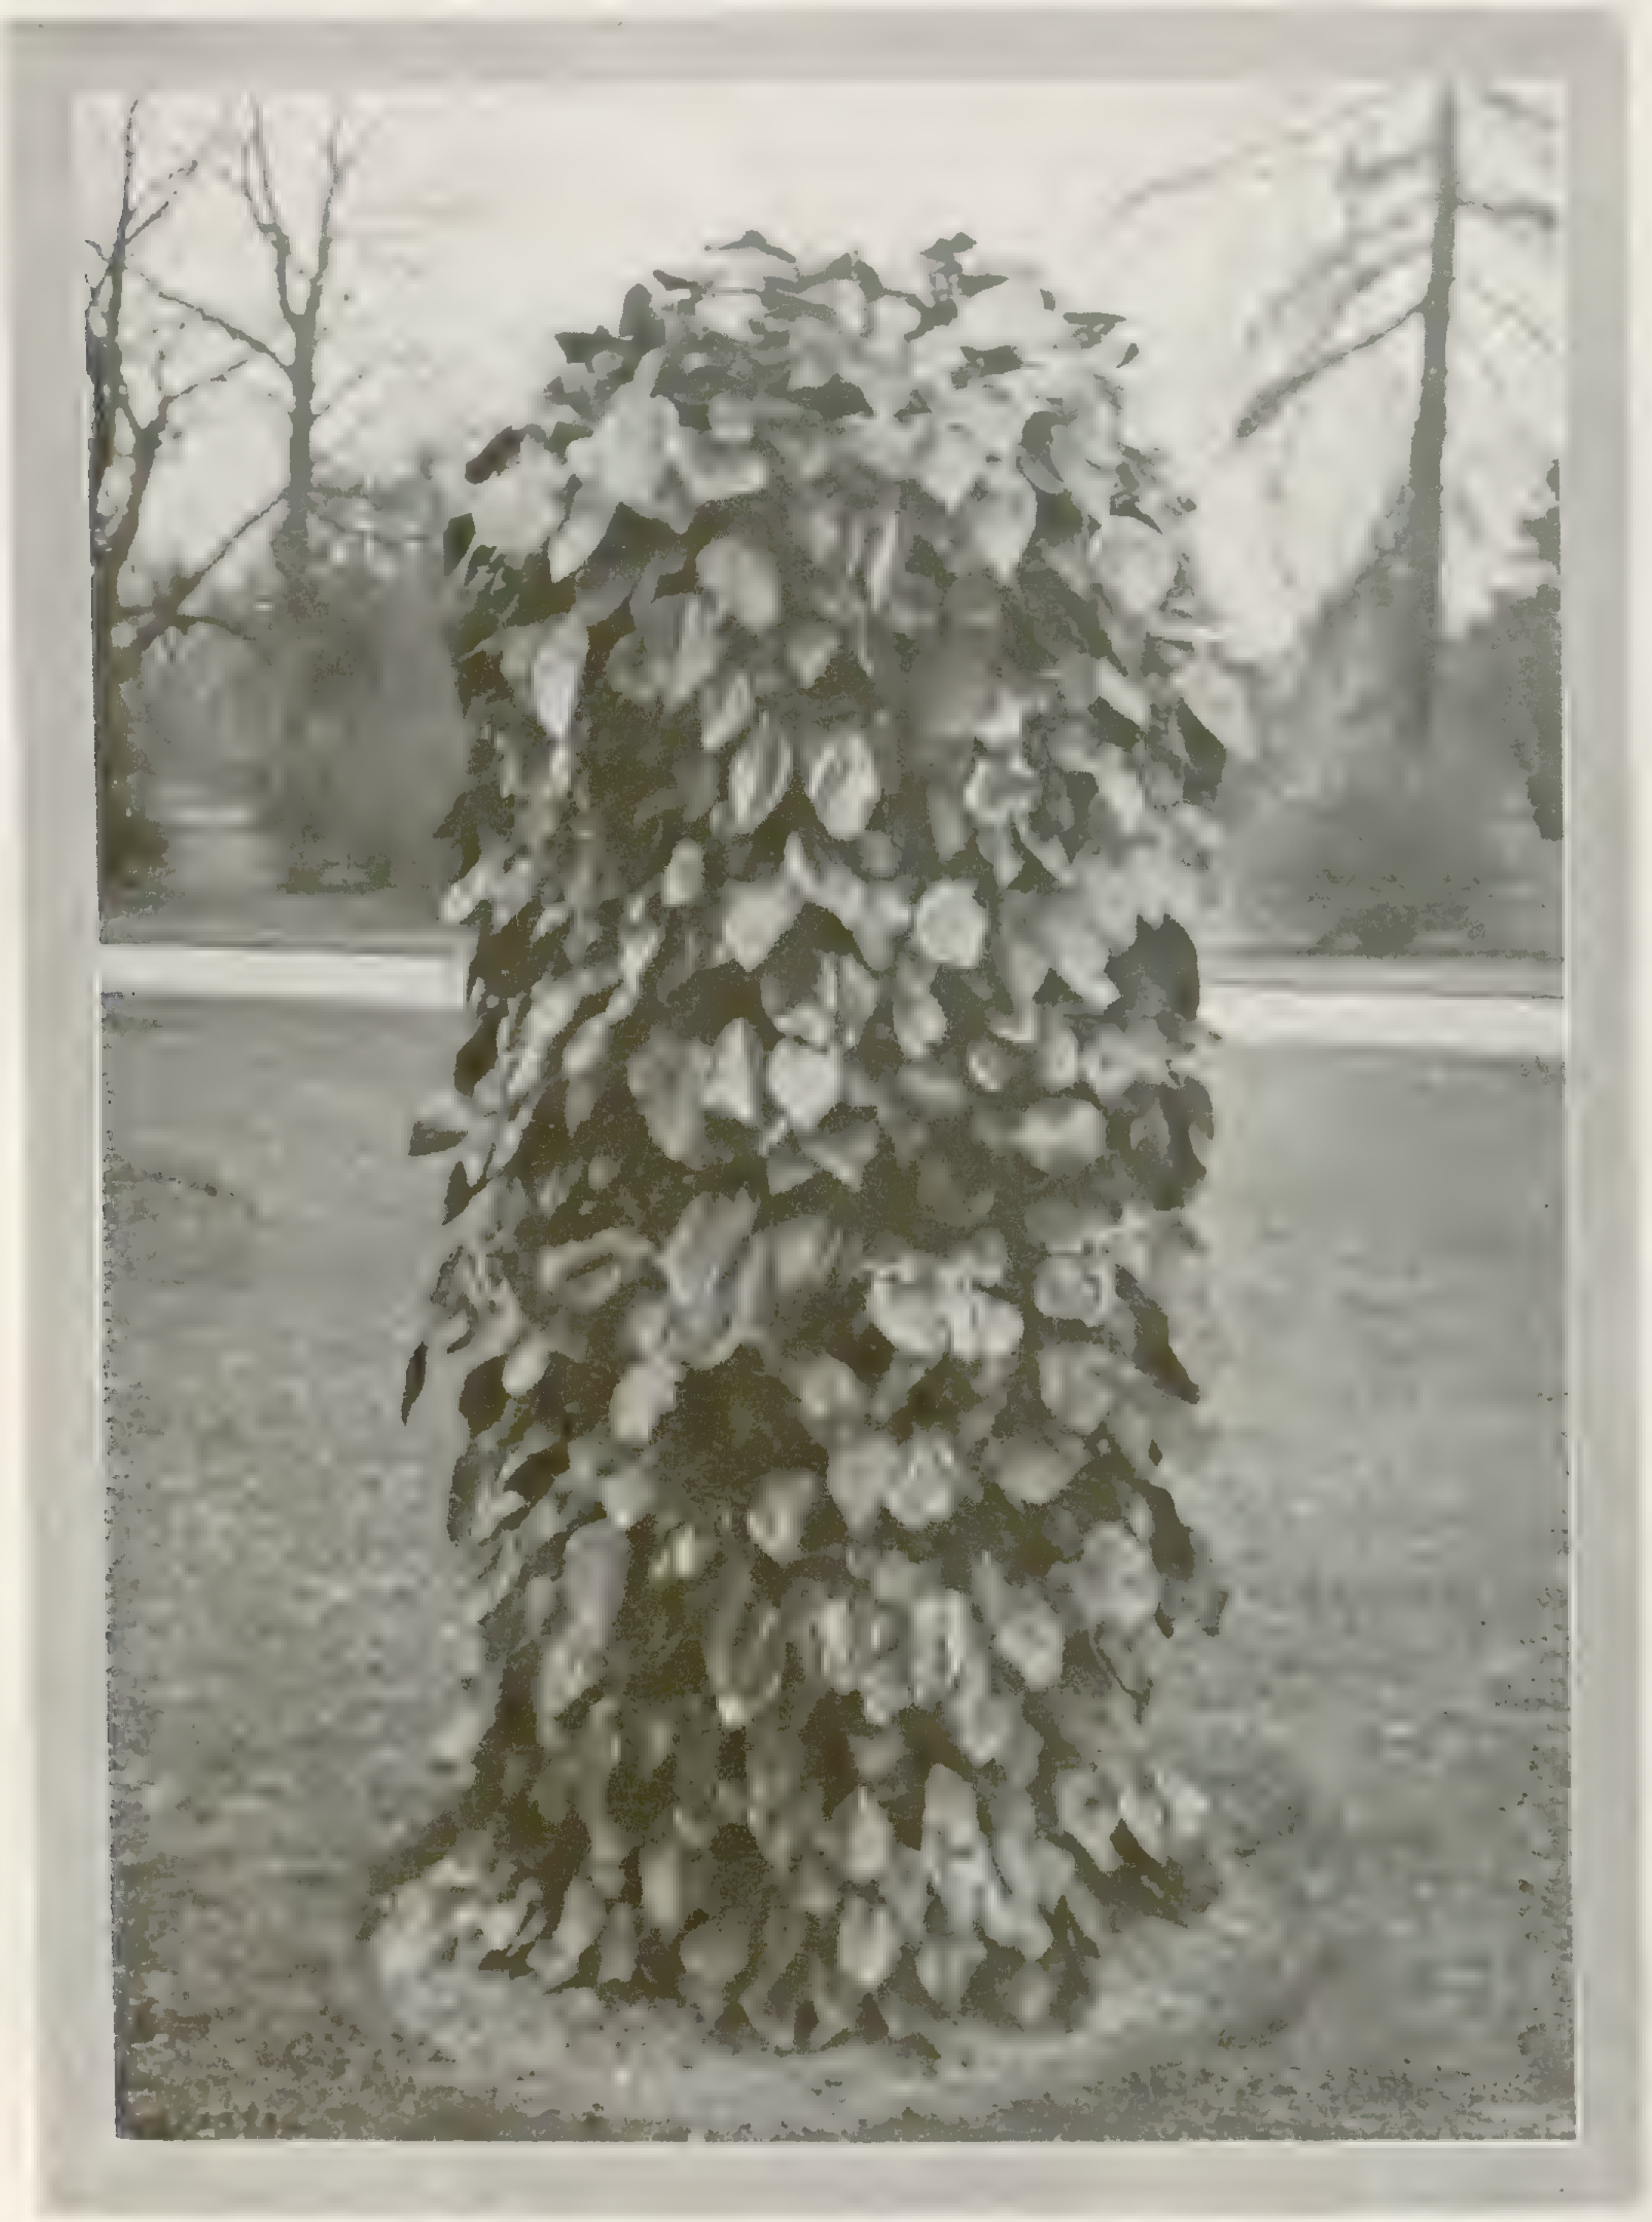
A. Bedford.

THE DOUBLE-FLOWERED PEACHES.

Among April-flowering trees the several forms of the peach are very conspicuous, for their semi-double flowers are extremely showy and varied in character. The normal pink of the typical peach is found in several varieties, and the one called Clara Meyer is perhaps the most beautiful of its colour, for the flowers are large and double. The double crimson variety is, however, more conspicuous, and where one tree only is required, that is by far the most satisfactory one to obtain, for the flowers are peculiarly rich in colour, and are conspicuous from a considerable distance. Another variety with showy crimson flowers is found in dianthiflora. It is distinguished by very large semi-double blossoms, but is hardly so free as the previously mentioned variety. Flore albo pleno adds variety by reason of its double white blooms, while a greater variety of kinds may be obtained by adding Chrysanthemum, camelliæflora, and flore roseo pleno to the list.

Most of these varieties, though the flowers are double or semi-double, produce fruit which, in some instances, is quite good enough for culinary purposes. Stewed or preserved they may be made good use of. In addition to being useful for outdoor effects all these peaches have much to commend them for forcing for greenhouse decoration in spring.

W. D.



THE TOOTHED-LEAVED IVY (HEDERA HELIX DENTATA).
Grown as a pillar specimen.

The Grevilleas.—The grevilleas are for the most part natives of Australia, and are all plants of a shrubby character. The best known species is Grevillea robusta, which is largely grown for the sake of its beautiful fern-like foliage. It is, however, from a flowering point of view that some of them claim recognition. Two species that bloom during the early spring months are among the hardiest of all Australian shrubs. They are G. rosemarinifolia, with reddish flowers; and G. Juniperinæ, or sulphurea, in which they are pale yellow. Both of these do well near the sea, especially in the milder districts. One that will in a greenhouse flower throughout the winter and well on into the spring is G. alpina, a dense bush with narrow greyish leaves and curious reddish and yellow flowers. All the grevilleas are remarkable for the strange curved shape of the blossoms.—W. T.

IVIES IN GARDEN DECORATION.

Undoubtedly the ivy is one of the most beautiful of the hardy evergreen climbers, and it is to be seen growing almost everywhere either in a wild or cultivated state. Perhaps it is seen to its best advantage when growing naturally in woods, although there at times it becomes a veritable nuisance amongst timber trees, but the fact of it being a nuisance in such instances does not detract in any way from its merits as being a most charming and useful climber. The ivy can be used effectively in numerous ways, and with the many varieties available to select from it is possible to grow it successfully in almost any situation, choosing for exposed positions strong free-growing varieties, using the more delicate kinds in places where they will be somewhat sheltered.

No other climber is so useful for forming festoons on the edges of terraces, and, owing to the rapid growth of many of the varieties, it is possible, in a remarkably short space of time, to obtain a most beautiful and lasting effect at a quite modest outlay. On wide terraces, where some suitable structure does not already exist for training ivy in the manner just stated, the following simple method will be found to answer admirably. In the first place, upright posts should be firmly fixed about 15 feet apart, and from 9 to 10 feet in height; to the tops of these attach either a chain, rope, or stout wire, in such a manner as to allow it to hang in festoons; between these posts a rustic fence can be erected from two feet six inches to three feet in height, the woodwork of which should be arranged close enough to allow ample opportunities for fixing the shoots by tying and entwining. In the case of narrow terraces it is sometimes best to do without the rustic fence entirely, using only the upright posts supporting the festoons. Judgment is here necessary to decide on the height of these posts, in some instances from thirty inches to four feet will be most suitable. Ivies that are best adapted for this purpose are those having a free and vigorous habit, such as canariensis (Irish Ivy), palmata, and lucida. If good sized plants are procured and planted in fairly good soil they will in a short time, with careful training, produce the desired effect.

One of the most useful purposes to which ivy can be put is to cover bare ground under trees. Owing to the usually exhausted condition of the soil, and the dense foliage overhead, very few plants or shrubs will thrive, especially under the beech and chestnut. But if some trouble is taken when planting ivies in such a position, by either digging out holes about three feet square and filling them in with good soil or by making mounds on which they can be placed—this latter course being preferable, so as to give the plants a good start—they will without any further attention form a dense carpet. The ivy will cover all bare ground, and always present a fresh and green appearance. Steep banks and cuttings where scarcely anything will exist in hot, dry weather, when planted with ivy become in time entirely covered. This not only hides the bareness of the ground, but prevents the action of frosts crumbling away the surface soil. It is necessary to well establish the plants in good soil. The Common Ivy (Hedera helix) will be found most suitable for growing on sloping banks, as will the Irish ivy.

In some places quite a feature is made by growing specimen ivies on lawns; this is usually accomplished by training the plants to stout stakes of wood or iron, the latter being preferable on account of their durability. The stakes are so arranged as to form a pyramid, over which the shoots of the ivies are trained evenly until the stakes are entirely covered. The height of these pyramids vary according to the position and the choice of varieties. Well-grown specimens treated in this way are always admired, and varieties such as Rægneriana and dentata will be found to give a most noble effect, as with their vigorous habit it is possible to grow them into huge specimens, and by using some of the more delicate and variegated varieties in a similar manner, these, too, will be found very effective. Fine specimens are also formed with tree ivies. These have an additional charm by their freedom of flowering and setting berries while in a young state. Strong examples planted singly in good soil soon make large shapely heads. They thrive in almost any position, and are very effective when grouped with other shrubs in large beds or borders, also when judiciously planted on large rockeries, their restricted habit of growth making them especially suitable subjects for that purpose. Both the silver and golden variegated varieties of the Tree Ivy (aborescens) are very desirable, also the one bearing yellow berries.

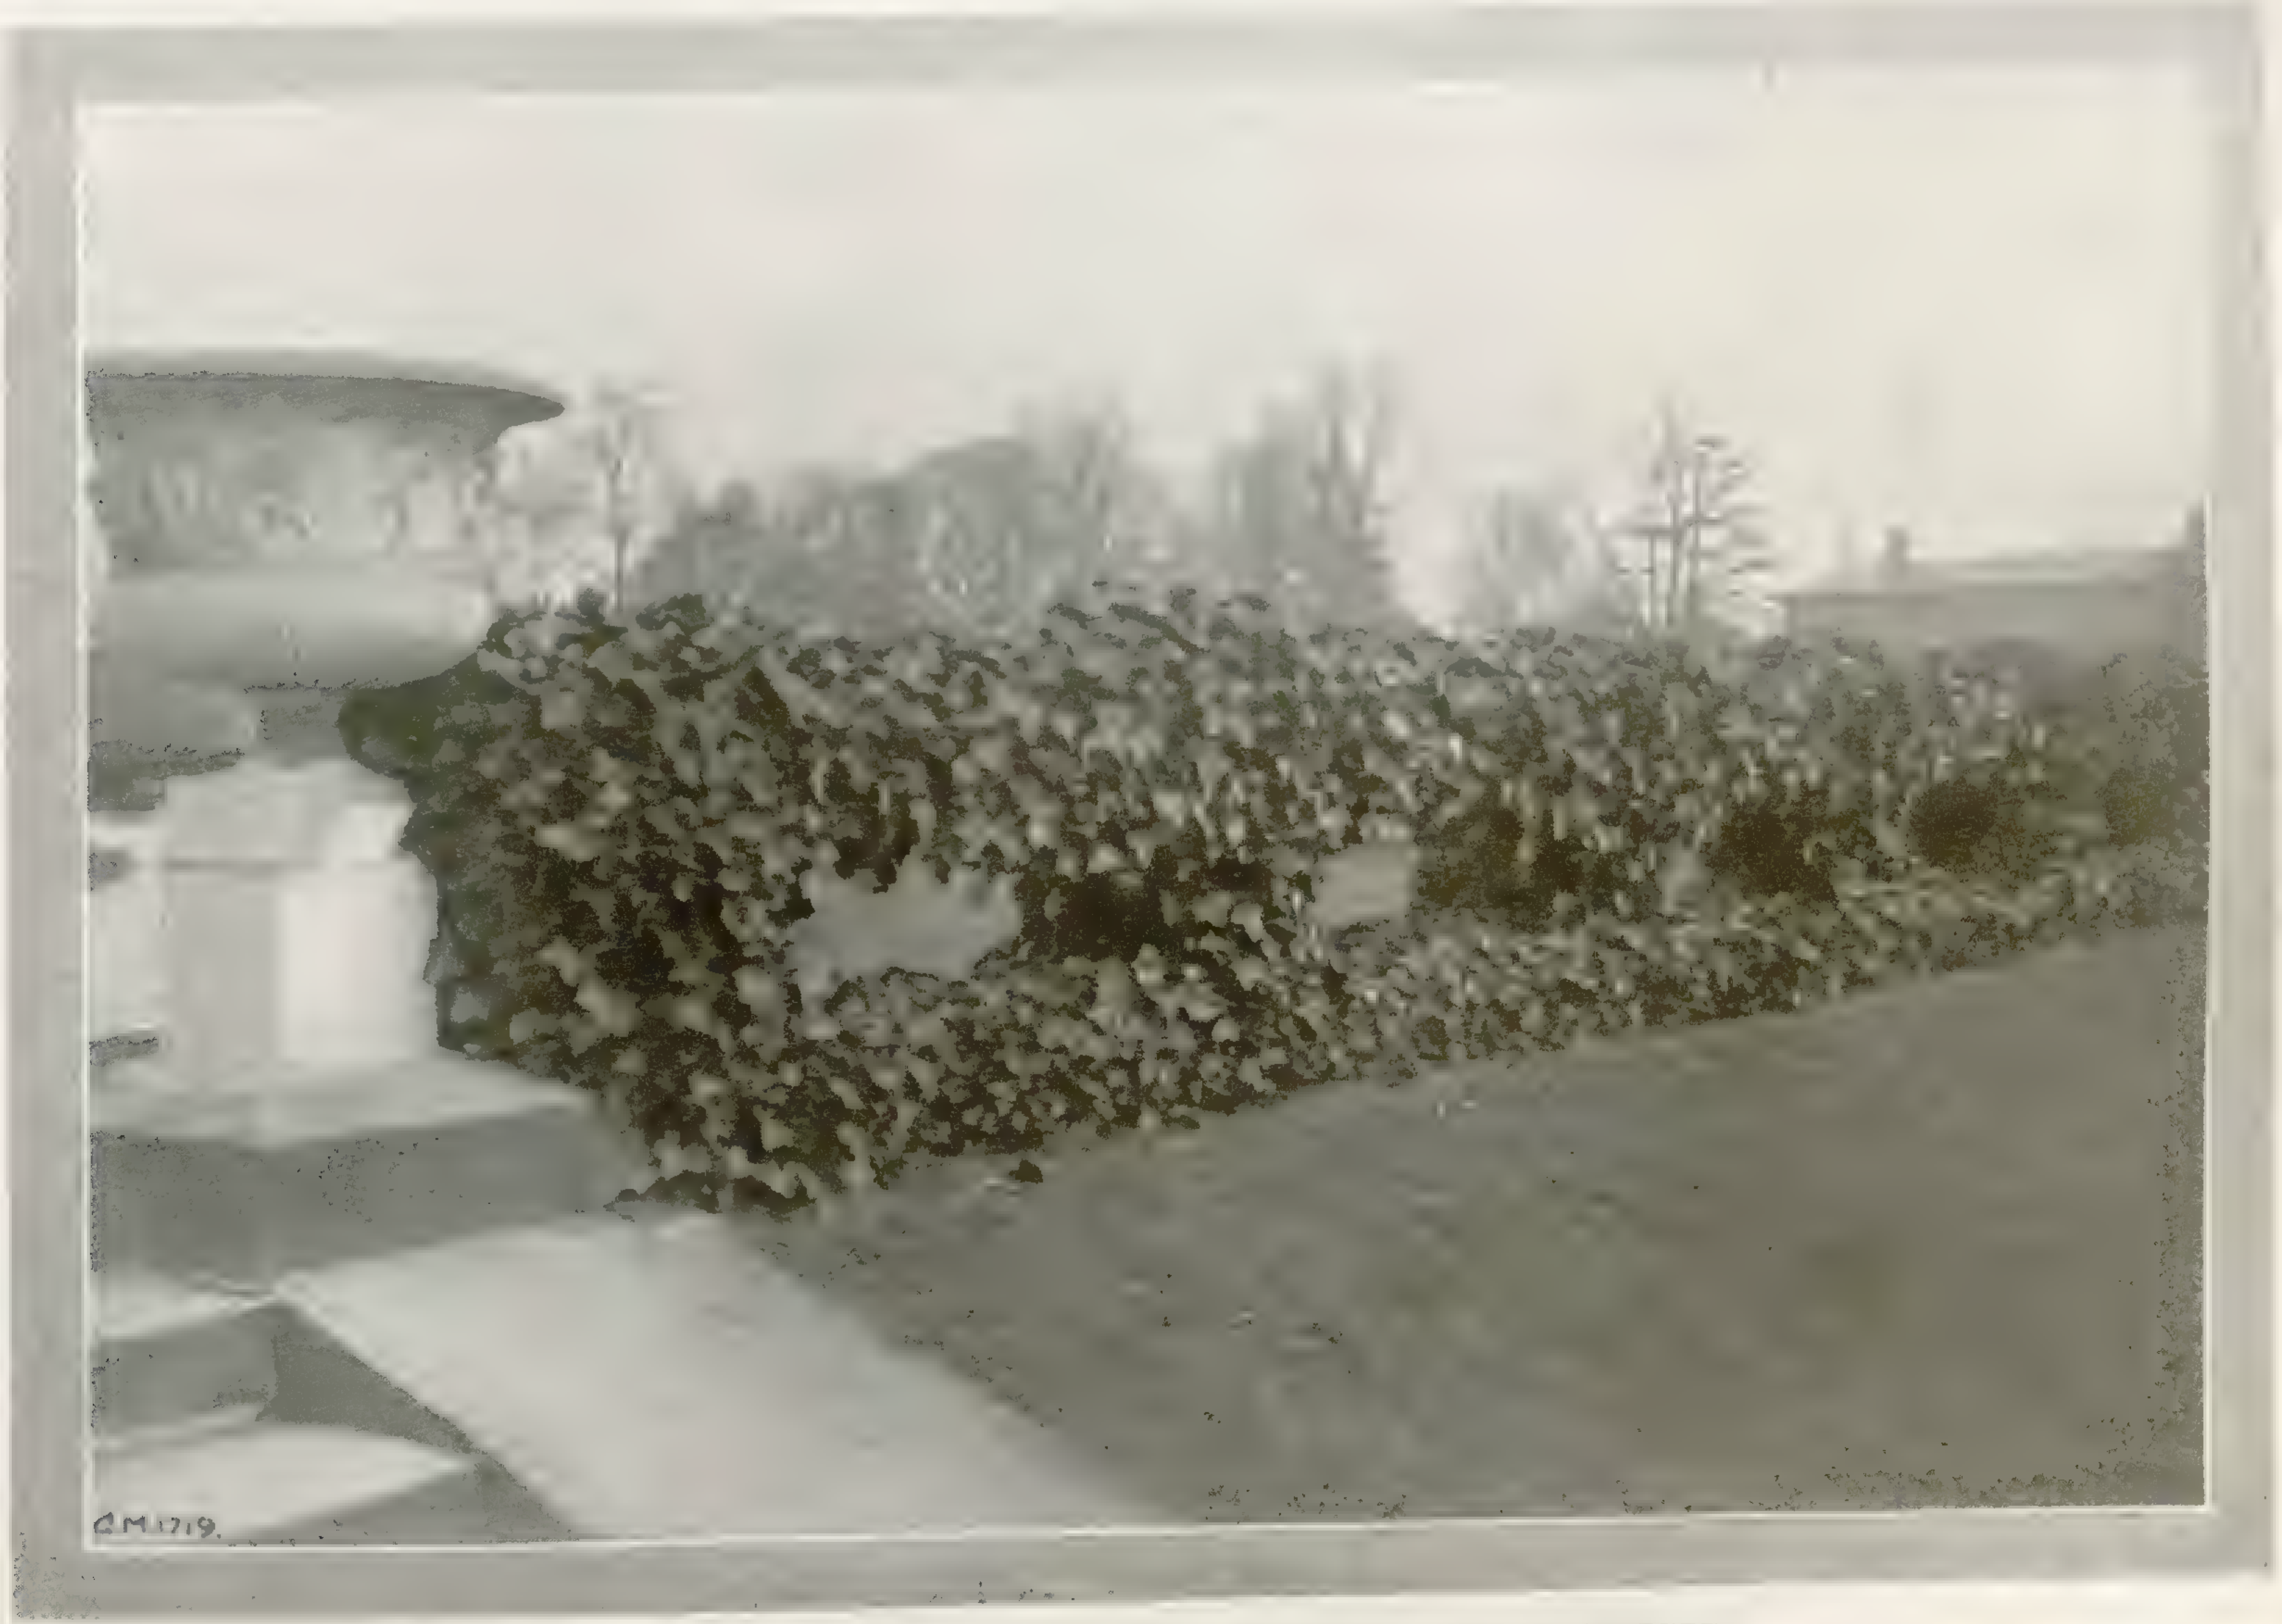
When ivies are planted near the base of old tree stumps and allowed to clamber over them naturally, they are then seen to great advantage, and form a most picturesque addition to the wild garden. By selecting positions which are somewhat sheltered it is possible to grow the most delicate and highly variegated forms to perfection in this manner, and at no other time do the variegated forms present a more pleasing and brighter appearance than when treated in this way. All varieties with the exception of arborescens lend themselves to this method of culture.

Modern architecture is not altogether too kind to this class of climber, as one often sees on damp-proof walls ivies badly infested with an attack of red spider, in some instances scale, especially so on plants situated in a sunny position. Even the strong-growing varieties against a wall having a north aspect are not immune from the ravages of these pests. Sometimes we see indications of them on plants growing against old solid walls, but no doubt the more modern style of building has greatly aggravated these conditions, and when treating with walls of this description it is advisable to exclude all the forms that have not a robust constitution.

This by no means exhausts the many useful purposes to which ivies can be put, as much might be said regarding their merits for covering arbours, for planting judiciously on pergolas with other climbers of a deciduous character, relieving the bareness of such structures in winter; the large-leaved varieties are indeed excellent for this purpose if kept well within bounds. Some varieties, too, are used to form edgings to large beds devoted to shrubs; these present a neat appearance when kept in order. In fact, no class of hardy climbers can be used in a greater variety of ways. Ivies thrive in almost any soil, but a little care should be taken not to have it too rich for the variegated varieties, as they colour best on soils of a poor nature. Planting can be successfully done at almost any season of the year, owing to the fact that nurserymen usually supply the plants established in pots.

It is important that ivies growing against walls, trellis-work, etc., should be clipped in April of each year. This operation causes them to present a bare appearance for a short time, but it is very beneficial to them and also admits of their being kept within bounds.

T. B. Field.



THE IRISH IVY (HEDERA HELIX CANARIENSIS).
Trained as a margin to a narrow terrace at Kew.

APPLE ROUNDWAY MAGNUM BONUM.

For some years past Messrs. G. Bunyard and Co., of the Maidstone Nurseries, have in their catalogue highly eulogised this apple as a late-keeping dessert variety, equal to, or even superior to, Ribston or Cox's Orange Pippin in flavour. Some cultivators have from time to time in the horticultural press had the temerity to doubt this, and I, for one, considered the statement somewhat exaggerated. Last autumn, having about a bushel of well-ripened fruits, for which, owing to the plenitude of other sorts, there was no special need throughout the winter months, I determined to test their keeping qualities and value for dessert late in the season. Accordingly none were used until the close of March, and when sent to table the firm, well-coloured, and richly-flavoured fruits were much admired and appreciated, and subsequent enquiry as to identity, while regret was expressed that the supply was limited.

At the present time—mid-April—most of the fruits are used, but, to all appearance, they would have kept plump and in good condition until May was well advanced. The fruits were grown upon a bush tree in the open garden (I have but one in bearing), which seems a very suitable form, as being of a rather spreading, shapely habit, no difficulty is experienced in keeping it to a pleasing outline. The tree in question is about ten years planted, and has borne several crops of fair-sized handsome fruits, and, although a heavy crop was produced last year, the promise at present, by way of a plentiful supply of flower buds, is all that could be wished for.

James Day.

CHOICE HEMEROCALLIS.

Hemerocallis, or day lilies, have increased so rapidly of late that there are now quite a number of varieties deserving of cultivation, indeed no herbaceous border is complete without several, and it is not easy to form a collection without including at least a dozen sorts. The flowers are somewhat ephemeral, but as they are produced so freely, and in rapid succession, the shortness of their life can scarcely be regarded as a fault.

The bulk of the species are from China and Japan. For cutting they are not very useful, as they look untidy quickly. All the species are easily grown in good garden soil, deeply dug and well enriched with farmyard manure, except H. aurantiaca major, which requires a light sandy soil or special preparation in heavier material, as the cold heavy soil causes its thick fleshy roots to decay in the winter, and the plants do not start freely in spring.

Propagation is easily effected by division of the roots; every small piece will grow if taken off with a small root attached. Hardly any varieties or species require supporting, as their flower stems are usually so stiff, even in the taller-growing kinds, that they give little trouble.

The following are all desirable: H. Apricot is one of the best varieties in cultivation, flowering remarkably well over a long season; in growth it is two feet high, and the flowers are rich apricot in colour. H. aurantiaca major grows vigorously, producing spikes four feet high; many of the blooms are six to eight inches in diameter, and as many as a dozen are produced on one stem. As previously stated this should have drainage provided where the soil is heavy. H. Thunbergi is a late-flowering kind, therefore valuable for that reason; the pale sulphur-coloured flowers are pleasantly perfumed. H. Sir Michael is a late addition to the day lilies, and has large clear yellow blossoms, reminding one of Lilium sulphureum in shape. H. luteola is a hybrid from H. aurantiaca major and H. Thunbergi. Its colour is golden-yellow, and its flower stems are from three to four feet high. H. Dr. Regel is a distinct, broad-petalled hybrid, giving its rich glowing orange blossoms in August. H. flava is the common species so much grown, and one of the oldest; it was introduced in 1596; colour, clear yellow.

H. aureole is a Japanese kind, giving a number of branching spikes, with many deep glowing orange flowers, each with a ruddy reverse. H. Dumortieri grows one foot high, and blossoms abundantly; it is compact, and useful for the front of the border. The flowers are orange-yellow, tinged with brown on the outside. H. Middendorfi has deep golden-yellow flowers, freely produced in summer. H. graminea is suitable for the rockery, growing but six inches high; the flowers are yellow, tinted green. H. disticha flore plena opens its semi-double, tawny-coloured flowers late in summer. E. M.

HEDERA MADERENSIS VARIEGATA.
A distinct and beautiful ivy, the leaves finely marked with silvery white.

SAXIFRAGAS.

The saxifragas are what I may term very substantial plants, because they make a border look furnished when first planted out in it, and afterwards continue to spread until much surface of both border or rock-work is covered. Not only are the leaves diverse in form and very beautiful, but the flowers of some are charming.

In several districts in Hampshire where the soil is light and sandy, with a gravelly subsoil, I have found saxifragas thriving splendidly in extremely hot seasons while many other kinds of plants were looking very dejected. On a steep bank in one garden a number of shallow pans (which were cracked or chipped, and consequently rendered useless for seedlings or for plants in the usual way) were fixed, but not in such a way as to look very formal, and saxifragas were luxuriating in them. Altogether, the bank, with a slope of about 15ft., was one of the most attractive I have ever seen in a garden. The surface was more or less undulating, and the miniature-leaved and large-leaved plants were so disposed as to look natural, and still further lend to the bank an informal and even rugged appearance.

The spring is a good time for the work of dividing clumps. A light fibrous loam, with a small quantity of leaf-soil added, should be used if procurable. Peat is also good, but it should not be added in too great quantity to the loam, except in instances where the position is naturally low and damp.

The following are good saxifragas for forming a new collection.: Saxifraga cæsia major, flowers in May and June; S. ceratophylla, June; S. ciliata, March to May; S. coriophylla, March; S. Fortunei, October, and later if the weather remains comparatively mild; and S. ligulata, with beautiful large leaves, and flowers borne on spikes resembling, somewhat, that of a hyacinth, March to May. S. longifolia, one of the very best, has been called the Queen of Saxifragas, it is a species that thrives even in a wet situation, the leaves are massed together, rosette-fashion, but there is nothing stiff about them, as the individual leaves are narrow and pointed; it flowers in June and July. Other good things are Saxifraga mutata, June to August; S. paradoxa, May and June; and S. peltata, June. Saxifraga purpurascens has very large leaves and is a noble example to use as a dot plant; April to June. S. pyramidalis is very beautiful, it bears flowers on spikes somewhat similar to those of Spiræa japonica, in June and July. S. Wallacei flowers from April to August, and London Pride, S. umbrosa, will grow freely under trees, and where the soil is fairly rich the flower spikes are large and branching and suitable for cutting.

George Garner.

THE HOLLIES.

The important position occupied in gardens and woodlands by the common holly overshadows the virtues of many other species which in themselves are worthy to rank amongst the most useful evergreens suitable for garden decoration in the British Isles. Neither is it as evergreens alone that the value of these various kinds of hollies has to be determined, for the fruit in some instances is quite as beautiful as that of the common kind, whilst several species are deciduous, and their importance centres entirely in their bright coloured berries. The various hollies are included in the genus Ilex, a family rich in species, which has its headquarters in South America, Brazil alone claiming sixty of the 167 described species. The others are widely distributed, for representatives are found in each of the following countries: Europe, West Indies, Malaya, Australia, Polynesia, Himalaya, China, Japan, Formosa, N. America, and N. Africa. A great many of these are unsuitable for outdoor culture in the British Isles, but in addition to the European kind, those from the United States, and several from Japan, China, the Himalaya, and the Azores give satisfactory results in various localities, though all may not be grown in the colder districts.

With the exception of their ornamental qualities and for hedge making, the hollies cannot be said to be of any other use in this country, though the wood is very hard and durable, and, if it could be obtained in quantity it would probably find a place amongst commercial timbers. At one time it was used by the turner for various purposes, and also for inlaying. Young straight shoots are in some request for making into walking-sticks and whip-handles, whilst at one time the bark of the common holly was used largely in the manufacture of bird-lime. In other countries the bark of various species is still used for the same purpose, and at the recent Japan-British Exhibition in London numerous samples of bird-lime prepared from the bark of Ilex integra were shown, together with bird-lime manufactured from the bark of Trochodendron aralioides, the two trees being known as bird-lime trees. In South America a kind of tea known as Maté or Paraguay tea, is prepared from the leaves of Ilex paraguayensis. This is stated to occupy an important position amongst the products of the country, and to be held in similar esteem to ordinary tea in other countries. "The Treasury of Botany," second edition, gives the annual consumption in South America at the time of publication at 8,000,000 lbs.

Fruits and Leaves.

Ilex aquifolium, the Common Holly, is such a familiar object in gardens and woodlands that it is known to everybody; yet, though so well known, some of its peculiarities do not appear to have been generally recognised if we are to judge from questions which are constantly occurring. The question as to why one specimen should fruit freely and another one be barren often arises. This, however, is accounted for by the fact that, generally speaking, hollies are diœcious, the male flowers appearing on one plant and the female flowers on another. This distinction breaks down sometimes, for now and then perfect female flowers are borne by specimens on which the majority of the flowers are males; the same thing occurring in the opposite direction. An examination of the flowers readily indicates the sex to which a particular tree may belong, for, though in male flowers female organs are present, they are very rudimentary in character, whilst the male organs are well developed and bear a large quantity of pollen. In female flowers, on the other hand, the female organs are prominent, and the stamens immature. Female flowered trees some distance away from male trees frequently perfect large crops of fruits, a fact which has given rise to the idea that trees are often monœcious. An examination of the flowers of such trees, however, has failed to provide evidence in support of this theory, whilst the very small percentage of fertile seeds found on such trees indicate that pollen has been carried by insect agency, but not in sufficient quantity to effect general pollination. It also emphasises the fact that fruits may swell to their normal size and ripen without containing fertile seeds. Where flowers containing mature male and female organs have been noted, they have usually been borne later than the normal flowering time. One particular example of the Himalayan Holly, Ilex dipyrena, has been under observation for some years. This is a male-flowered tree, but most years two or three fruits may be collected from it. A female plant of the same species growing some distance away rarely perfects a seed, though it never fails to produce normal-sized fruits and frequently a good crop. This lack of fertile seeds is probably due to the species blossoming in advance of other hollies and the insects necessary for pollination not being available.

ILEX ALTACLARENSIS.
A large-leaved green holly, remarkable for its free growth and effectiveness.

Another peculiarity of the common holly which does not appear to be generally understood, is its habit of producing leaves of vastly different outlines. The character most commonly associated with the leaves of the holly is its intense spininess, yet it may also be found with leaves almost or quite destitute of spines. When the latter character applies to a whole tree, it has been thought to indicate a different species. This, however, is not the case, for, as a holly advances in age, the spines peculiar to its youth disappear, and spineless branches occur. The phenomenon has been explained as a provision of nature for the protection of young plants from attacks by animals, and weight is added to the explanation by the fact of the lower branches of old trees bearing spiny leaves, whilst those of the upper branches are spineless. By propagating from these spineless branches, trees bearing wholly spineless leaves have been obtained. The Common Holly (Ilex aquifolium) is widely distributed through Europe, and a variety of it has been found in China. It is a native of the British Isles, and attains its largest dimensions in various parts of England and Scotland. It is often found in woods associated with oak, birch, or Scots pine from the South of England to the

North of Scotland, whilst it has been noted in companionship with birch on the wild hill sides of Skye. In Hertfordshire, Buckinghamshire and other counties it is frequently found as a hedge-row tree 15 to 25 feet high, with a trunk 9 to 15 inches in diameter. Growing in woods it attains larger dimensions, and may frequently be seen between 35 and 55 feet in height, whilst trees 70 to 80 feet high have been recorded. It is probable that the height of many trees would be greater were it not that berried branches are in such demand at Christmas time, and that terminal branches are not spared when holly is being gathered for market.

ILEX AQUIFOLIUM AUREA REGINA

An effective variety with rich yellow variegation, popularly known as the "Golden Queen Holly."

Cultivation.

Providing certain conditions relating to transplanting are observed, the cultivation of hollies is not attended by serious difficulties. The family, as a whole, is impatient of root disturbance, consequently transplanting must be done at a period when the minimum of risk from this source will be run. This is when the health of the tree presents its most vigorous aspects, and it is in the most favourable condition for repairing injury to roots and the attendant reduction of the food supply. Two periods of the year present themselves as being superior to others. The first and best is late April and May. The first fortnight of May may be taken as a medium, but a week or two earlier or later may be desirable in different parts of the country. An examination of the plants will reveal the correct time, for it is when the young growths are beginning to push that transplanting should be accomplished. The second period for transplanting is the end of August and the beginning of September just as growth is completed. At this time also root injury is quickly repaired. Providing trees can be removed with large balls of earth attached to the roots, transplanting may be done at almost any time, for the danger of root disturbance is thus minimised. Ground ought always to be prepared beforehand so that on the arrival of the plants they may be inserted without delay. Should the roots be dry, a good watering must be given previous to planting, and in any case a sufficient amount of water should be provided afterwards to settle the soil well about the roots. In the event of hot, dry weather being experienced, the newly-planted trees will be benefited by a good syringing each morning and evening for a few weeks. A mulch of decayed manure and leaves applied to the surface of the ground will assist root action by keeping the soil cool and moist. In the case of good-sized specimens being removed with little or no soil, some means should be adopted of keeping them from being blown about until new roots have been formed. In some cases stakes may supply the need, in other instances a triangle of ropes secured to stakes driven in the ground may be necessary, whilst for hedges, one or two strands of strong wire run along, and secured to stakes here and there, will be found useful to tie the plants to.

Pruning of hollies needs to be done with extreme care. Too often the trees are clipped into hideous cones or globes, and nothing of the natural outline remains. This may be obviated by letting pruning take the form of thinning out rather than a general cutting back. Should a bush be outgrowing its position or certain parts be developing at an abnormal rate, then, instead of hard clipping such as is done to a hedge, let the operator remove certain branches bodily. This will leave behind a free and natural appearance, and even if a hole is made it will soon fill up again. Late spring is the best time to prune, for then the new shoots quickly hide the cuts, and any stiffness which may be apparent is soon relieved.

Propagation of the species is effected by seeds, but the many garden varieties must be increased by cuttings, by grafting, or by budding. The former is the better method, for in the latter cases there is always the danger of suckers arising from the stock, which, if not attended to soon overgrow the scion. Cuttings of partly ripened shoots may be taken in July and inserted in sandy soil in a cold but close frame. They will not be ready for removal from the frame for at least nine months. For several years careful attention must be paid to the leaders of young plants raised from cuttings, or no proper central stem will be formed, the tendency being to develop a bush-like habit.

Varieties of Ilex aquifolium.

Upwards of one hundred varieties of this species have been described within the last century and a-half. During the last thirty years of the eighteenth century there appears to have been a brisk demand for varieties, and from old publications we gather that several nurserymen about that period raised and collected new varieties assiduously. Some of those varieties exist at the present time, though not under the same names, the tendency having been to create descriptive names in place of the popular ones of that time. We, however, still find some lingering as second or popular names to present-day varieties. Cases in point are "Hedghog Holly" and "Milkmaid Holly." The numerous forms are distinguished in various ways; some differ in size or degree of spininess of the leaves, others by habit, and others again by variegated foliage. The latter set is again divided into distinct groups by silver and golden variegated leaves, whilst the position of the variegation determines the varietal names of some kinds. In those instances where the variegation is found in the centre of the leaves there is always a greater tendency for a plant to revert to the type by producing branches without variegation than when the colouring is found near the margins and the centres are green. Why this peculiarity should occur there would appear to be no good reason, but such will be found to be the case if the various kinds are kept under observation. When branches do revert, they should be removed at once, or they will exert a harmful effect on the tree. There is no necessity to refer to a long list of varieties, but the following kinds might well be admitted into any garden.

I. a. fructu-luteo, commonly called the Yellow-berried Holly, was discovered wild several centuries ago in a wood near Wardour Castle, Wiltshire. Except that its berries are yellow, it is a counterpart of the type.

I. a. camelliæfolia is one of the most handsome of the stronger-growing varieties. Of pyramidal outline, it is readily recognised amongst other kinds by reason of its dark olive-green glossy leaves which may be spineless throughout, or bear a few irregularly placed spines on the margins. It is a fruiting variety.

I. a. donningtonensis is a male kind, which originated in the Handsworth Nursery, Sheffield. This variety has narrow, deep green leaves, which are scarcely more than three-quarters of an inch wide. The margins, though usually entire, sometimes bear a few stout spines.

I. a. laurifolia.—This, the "Laurel-leaved Holly," is distinguished by its dark-green spineless leaves, which are smaller and thinner than those of I. a. camelliæfolia.

I. a. myrtifolia introduces another type of holly, for it represents a set of low, bushy kinds, which are recognised by small spiny leaves that are rarely more than $1\frac{1}{2}$ inches long and often less. This, and others belonging to the same set, are useful where compact, slow-growing evergreens are required.

I. a. ovata is peculiar by reason of its regular sized ovate leaves, armed with short spines distributed at regular intervals along the margins. It forms a shapely bush, and is of very distinct appearance.

I. a. aurea marginata.—Broadly speaking, all the varieties with golden marginal variegation are included under this heading, but such a variation of size of leaf, degree of colouring and habit are found that many kinds have been given distinctive names. Some are abundantly distinct one from another, others are not, while some differ simply by being male or female kinds. So close are some varieties to each other, that it is possible to gather specimens from several named varieties, and match them on a single plant which is variable in habit; yet there is a peculiarity of growth about each variety that is sufficient to make it distinct from its neighbour. On typical aurea marginata the leaves are as large as those of the common holly with somewhat less ferocious spines. The centre of the leaf is green, with a wide irregular-shaped band of gold around the margin.

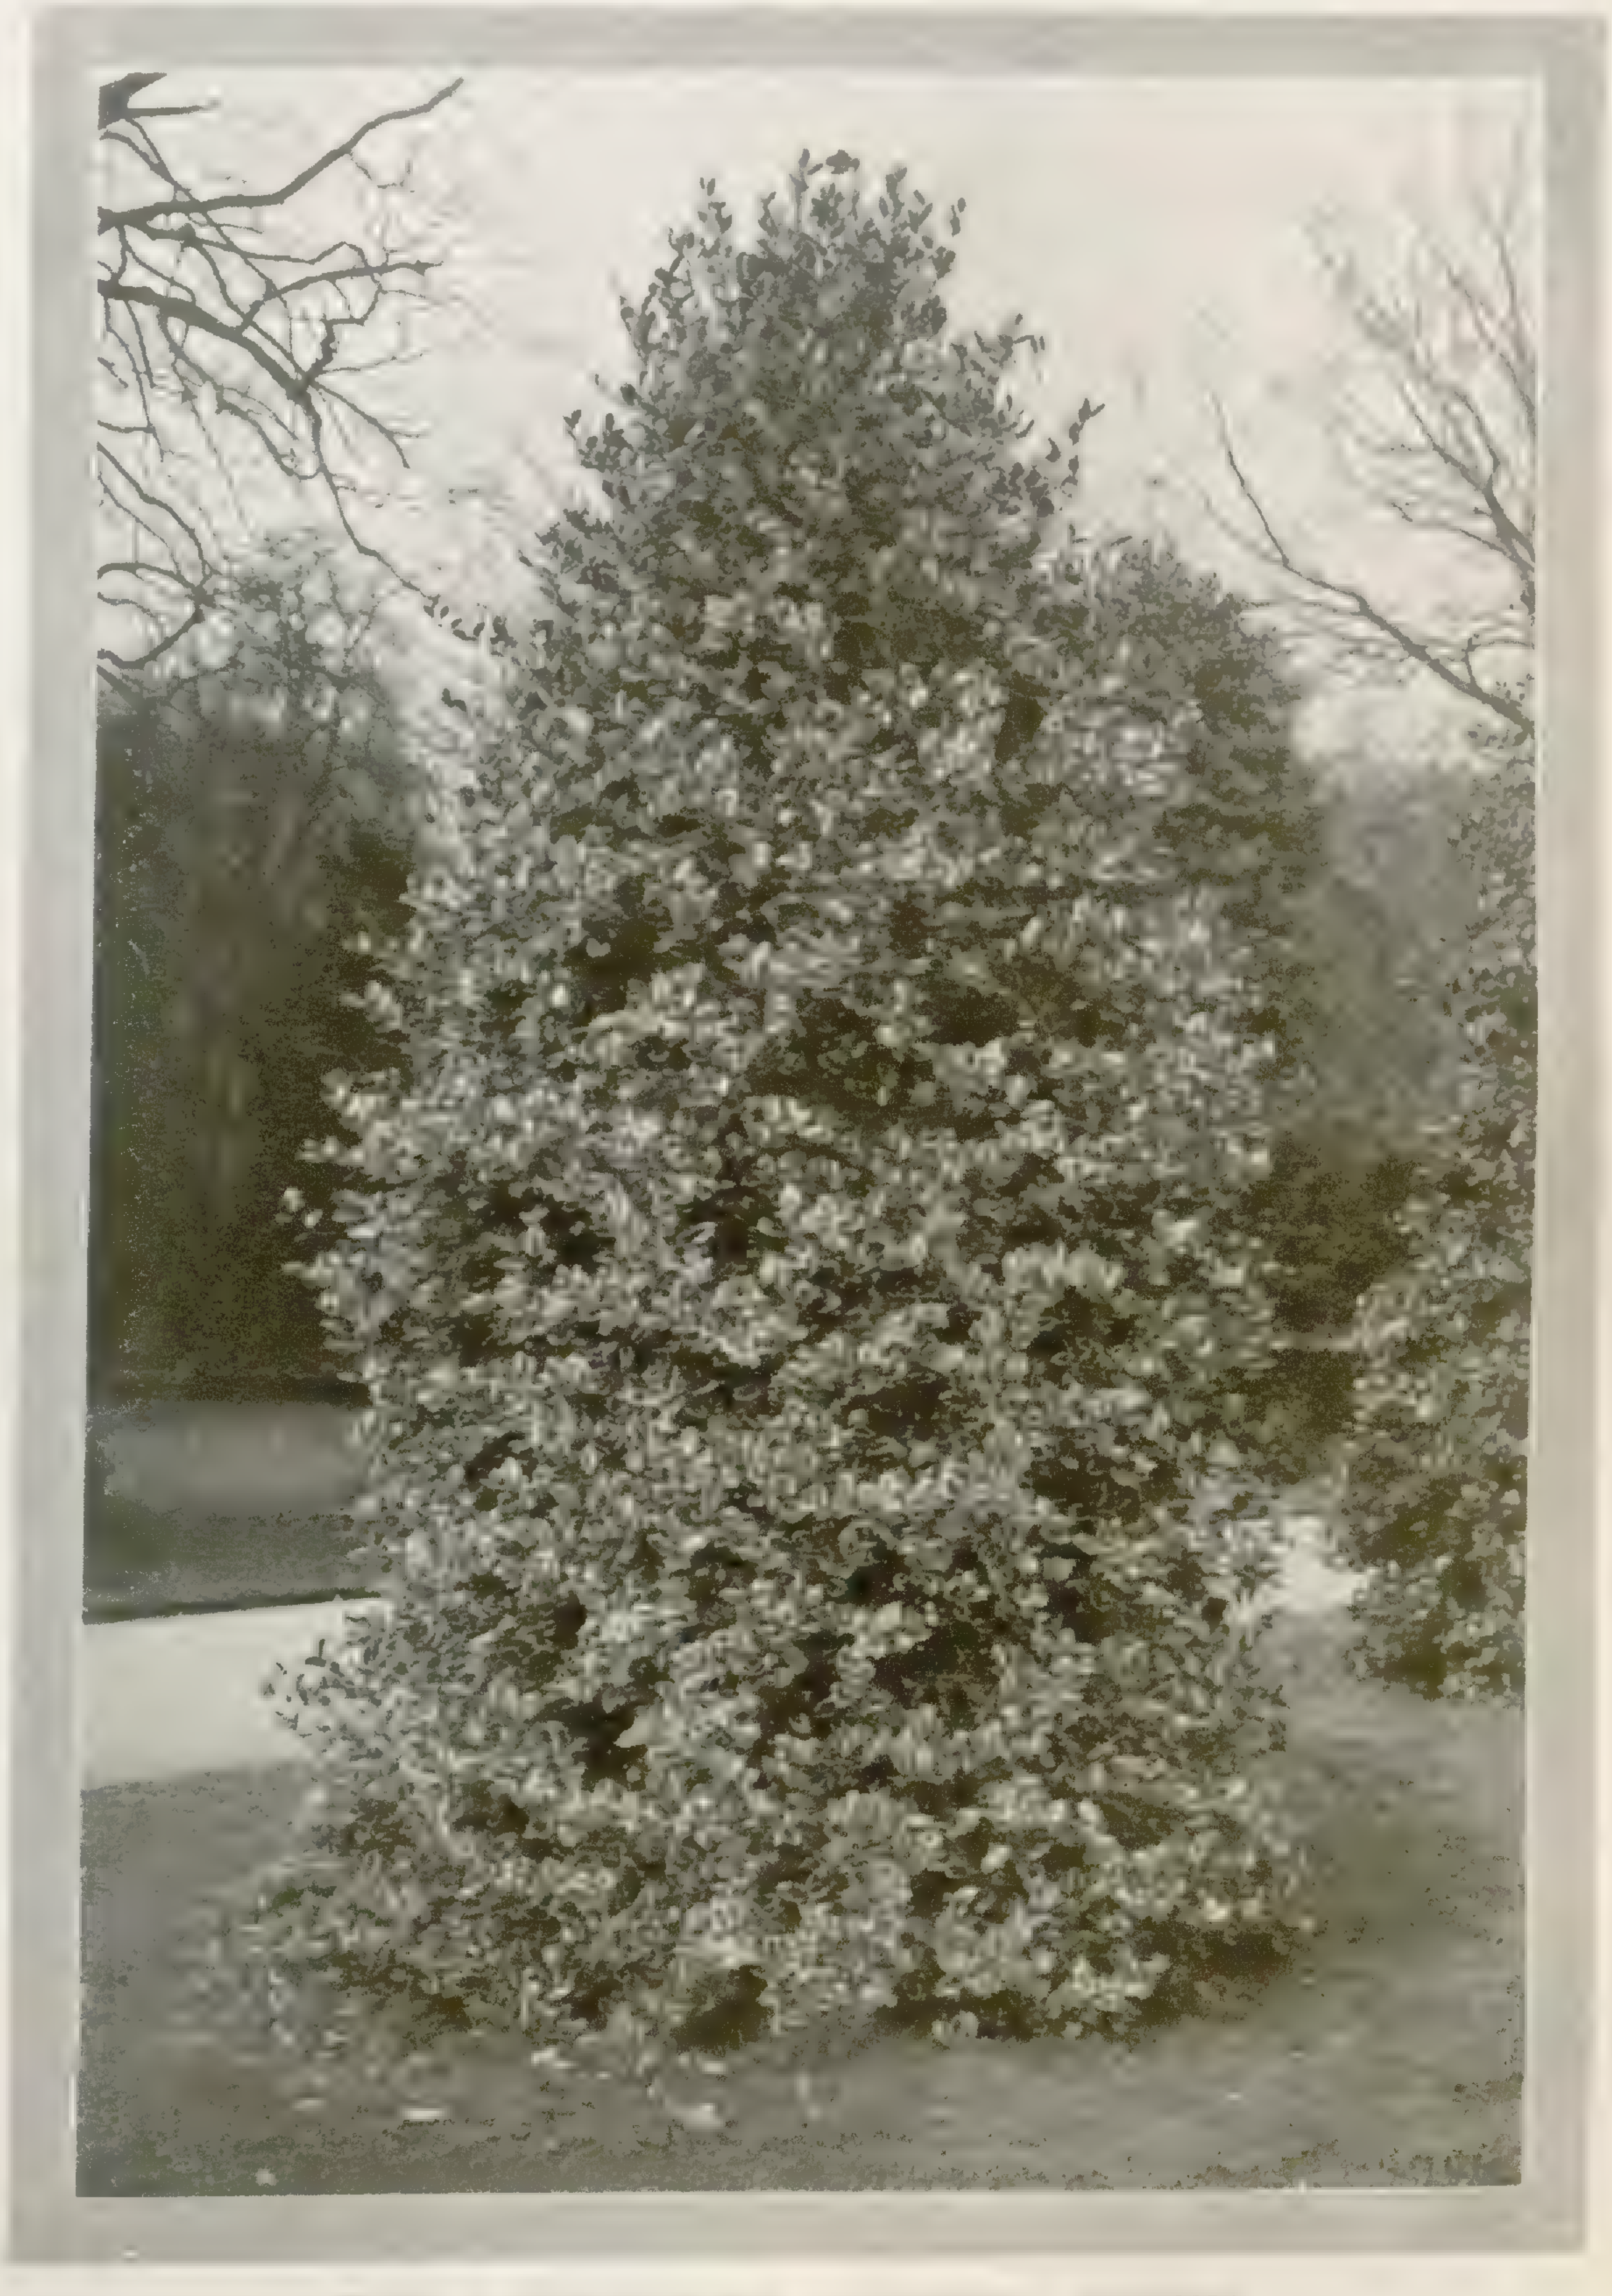
I. a. aurea regina, "Golden Queen Holly."—Where one golden-leaved holly only is required, this is the one which should be selected, for not only is it of vigorous habit, but the colour is wonderfully rich and well developed. The centre of the leaf is mottled with grey and green in an irregular manner, whilst the broad band of gold surrounding the margin mixes with the other colours at varying depths, sometimes extending well towards the middle.

I. a. Watereriana is distinct and easily recognised, for it is of compact habit, of slow growth, and keeps shapely with little attention to pruning. The leaves are more or less ovate, up to $2\frac{1}{2}$ inches in length, and somewhat more than an inch wide. The spines are not numerous, and what few appear are not of a ferocious character.

I. a. argentea-marginata.—The remarks passed about aurea marginata apply also in this case, for the variety exhibits wide variation. It is a quick-growing and useful variety, its silver-margined leaves making it a conspicuous object.

I. a. argentea regina is well known as "Silver Queen Holly." Its leaves are more or less oval or broadly ovate, and the green centre has a generous margin of silver, or rather cream colour. As in the case of Golden Queen, it is one of the most conspicuous of its group.

I. a Handsworth Silver is a very handsome silver-margined holly. It may be distinguished by its purple bark and long elliptic-oblong leaves, armed with sturdy spines. The centre of the leaf is mottled grey and green, and the silver margin is of irregular width.



ILEX AQUILFOLIUM ARGENTEA REGINA.

A handsome form with silvery variegation, and popularly known as the "Silver Queen Holly."

I. a. pendula is a green-leaved form of the common holly with pendulous branches. The habit is of the uniform umbrella type, and a well-developed plant forms a distinct and attractive object. It is necessary to keep a leading branch tied up to get the plant to attain a presentable height.

It is sometimes the habit to use some of the above-mentioned varieties for hedges, but none of them are so attractive or so generally useful for the purpose as the common holly. Their position in the garden is essentially that of specimen plants.

Other Species and Varieties.

I. platyphylla.—Though this large-leaved holly is frequently included amongst varieties of I aquifolium, there can be little doubt but that it is a form of the Canary Island species I. platyphylla.

In all essential characters it agrees with that species more closely than with I. acquifolium, and neither it nor any of the varieties bearing broad leaves of the same type ever, so far as I have been able to learn, produce shoots which bear leaves anything like those of the common holly, whereas most of the varieties of I. aquifolium revert to the type now and then. The leaves of I. platyphylla are oval, often 4 to 5 inches long, and $2\frac{1}{2}$ to 3 inches wide, the margins being usually irregularly armed with short spines, though on some varieties the spines may be absent. Varieties are noticeable in balearica, maderensis, and nigrescens. Hybrids have doubtless originated between it and I. aquifolium, and it is probable that I. altaclarensis, I. belgica, I. Hendersoni, I. Hodginsi, and I. Shepherdi are of this parentage. Many growers consider the last two kinds synonymous, but, as they are seen in some places they show a slight variation, for whilst Shepherdi is a male form, Hodginsi sometimes bears fruit. Presuming the two kinds to be hybrids, several slightly different plants may have been raised which have been placed under one or other name.

I. altaclarensis, of which an illustration of a fine specimen growing at Kew is given, is one of the most ornamental of the broad-leaved kinds. Of vigorous constitution, it grows rapidly into a fine bush, and is distinguished by its purplish bark and deep green roundish-ovate leaves, which are up to 4 inches long and 3 inches wide, armed with strong spines. W. Dallimore.

(To be continued.)

THE BROCCOLI CROP IN SCOTLAND.

From the time of the first severe frost of the waning year, which effectually disposes of such subjects as marrows, beans, peas, and probably cauliflowers, the frequently expressed complaint from the chef, and may be from those higher in the social scale, is, that the available supply of vegetables is too much of the common kind and lacking in variety. Too often, it is feared, there are good grounds for this complaint, as, however prime in quality and acceptable the various root crops, savoys, kales, or even Brussels sprouts are when first introduced for the season, they become common, and are not highly appreciated at table when brought into every-day use.

In establishments where facilities for forcing during the winter months are not of the best, whereby the production of seakale, mushrooms and similar products are unattainable until the turn of the year, the difficulties of the cultivator are very considerably accentuated.

It may be safely assumed that in many establishments requiring and expecting full supplies of fresh vegetables at all seasons, the broccoli crop is not assessed at its full value, while on the other hand too much stress is often laid upon the possible injury to the plants from frost, whereby the ground space and labour expended is wasted. While readily admitting that there always exists the risk of loss to a portion, or in extreme instances, perhaps the whole of the crop in this way, yet, except in very unfavourable situations as to soil and climate, such loss seldom occurs.

The winter immediately preceding the one just passed was the worst experienced in Scotland for several years, for not only did long-continued severe frost prevail, but the abnormal earliness of the same, and the general absence of snow as a protective covering, told heavily upon vegetation, and green plants in particular. Apart from this very few cultivators were prepared for such an early visitation, consequently, broccoli plants in most cases were in a growing position, and the frozen condition of the soil precluded the possibility of bringing them to the customary recumbent condition of comparative safety. Needless to say under the circumstances many plants were killed outright, but others passed through the trying ordeal almost unharmed.

The winter just closed has been quite the reverse, being almost free from severe frost and very light snow falls, and at this place not a broccoli plant has suffered injury, while a daily supply of heads has throughout been obtainable, and will probably so continue well into June, when the earliest cauliflowers are expected to be ready. To have this delicious vegetable the whole year round is worthy of strenuous effort, albeit the attempt may occasionally be frustrated by influences beyond the apprehension and control of the operator.

In recent years many new names have been added to the lists of varieties, more names evidently than distinct varieties. In some cases it is impossible to distinguish even a slight degree of superiority over those older and well-tried varieties, and with many, the capability of frost resistance is not a prominent feature. For autumn and early winter use Walcheren, Michaelmas White, and Veitch's Self-protecting are all that could be desired, or if only one sort can be accommodated the last is certain to give satisfaction. Two sowings at least should be practised; the first early in April and one towards the close of the month. From these sowings the resultant plants should be transferred to a well-prepared plot of soil, a few inches apart, to gain strength, and for the further encouragement of a fibrous-root system previous to being set out permanently about two feet apart, upon well-manured and firm ground. Maggot, or grub at the root is the bane to which these are subject, and is best overcome by the free use of soot stirred below the surface, by applying water to the roots at intervals, in which nitrate of soda at the rate of one ounce to the gallon of water has been dissolved, and also by using one af the several preparations advertised for the purpose of destroying these insidious foes.

From November onwards Sutton's Superb White, Christmas White, and Snow's Winter White are all excellent, and, if sowing and planting is carried out successively these will provide a supply until February, when Leamington will probably be ready for use. The last is an old but most reliable variety, having close heads well protected by incurving leaves, which often so well envelop the curd that its presence may pass undetected. Where a few scores of this variety are grown they produce a long succession, and the purity of colouring very nearly approaches that of the cauliflower. For late use Model, Late Queen, June Monarch, and lastly Methven's June, the latest that I am acquainted with, may be depended upon to produce a large supply of heads all through the spring months.

There are others, both old and new sorts, that approach, or perhaps equal these, but few I think that surpass them upon the main points. It is prudent, however, before relying entirely upon new comers to test them for two or more seasons alongside those of well-established repute, and afterwards act according to the results obtained.

Sprouting Broccoli is distinct from all the foregoing, and once grown and tested as a cooked vegetable, would never afterwards be willingly dispensed with. There are two kinds of this, the white and the purple headed, the former being the earlier and likewise the more tender, but, as the produce is generally available for use shortly after the New Year, it is easily understood that its susceptibility to injury by frost is increased compared with its purple counterpart, which is seldom ready for gathering before the middle or end of March, and then if all has so far gone well with the plants, an abundant supply is ensured for several weeks. The treatment accorded the broccoli proper, as to sowing the seeds and after culture, suit this equally well, and as the small leaves surrounding the flower heads may with much acceptance be retained in the cooking process variety is thus obtained, though the relationship to the more stately subject is very close.

Before sowing the seeds of late varieties a decision should be arrived at as to the position the plants are eventually to occupy, and fix the date of sowing accordingly. If the ground is vacant or likely to be so, whenever the plants are of suitable size, sowing may be done from the middle of April onwards, but if other crops, as early potatoes or peas must first mature upon the site, it may be advisable to defer the sowing until May to avoid the unwelcome circumstance of the plants becoming overgrown before they can possibly be accommodated. Ground in good condition but not recently manured, is best, and, if bearing another crop, a turning over of the surface with fork or cultivator when this is cleared, is all that is necessary to fit it for broccoli, as a firm root-run induces sturdiness of growth and hardness of tissue; both so very essential to withstand excessive damp and low temperature.

Maggot or grub attacking the root is the main evil during the growing season, more especially about midsummer, when the annoying spectacle of drooping leaves here and there in a plot of otherwise healthy plants is not uncommon. Winter dressings of lime, or gas-lime are helpful.

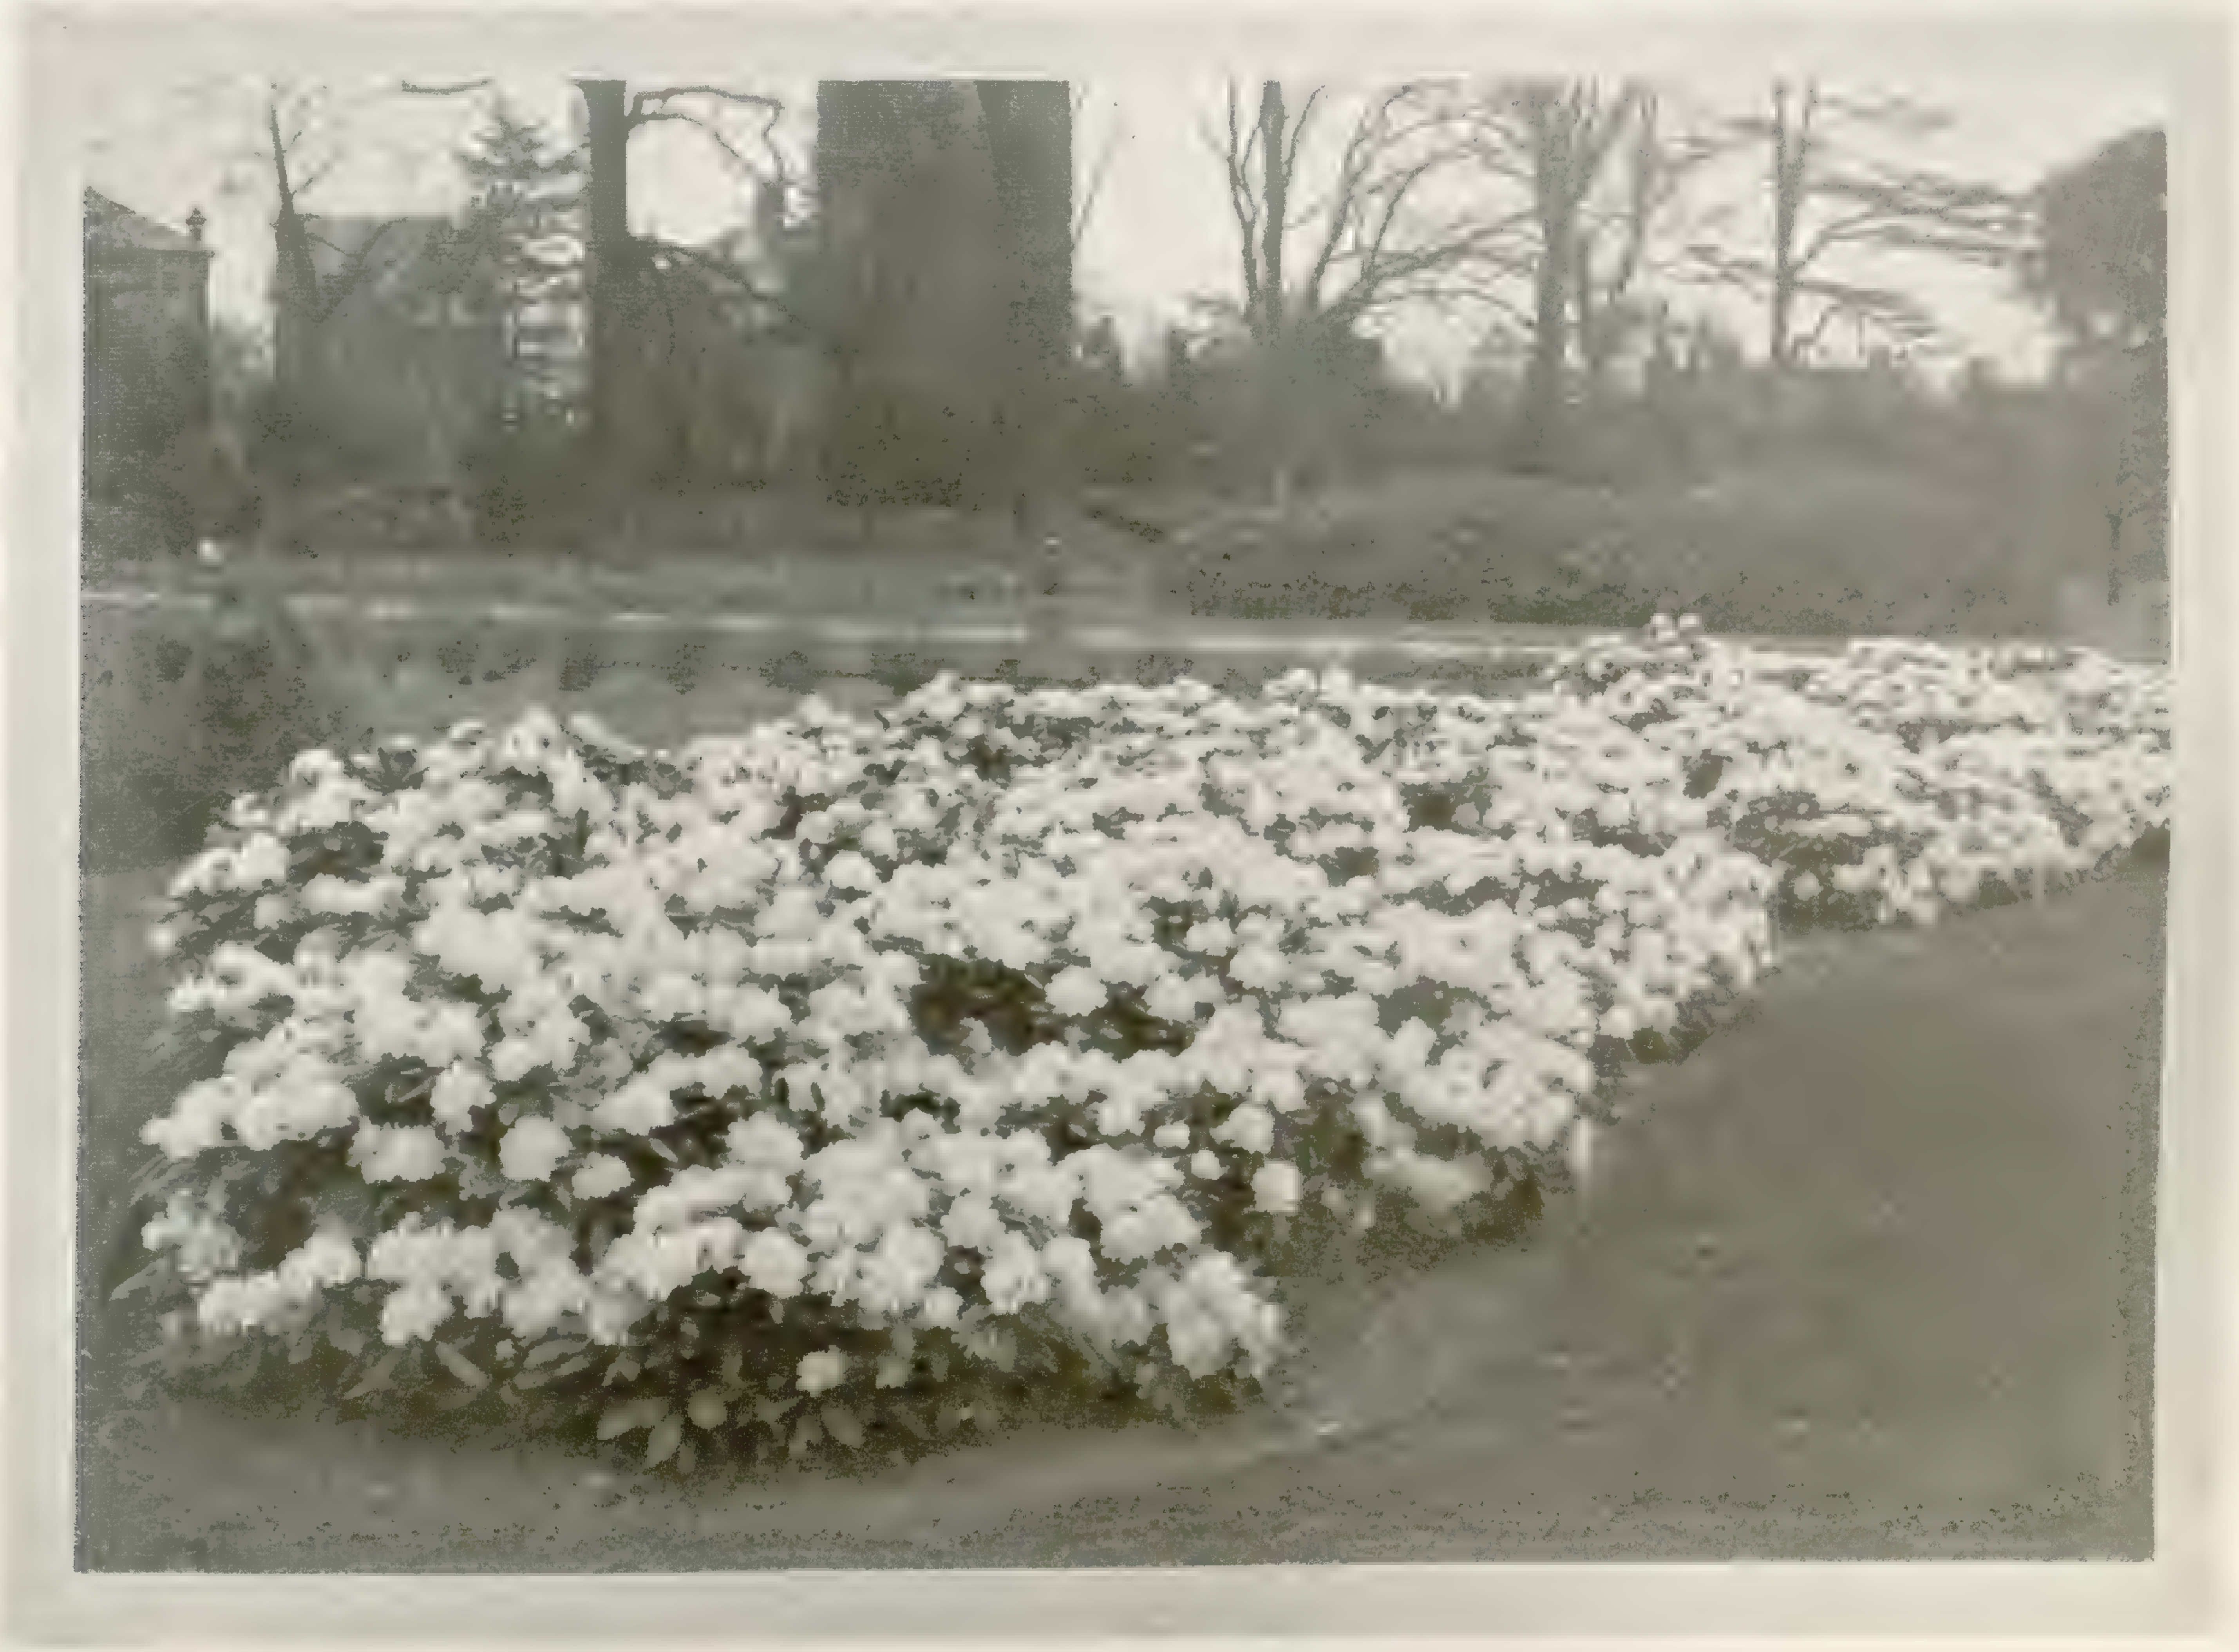
James Day.

RHODODENDRONS FOR GENERAL CULTIVATION.

To those who have taken a leading part in obtaining for the trees and shrubs remarkable for the beauty of their flowers a prominent position in the garden, it is highly gratifying to have unquestionable proofs that the rhododendrons are sharing to the full in the popularity which such subjects enjoy, and that they are now being annually planted in largely increased numbers. This is gratifying, not so much because one's efforts have been highly successful as for the knowledge that we may anticipate a material increase in the attractions of large numbers of gardens. The increase in the planting of rhododendrons has been great, but certainly not larger than it should have been, for there are many gardens in which these shrubs have not been given a place, or are so indifferently represented as to render it impossible for the owners to have any proper idea of their value as aids in beautifying the garden. It is quite certain that no one can base an estimate of the beauty and usefulness of rhododendrons as a class from a few seedling plants of Rhododendron ponticum planted in a mixed shrubbery or on the margin of a plantation.

This great group of evergreens contains so large a number of species and hybrids as to be rich in interest as well as in attractions, and a moderate collection would form a feature of considerable importance. Provided the garden is in a district enjoying a kind climate it would be possible to include a considerable number of the Himalayan species and their hybrids, and thus have a succession of flowers from quite early in the year until the beginning of July, when the little grown Rhododendron azalioides yields freely of its fragrant flower trusses. It would be interesting to refer to the formation of a collection adapted to gardens of sufficient size to allow of distinctive features being included within their area, but this would necessitate considerable space, and it has been considered advisable to confine these notes to the many fine hybrids that are so hardy in constitution that they may be successfully grown in all parts of the British Isles.

For a long period the general belief that rhododendrons, other than the pontic varieties, could not be successfully grown without the aid of peat was a most effectual check to the extensive planting of these shrubs. Good peat is an expensive commodity when used in large quantities, and it is not altogether surprising that many owners of gardens should have hesitated to plant rhododendrons. Happily the belief in the necessity of peat as a rooting medium is no longer general; but one now and again hears rhododendrons described as expensive. They of course cost more than a common laurel, an aucuba or a green-leaved holly, but to regard them as costly is an error not easy to understand. If we turn to the catalogues of firms who devote considerable attention to these and other evergreens we find that strong plants may be purchased at prices ranging from 3s. 6d. to 5s. each. Supposing we take the higher price, which is for good bushes that will mostly be furnished with flower buds, it will be seen that the cost will be £3 per doz., and as twenty-four plants will be sufficient for a bed of considerable size, the outlay need not be excessive in furnishing the garden with rhododendrons. Purchased by the hundred the price would be somewhat less. A smaller size may be obtained at a proportionately lower rate, but there is an objection to them when required for beds occupying a prominent position in the garden; they require two years or more before appreciably increasing in size, and when annuals are sown in the intervening spaces to hide the soil and give brightness to the bed, the rhododendrons suffer more or less. It is better from all points of view to extend the furnishing of the garden with these shrubs over two or three years, and plant strong bushes, than to fill the whole of the beds to be devoted to them in one season with plants of small size.



RHODODENDRON ROSA MUNDI.
A dwarf-growing variety, producing in great profusion rather large trusses of flowers, which are white suffused with rose, and produced in April. The plants in the fine bed at Kew herewith depicted are about twenty years old.

The preparation of the soil for rhododendrons, whether they are to be grown in beds, arranged in groups, or to occupy prominent positions as single specimens, is by no means a difficult matter. It has been already stated that peat is not essential to their successful culture, but as they flourish in it, any supplies of peat that may be available within a short distance of the garden, and obtainable at a cheap rate, should be taken advantage of. This, however, is seldom the case, and we may at once pass on to the consideration of the best method of preparing what for convenience may be described as ordinary garden soil. Rhododendrons will grow in all classes of soil provided it is free from lime, but they thrive best in one that is fairly substantial and sufficiently open to admit of the delicate roots running freely through it. Fibrous loam, to which a liberal addition of leaf-mould has been made, forms an excellent compost, and where the soil is fairly good it will suffice to take out the bottom spit and replace with the mixture of loam and leaf-mould and well incorporate it with the top spit. Should, on the other hand, the staple be a strong clay or light sand, the best course will be to take out the soil to a depth of eighteen inches or two feet and replace with the fresh compost. Planted in beds so prepared the rhododendrons will soon commence to make vigorous growth and require but little attention for several years. The distance at which the plants should be put must be determined by their size. They should be far enough apart to allow, as nearly as may be estimated, for three years' growth without their becoming unduly crowded, and when they have filled the whole bed they should be lifted and replanted, and in the latter process they should, of course, be given increased space. The surplus plants will, of course, be utilised in filling other beds and forming new groups, or planting singly on the lawn.

In the general management of rhododendrons it should be remembered that they are moisture-loving subjects, and that a little assistance, such as the watering-pot or hose can render, should be given if the weather is at all dry when they are making their new growth. An occasional overhead watering during the period in which growth is being made will also be beneficial, the evening being the best time. As the roots are near the surface it will be a further advantage to check evaporation during the summer months, and there is nothing better for the purpose than a mixture of decayed vegetable matter and cow manure in equal proportions.

The selection of varieties need not be large, but the number of fine forms is so large that it is not easy to make a small one. The following are all of a high order of merit. Alexander Adie, deep crimson; Altaclarense, rich scarlet; Barclayanum, crimson; Broughtoni, deep rose; Charles Noble, bright scarlet; Comte de Gomer, light rose with deeper margin; Everestianum, rose-lilac; Rosa Mundi, white, suffused with rose, dwarf and free flowering; it is also very early, being in full bloom on the 20th inst.; Helen Waterer, white, margined with crimson; James Nasmyth, rose tinted lilac; James Marshall Brooks, deep scarlet; John Walter, clear scarlet; Joseph Whitworth, rose-red; Lady Eleanor Cathcart, rose-crimson; Madame Carvalho, white; Michael Waterer, crimson; Mrs. John Clutton, white; Mrs. J. Penn, salmon-pink; Mrs. R. G. Holford, salmon-red; Pink Pearl, soft bright pink, very fine; Prince Arthur, claret colour; Queen of Whites, white; The Bride, white; Vestitum coccineum, rich claret; and William Austin, bright crimson.

G.

THE CHERRY STEM BORER.

As the cherry stem borer (Semasia Woeberiana) appears to be on the increase in this country, the following contribution to the current issue of the "Journal" of the Board of Agriculture by Mr. Walter E. Collinge, M.Sc., F.L.S., F.E.S., is especially deserving of the attention of fruit growers, more particularly those in cherry growing districts.

During the early part of 1908 my attention was drawn to the damage occasioned to cherry trees in various parts of Kent by the larvæ of a small moth commonly known as the Cherry Stem Borer, and later to similar damage to cherry trees in Hertfordshire. The pest increased during 1909 and 1910, and as the known remedial measures have only proved partially successful, various experiments have been made, an account of which is now given.

This insect has long been known to economic entomologists. Kollar* gave an account of it in 1837; it is also mentioned by Taschenberg,† Stainton,‡ Kaltenbach,§ and other writers. Wilkinson || records it from the Edinburgh and Belfast districts, and Theobald mentioned it in 1897,¶ in his annual reports for 1906, 1907, and 1908, and again in his work on Fruit Tree pests.** I have failed to find any reference to it in the writings of Westwood, Curtis, Whitehead, or Ormerod.

I am informed that it has been seen in past years in some parts of Worcestershire, but I have no personal knowledge of it beyond its occurrence in the two counties mentioned above.

Trees Attacked and Damage Done.

Whilst the cherry seems to be more prone to attack than other trees, this insect has also been recorded as attacking almond, apple, laurel, nectarine, peach, and plum trees.

The damage done consists of borings made through the bark into the sapwood. Often these are very small, but when a tree is badly attacked large cavities are formed, two to four inches in depth, and about the same width, extending from about one to three feet in length. Trees so infested are frequently attacked by fungi, the lower part of the stem quickly rotting, and finally dying

Life History and Habits.

The moths of the first brood appear in May and June, and the females deposit their eggs in crevices or cracks in the bark, usually close to the ground. In one case where two main roots were partially exposed it was noticed that all the eggs were deposited at the junction between stem and root. I am not able definitely to state the number of eggs; they are not all deposited together, but in isolated groups. From observations made during the past three years it would seem that they are not particularly numerous. They hatch in from five to seven days.

Immediately on hatching the larvæ commence to feed upon the bark, tunnelling beneath it, and forming irregular cavities by eating the inner bark and sapwood, sometimes penetrating as deep as three to four inches. Their presence can be easily detected by the holes made for extruding the frass. Exudations of gum are also noticeable on the trees, and not unfrequently fungi attack the exposed portions of the roots and stems.

The larvæ become full fed about the middle or end of August, and pupate on the walls of the cavities. The full fed larvæ measure slightly more than half an inch in length, and are usually of a pinkish-white or fleshy colour; occasionally they are found of a creamy-white colour, or even very pale brown. The moths appear in about fourteen days. About the time the moth is ready to emerge the pupa pushes its way through the bark. The pupa, which is enclosed in a cocoon, is deep brown in colour.

The eggs from this brood are laid in September, and the larvæ live beneath the bark until the following spring. They continue to feed until the end of October, and commence again at the end of March or early in April.

Preventive and Remedial Measures.

Theobald mentions amongst preventive measures smearing the trunks with grease and paraffin, cow dung or clay and lime, and thickly coating the stems with pitch. Brushing or painting with arsenate of lead and clay has not been found effective.

My own experiments were designed with a threefold object, viz., (i.) to make the surface of the stem obnoxious to the moths in order to prevent egg laying; (ii.) to prevent the newly hatched larvæ from boring into the bark; and (iii.) to destroy the larvæ in the cavities beneath the bark.

(i.) Various substances have been tried upon the surface of the bark, e.g., grease and paraffin, bone oil and paraffin, etc., none of which, however, were more than partially successful.

(ii.) Two experiments were made with a view to prevent the newly hatched larvæ from entering the bark. In one case the lower part of the stem was covered with pitch and gave very fair results, whilst in a second case the pitch was mixed with slaked lime, the two well worked together, and then applied to the lower part of the stem with a stiff brush. Before drying the whole of the surface was well dusted with lime. This proved most successful, no larvæ entering the bark. Kollar (op. cit., p. 237) mentions that egg laying may be prevented and the caterpillars prevented from entering the inner bark if the trees are washed about the end of May, and again in September, with a solution of lime.

(iii.) Where the larvæ were known to be in the bark a mixture consisting of one part of powdered napthalene and three parts of clay were mixed together with water to the consistency of a paste, and the trees were smeared over to a height of between two and three feet. This mixture was applied to the trees in June, and again in November. In the latter case the larvæ were particularly numerous, but no further trouble was noticed after the mixture was applied. Any composition which will adhere to the tree and make the surface obnoxious to the moths will in all probability prevent egg laying.

In the case of the trees I saw in Kent many had had the tunnels cut open and the larvæ destroyed by hand, but this constant cutting into the bark and sapwood undoubtedly injures the trees, apart from disfiguring them and leaving crevices for any stray moths to lay their eggs in.

The methods described above are both cheap and effective, and may prove of service to fruit growers who are troubled with this undesirable pest.

[illegible]

Garrya elliptica.—Among shrubs remarkable for the beauty of their long pendulous catkins, this native of California merits a prominent position. Whereas nearly all the others are deciduous, this is strictly an evergreen, the leaves being elliptical in shape, and from 1½ to 2½ inches long. The catkins, which are, as a rule, at their best during the late winter and early spring months, are in good examples quite six inches in length, and yellowish-green in colour. When well furnished with catkins, sprays of this garrya in a cut state are very effective for indoor decoration. As with many Californian shrubs, Garrya elliptica is none too hardy in some parts of the country. For this reason it is sometimes trained to a wall, but in the southern counties it can be grown as an open bush. In the case of the garrya male and female blossoms are borne on different plants, the female, which is far less showy than its mate, being seldom met with. —W. T.

CHOICE HOLLIES IN ENGLISH NURSERIES.

Shapely, well-grown hollies are not only beautiful, but are of considerable intrinsic value, and, in fact, rank amongst the most valuable stocks any nursery can hold. Being of slow growth and development, and demanding skilful attention during the younger stages, there is little risk of the market being glutted, at any rate so far as the choicer varieties or well-developed specimens are concerned. Firms who grow hollies well have usually to meet a good demand for both young plants and larger specimens. In the course of my visits to important nurseries in various parts of the kingdom, I have had the pleasure of seeing some exceedingly fine batches of the more popular kinds, and many beautiful varieties that may be classed as uncommon or rare.

In the extensive nurseries of Messrs. Dicksons, Lim., Chester, may be seen immense stretches of the ever-useful Hodginsi, one big batch numbering many thousands of plants of wonderfully even size, the average being about 3½ft. in height by as much in diameter. In another quarter were well-furnished pyramids 8ft. to 10ft. high. Silver Queen and Golden Queen, two of the finest of the variegated hollies, are largely grown, and both the green and variegated forms of the Hedgehog Holly (Ilex aquifolium ferox) are here in abundance. Such uncommon species and varieties as I. dipyrena, I. crassifolia, I. contorta, I. tortuosa, and I. brevifolia aureo picta are included in this highly interesting collection, which numbers in all somewhere between sixty and seventy distinct sorts.

Another huge stock of hollies may be seen at Messrs. James Smith and Sons, Darley Dale Nurseries, near Matlock. Young plants varying from 1ft. to 3ft. in height are grown by acres, and on the open Derbyshire hillsides the growth made is hard and sturdy indeed. Tall pyramids and massive bushes may be had in almost any known variety, whilst for hedging purposes the stock of the common holly (Ilex aquifolium) is equal to all demands.

For many years Mr. H. Frettingham, Beeston Nurseries, Notts, has made a great feature of hollies, the Beeston hollies being largely drawn upon by nurserymen and landscape gardeners throughout the kingdom. The varieties grown here are chiefly of such popular forms as I. Hodginsi, I. a. aureo marginatum, argentea marginata, Golden Queen, etc., the aim being to meet large demands for general planting.

In the Staffordshire Nurseries of Messrs. Isaac Matthews and Sons, Lim., Milton, Stoke-on-Trent, a review of which was published in the Gardeners' Magazine last autumn, I have seen superb specimens of such good things as I. laurifolia, I. tortuosa, I. Lawsoniana, the bronze-leaved holly, and I. aquifolium fructo lutea, the yellow-berried holly. Beautiful bushy plants of I. maderensis nigra up to 8ft. and 10ft. in height thrive here, in spite of the pottery chimneys that abound in the district. I. maderensis seems to be particularly well suited for growing in towns or smoky situations, and Messrs. Matthews' nurseries are well placed to meet the demands of that large district known as "The Black Country."

Near London there are several nurseries where hollies are grown extensively, and with much success. Messrs. W. Paul and Son, Waltham Cross, have for very many years made a feature of choice varieties, and magnificent specimens may be seen in these always interesting nurseries. The stock of young plants is remarkable for health, vigour, and good roots, as a result of expert management.

Messrs. Paul and Son, The Old Nurseries, Cheshunt, are also great specialists in hollies. Their High Beech nursery is famous for the quality of the stock produced on its mellow loamy soil, and it is worth anybody's while to see the fine breadths of gold, silver, and green hollies, ranging in size from young seedlings and grafts to specimens 8ft. to 10ft. in height.

At Woking Mr. Anthony Waterer's stock demands attention. The Knaphill Nursery is far famed for many things, and I have at various times been interested in the grand displays of flowering shrubs, the unique collection of topiary specimens, the noble conifers, and the hollies, of which not only an abundance of saleable stuff, but many great trees that are now to be reckoned among the permanent features of the nursery are to be seen. Naturally, the beautiful variety named Watereri is well represented in its original home, and it must be admitted that this is a holly worthy its honoured name.

At Bagshot we find hollies almost, if not quite, as important a feature as the world-famed rhododendrons inseparably associated with the firm of Messrs. John Waterer and Sons, Lim. The range of varieties here grown is remarkable, and, did space permit, I should delight in enlarging upon the quite uncommon and very beautiful sorts to be seen in these nurseries. Visitors to the leading shows are familiar with the beautiful specimens exhibited by Messrs. Waterer, and to every gardener I would say, take the first opportunity of seeing this, and, indeed, any of the collections of hollies that I have mentioned growing at home, for it is out of the ordinary run to meet with large stocks of really good hollies that have been grown with such skill and care that, whilst developing into tall shapely specimens, the root system has been so kept within bounds that the trees may be transplanted with confidence.

L. I. Atris.

VARIEGATED EVERGREEN SHRUBS.

For a garden to present a pleasing appearance at all seasons of the year nothing is more desirable than an assortment of choice evergreens, and amongst them variegated kinds should be largely planted. Their bright and showy foliage will do much to render the garden cheerful at a time when there is little to brighten the surroundings. The present is a good time to plant evergreens, and in doing this it is well to arrange them in groups where they are placed in the shrubberies, planting those belonging to the same class together, those with variegated leaves being given conspicuous positions, and so placed that they are set off by a background of green.

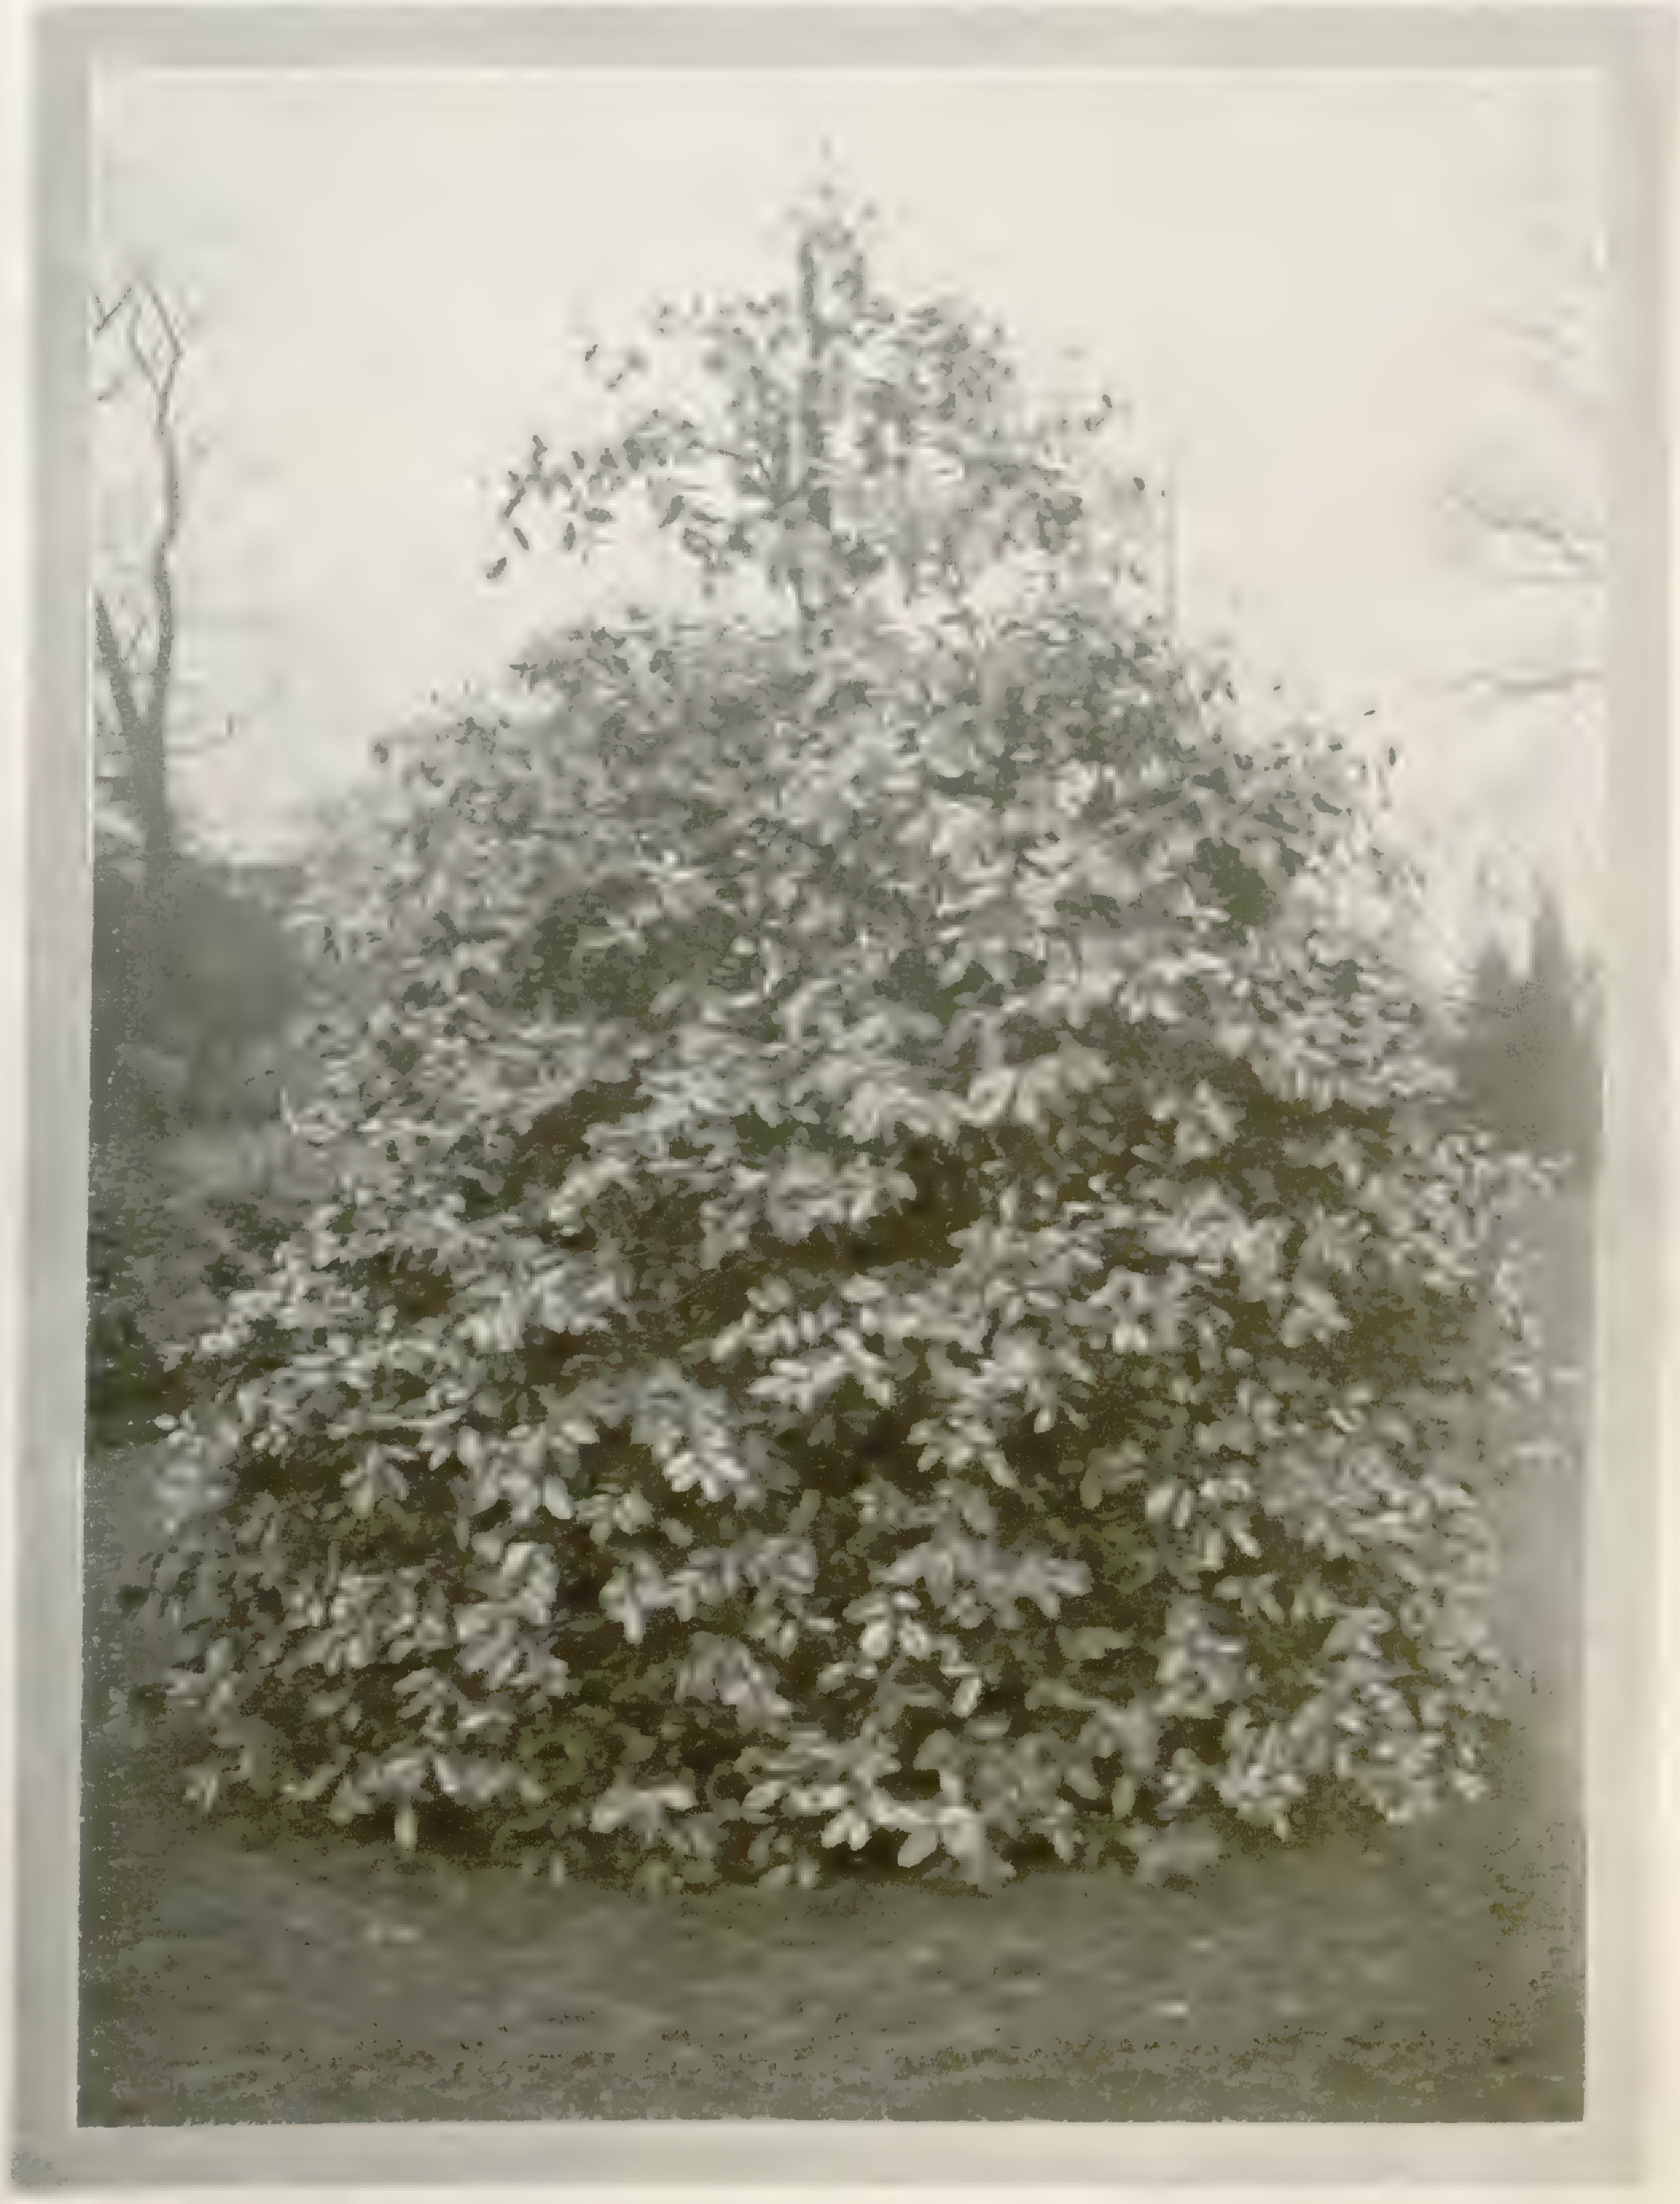
In planting it is most important to take out a hole large enough to spread out the roots fully without any of them being cramped because of too small a space. When transplanting large specimens it is important to lift them with a ball of soil about the roots, so that they may receive as little check as possible. If the soil is at all dry at the time of planting, a liberal watering will do much to give them a good start in their new positions. Another point to be taken into consideration is to allow sufficient space for each specimen to develop its natural habit of growth. This is important, because overcrowding will deprive them of their individual charm, and later on spoil their shape as specimens.

The variegated hollies are some of the most showy evergreens, and these are well adapted for planting as single specimens on the lawn, their habit of growth and rich colouring rendering them objects of unusual beauty at all seasons. Ilex ferox argentea, I. ferox aurea, and Silver Queen and Golden Queen are some of the best varieties. Weeping hollies with variegated leaves, specially when grown as standards, are very handsome, and need to be given a position where they can display their charms to advantage.

Several of the Elæagnus are very striking, and E. pungens aureo-variegata, which is shown in the accompanying illustration, is especially rich in colouring. Euonymus japonicus albo-marginatus is an effective shrub, and E. j. aurea marginata is a very showy variety. Ligustrum ovalifolium aureum is a well-known golden privet, which is always effective, and is well adapted for forming hedges. Aucuba japonica is an old but handsome variegated shrub, and is most suitable for town and seaside planting, being especially hardy. Buxus sempervirens aureo-marginata and B. argenteo-marginata are all showy. Rhamnus folio-argentea is a handsome buckthorn, which can be included where a large number of shrubs are planted. Veronica selaginoides is a lovely golden species of dwarf habit, quite a charming plant for the rock garden.

Amongst the conifers are some really handsome variegated trees, which produce rich colour effects. One of the most showy of these is Cupressus Lawsonia lutea, and several specimens of this fine variety arranged in a group produce a very fine effect. C. macrocarpa lutea is hardly less rich in colour, and looks well associated with dwarfer species, its tall pyramidal form standing out with fine effect. Thuja occidentalis lutea is also a very striking variety. Retinospora plumosa aurea is distinct and highly effective. Taxus baccata elegantissima and T. baccata aurea are lovely yews, while Taxus fastigiata aurea variegata is a very handsome form of the Irish yew, Cephalotaxus drupacea is a Chinese yew, which, on account of its bright golden foliage is quite an acquisition. Biota orientalis aurea is a handsome plant well adapted for the outskirts of shrubberies. It is also useful for seaside planting, and is invariably much admired. Juniperus chinensis aurea, J. japonica alba variegata, and Abies Sieboldiana are very effective specimens; while A. pungens glauca, A. lasiocarpa, and Cedrus atlantica glauca are all handsome trees, but on account of their large size are only recommended for extensive gardens.

J. Gardner.



ELÆAGNUS PUNGENS AUREO-VARIEGATA.
A richly-coloured variety of this handsome shrub.

Crowea saligna.—A delightful hard-wooded plant, which apart from its beauty is valuable from the fact that it will flower during the autumn and winter months. It forms a freely-branched little bush, whose slender shoots are clothed with willow-like leaves. From the axils of these the flowers are produced. They are over an inch in diameter, and of a pleasing shade of clear pink. This crowea, which is also known by the name of Crowea latifolia, is an old plant in gardens, and recent signs point to the fact that it is likely to regain its one-time popularity. A second species with narrower leaves and petals blooms as a rule in the spring. Both of these succeed under the same conditions as the more easily cultivated of the greenhouse heaths.—W. T.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

ODONTOGLOSSUM SEEDLINGS. — Any seedlings left on the pots from last year's seed beds that are ready for transplanting should now be attended to. Where only a few seedlings are grown I would suggest that the sooner they are potted off separately the better the progress they are likely to make. There is also another reason why seedlings should be treated individually at the earliest possible moment, and that is, their requirements can be properly attended to. Moreover, where the destructive maggot attacks the plants or small slugs become troublesome, we can the more readily protect the plants from injury. I also consider that after the third leaf has been developed the plants root more freely, and considerably more progress is made where the plants are treated liberally. It is advisable to see that the potting compost used is of a good and lasting nature. The sphagnum moss in particular should be only sparingly used and chopped very fine, so that there is little risk of the young plants becoming buried in sphagnum moss, immediately it begins to grow. See also that the pots and drainage are clean, and the latter ample. If bracken fern roots are used, have them thoroughly dried and freed from all sappy matter, or they will assuredly set up fungoid growth.

SEEDLING PLANTS that were put into small pots in the autumn will now need attention, and those that have made good progress will be benefited by being given more root room. It is not desirable when potting on seedlings of odontoglossums and allied genera to disturb the roots unnecessarily. If the potting compost is in a good state of preservation, carefully turn the plants out of their pots and transfer to suitable sizes without disturbing the roots. It is really surprising the progress in growth made by seedlings after the third leaf has been developed, and, if encouraged by suitable treatment after this period, it will be found that a more satisfactory first pseudo-bulb will be produced and the plants flower earlier. As the plants increase in size the compost used should be of a coarser nature, until they reach a stage when they may be expected to flower. Subsequently the ordinary compost used for the potting of the imported and other odontoglossums may be used. We find it advisable to carefully shade all fresh-potted plants from strong light, and also to give a gentle spraying at least once a day.—H. F. Chapman, Oakwood Gardens.

STOVE PLANTS.

DIEFFENBACHIAS.—These fine foliage ornamental plants are of easy culture and most attractive; under favourable treatment the plants will attain a serviceable size very rapidly. Old unsightly plants may be utilised for the propagation of new stock. After the top has been inserted as a cutting the stems may be divided into lengths, retaining a bud or two on each piece. These may be put in shallow pans or boxes and plunged in a brisk hotbed where they will quickly form roots, and may afterwards be potted up singly, using a sandy compost. It is always advisable to raise one's stock annually, as the young plants quickly develop into a useful decorative size, and when grown with single stems they are most effective.

ACALYPHAS.—For introducing colour into a group of foliage plants there is no stove plant more satisfactory that A. Macafeana, for its handsome crimson foliage gives a marked effect. Plants may be raised from cuttings rooted some time during the spring or autumn; it is perhaps advisable where space is available to insert the cuttings singly into small 60's, and plunge the latter in a moderate hotbed, keeping the propagating case closed for a few days, after which ventilation may be given carefully until root action has commenced. The plants may then be transferred to a light airy position in the intermediate stove, and eventually hardened off to full exposure of the sunlight, and placed as near the glass as circumstances permit.

ACALYPHA HISPIDA (SANDERIANA), when seen under good culture, has much to recommend it to a place in every collection, and similar treatment to A. Macfeeana may be given to it. The tails must be kept dry or they will not retain that handsome scarlet colour for long, and eventually decay from excessive moisture in the atmosphere.

ARALIA ELEGANTISSIMA is most useful for table decoration, and has a most effective and graceful appearance. Where larger specimens of the same type are desired A. Veitchi and A. gracillima will be found most valuable; they succeed best in the intermediate stove, and should be kept regularly sponged with insecticide. This will add much to their appearance, and the bottom foliage will keep in a healthy condition for a long time. When repotting aralias care must be exercised that they are not overpotted, as they succeed best with a moderate amount of rooting space, and are better adapted for decoration in smaller pots.

PANDANUS VEITCHI is an excellent plant; its white variegated foliage is much appreciated when in a small stage, and in addition it does not suffer ill effects from dryness when used for decoration indoors.—John Donoghue, Bardon Hill Gardens.

THE FLOWER GARDEN.

ANTIRRHINUMS.—Where these are intended for bedding purposes good culture must be given to ensure good-sized plants which will flower simultaneously with begonias, geraniums, etc. Assuming the beds they are to occupy are planted with spring flowers, it will be some time before they can be put out, therefore something must be done to maintain them in a progressive state. A good plan is to transfer them from the boxes to the frames which have been cleared of violets. Here every attention can be given them, and fine plants will be produced by the time they are required for bedding. This may appear too much attention for a common snapdragon, yet one is amply repaid, and, after all, the labour is small as compared with that which has to be expended on pelargoniums, and a good bed of antirrhinums is quite equal to one of the best arrangements of pelargoniums.

ANNUALS, HARDY.—On no account must the thinning of these be neglected, for if the seedlings are allowed to become drawn and leggy the results will be poor. Many of the failures with hardy annuals may be traced to overcrowding. They must have sufficient room to develop properly. Such subjects as cornflowers, Shirley poppies, and others with similar habits of growth, should have at least eighteen inches clear space to attain their full development, and, when given this, quite good-sized bushes are obtained. Clarkias, godetias, annual chrysanthemums, etc., which are not so tall-growing as the former, may have less room. The thinning operations should be gradually accomplished, extending the work over two or three intervals until the required space is obtained.

DAHLIAS.—No time must be lost in preparing the soil of beds and borders in which it is intended to plant dahlias. The exact spots should be marked off, and a stake put in. Holes about eighteen inches wide and of the same depth should be taken out, and refilled by adding a liberal quantity of well-decayed manure with the soil. This should be allowed to settle naturally without treading, and if the work is done now, the soil will be in good condition by planting time.

ROSES require considerable attention just as the buds are showing leafage. It is at this stage of growth when so much damage is caused by aphides, which increase so rapidly if allowed to remain undisturbed. Spraying with quassia extract is usually effective when persevered with, and the operation should be performed either on dull days or when the sun has lost its power in the afternoon. A sharp watch must be maintained for leaf curl, and where found the affected leaves should be pinched out with the finger and thumb.—E. C. Pooley, Gnaton Gardens.

FRUITS UNDER GLASS.

MELONS.—The earliest fruits that are advancing towards maturity should be fully exposed to all available sunshine, and a little more air be admitted when possible. These fruits require careful attention in the matter of watering to avoid giving too much or too little. Supplies of liquid manure should be stopped as soon as the fruits begin to colour. It is not well to cease watering altogether, as the fruits that are later suffer. Enough moisture must always be retained to ensure the completion of the ripening process. The plants that are being grown for producing the second crop should be kept daily tied to the wire, and as soon as enough flowers are opened they should be pollinated.

MUSCAT OF ALEXANDRIA GRAPE.—Continue to tie down and remove all laterals that are not required. Overcrowding the foliage must be avoided, and as soon as the flowers are expanding increase the temperature to 75 deg. At present keep the paths and walls nicely damped down, and at the blooming time a little drier atmosphere should be maintained. I am a firm believer in setting the grapes with the aid of a fine spray from the syringe, and when the vines are in really good health there is no better method. See that the roots are not suffering from an insufficiency of moisture. In narrow borders the roots will have so well filled them that the vines will take a surprising amount of water.

EARLY VINES.—Where the grapes are approaching or commencing the stoning period maintain an equable temperature, as the development of the fruits is proceeding slowly, and therefore it is a good plan to avoid excitement by fluctuating temperatures. As soon as it is seen that the fruits are commencing their last swelling, a good watering is, as a general rule, requisite.

FIGS (EARLY). Give these copious supplies of diluted liquid manure, and admit plenty of air on all sunny days, and shut up with copious syringings. Attend to the stopping and tying in of young shoots, giving plenty of room to shoots with the second crop, and as the fruits are reaching maturity give more air.

FIGS IN COOL HOUSES should be promptly disbudded, leaving no more growths than is absolutely necessary. It is always best to take these off before overcrowding takes place, as wood and fruits may both suffer.

PEACHES AND NECTARINES. — The early house must now be kept warm and free from great variations of temperature while the process of stoning is being carried on; but see that the roots, especially those in close proximity to the pipes, do not become dry, or this will cause the fruits to drop. Take off the surplus fruits from heavily-laden trees in the second house, and keep the growths neatly tied in. Late houses should be fumigated and disbudded as early as possible, and kept cool by giving abundance of air.

ORCHARD HOUSE.—Give liberal supplies of air on all fine days, and shut up with sunheat. Trees growing on raised beds should have copious supplies of liquid when necessary. Well-drained borders will require a good watering every other week, and care should be taken that the water reaches the soil about the roots.—W. A. Cook, Leonardslee Gardens.

For pretty gardens and lovely flowers read The Flower Garden, by T. W. Sanders, F.L.S. An up-to-date work on the formation, planting, and management of the garden, with description and cultivation of flowers and plants adapted for outdoor culture. Price 7s. 6d. net, by post, in box, 8s., from W. H. and L. Collingridge, 148 and 149, Aldersgate street, London.

ROYAL SHOW

NORWICH,
June 26th to 30th, 1911.

President—HIS MAJESTY THE KING.

72nd ANNUAL EXHIBITION of Horses, Cattle, Sheep, Pigs, Poultry and Farm Produce; Jumping, Horse-Shoeing and Butter-Making Competitions, Agricultural Education, Forestry and Horticulture.

HORTICULTURE

ENTRIES CLOSE MAY 31st.
(Live Stock Entries Close May 20th).

Prize-sheets and Entry Forms will be forwarded on application to

THOMAS McROW, Secretary.
Royal Agricultural Society of England,
16, Bedford Square, W.C.

PRELIMINARY ANNOUNCEMENT.

A GREAT SWEET PEA SHOW will be held, under the auspices of the Eastbourne Horticultural Society and the Chairman and Directors of the Devonshire Park Company, in

THE FLORAL HALL, DEVONSHIRE PARK, EASTBOURNE,

On WEDNESDAY and THURSDAY, July 19th and 20th, 1911.

ATTRACTIVE PRIZE LIST.

Special Classes for Ladies and the Trade.

Schedules for particulars of the Show may be obtained from Mr. C. R. AUST, Honorary Secretary, 5, Cornfield Road, Eastbourne.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

National Auricula and Primula Society.

The National Auricula and Primula Society held its annual exhibition at Vincent Square on Tuesday, the entire show occupying four tables in the hall. The premier class for twenty-four show varieties found Mr. Jas. Douglas, Great Bookham, once more in the front rank with fine, well-finished flowers of Heatherbell, Queen of Spain, Mikado, Favourite, Mrs. Harry Veitch, Wheatear, Prince Charming, George Lightbody, Rachel, Marmion, Victor, and Acme. Mr. W. B. Cranfield, Enfield Chase, was second with nice examples of George Rudd, Olympus, Heatherbell, Mrs. Phillips, Sunshine, Abbe Liszt, and Lapwing. Messrs. Phillips and Taylor, Bracknell, were third; and Mr. W. M. Shipman, Altrincham, fourth.

There were four competitors for twelve show varieties, Mr. Jas. Douglas leading off with a superb dozen. His varieties were: Mikado, Rachel, Favourite, Shirley Hibberd, Queen of Spain, Conservative, Harrison Weir, George Lightbody, Abbe Liszt, Marmion, Eucharis, and Wm. Smith. Messrs. Phillips and Taylor was second with excellent examples of Heatherbell, Shirley Hibberd, Geo. Rudd, and Mrs. Henwood; Mr. W. B. Cranfield was third.

In the class for six plants Mr. J. L. Gibson, Leatherhead, won well with nice level plants. The varieties were Favourite, Shirley Hibberd, Prince Charming, and George Lightbody, of the best type. Mr. W. H. Parton, Hollywood, Birmingham, was a capital second, though some of the flowers gave evidence of rapid development. Mr. F. W. Price, Beckenham, was third; and Mr. J. T. Bennett-Poe, 29, Ashley Place, was fourth.

For four plants of show varieties Mr. F. W. Price led off with really good specimens of Mrs. Henwood, Olympus, Richard Headley and Acme. Mr. W. H. Parton was second, and Mr. J. T. Bennet Poe third. There were but five entries for a single plant in the green-edged section. Mr. Jas. Douglas was first with a fine plant of Prince Charming. Mr. Shipman was second with Miss Ethel; the same exhibitor was third with the same variety.

The best grey-edged variety was Acme, from Mr. Jas. Douglas; Mr. Shipman was second with the same variety; while the same exhibitor was third. Mr. Jas. Douglas again scored in the selfs with Harrison Weir; Mr. J. T. Bennett-Poe was second with a charming plant of Mikado; Mr. W. H. Parton third with Harrison Weir.

In class nine for a pair of selfs, Mr. H. R. Taylor, Cheam, was first; Mr. J. L. Gibson being second with Capella. For four plants, Mr. W. G. Langlands, Epsom, was first with nice even examples of Mikado, Favourite, and George Rudd in fine form; while Mr. C. C. Price, Brentwood was second.

Class eleven had but one entry, that of Mr. J. L. Gibson, Leatherhead, who was deservedly awarded the first prize.

For twenty-four alpine varieties Mr. Jas. Douglas was first with a superb collection. The best varieties were Prime Minister, Phyllis Douglas, Argus, Prince of Tyre, Admiration, Mrs. Douglas, Roxborough, and Commander Douglas. Messrs. Phillips and Taylor, Bracknell, were an excellent second with some very bright colours. The best varieties were Majestic, Charmer, Empire, Argus, Salome, and Ideal. Mr. W. M. Shipman was third, with weaker plants.

For twelve alpines Mr. James Douglas was also invincible; he had clean fresh examples of Ilene, Robert Bruce, Muriel, Admiration, and Argus; Messrs. Phillips and Taylor, Bracknell, were second; Mars, Stella, Daphne, and Capella were their chief varieties, while Mr. W. M. Shipman came third with excellent plants of Bluebell, Verbal, and Admiration.

There were seven entries in the class for six plants, Mr. F. W. Price being in fine form with Argus, Majestic, Phyllis Douglas, Rosy Morn, and Mrs. James Douglas; Mr. W. H. Parton was second, and Mr. W. B. Cranfield third.

Class sixteen was for four plants, and Mr. C. C. Price led off in fine style, followed by Messrs. F. W. Price and W. H. Parton in the order named.

For a single plant, gold centre, Mr. W. H. Parton was placed first with Mrs. Danks, Mr. Shipman being second with Exquisite, while the same exhibitor was third with Duke of York.

Class eighteen found Mr. J. L. Gibson, Leatherhead, first for white centres, with a fine example of Orion. Mr. F. W. Price was second with Argus, and Mr. J. Bennett Poe third with Phyllis Douglas.

For six alpines Mr. J. Dupuy, 4, Highlands Gardens, Ilford, won first prize, Mr. Shipman being second.

Mr. H. R. Taylor won first for six alpine seedlings with a very creditable lot. There were but two entries for twelve fancy varieties; and, as might be expected, Mr. James Douglas was again placed first for some fine plants of the following varieties: Soleil, Dorothy Cutts, May Day, Mrs. Gardner, Sweet Ann Page, Ashstead, Sunset, and some good seedlings. Mr. W. B. Cranfield was second with some nice examples of Belle, Flambeau, Isir, and May Day.

Sir J. T. D. Llewelyn, Bart., Swansea, won first prize for twelve primulas arranged in two baskets. The kinds shown were P. rosea, P. frondosa, P. involucrata, P. auricula, P. Foresti, P. Palmiri, P. Kewense, P. obconica, P. malacoides, P. boveana, and P. denticulata. A very fine and interesting display.

For twelve polyanthus there were but two exhibitors. Mr. F. Bostock, Springfield, Northampton, won premier place with very fine flowers. Mr. S. Mortimer, Farnham, was second with a greater variety of colours, though lacking somewhat in size. Mr. S. Mortimer won first for a single plant with a nice white form.

Mr. F. Bostock was awarded first prize for the group of primroses and polyanthus. His flowers were large, fresh, and beautifully bright. Mr. S. Mortimer was placed second with smaller flowers, but a grand strain. The polyanthus made a really fine show.

Mr. James Douglas was to the fore for six double primroses, the crimson forms being by far the best. Mr. John Crook, Camberley, Surrey, had a beautiful basket of polyanthus in art shades. Messrs. Storrie and Storrie, Glencarse, had a fine display of polyanthus well set up in moss. The colours were tastefully arranged. The strain is a very fine one.

The premier show variety was the grey-edged George Lightbody, from Mr. James Douglas. The premier alpine was Majestic from Messrs. Phillips and Taylor.

Devon Daffodil and Spring Flower Society.

The eighth annual show of the above society was opened in the Guildhall, Plymouth, on April 19, and it was certainly the best show that the society has ever held. The daffodils, both in the open and in the Devon section, were of very high quality, and the competition was very keen, many of the classes having between twelve and fourteen entries. The flowering shrubs were superb, and the fortnight that had elapsed since the show of the Cornwall Daffodil and Spring Flower Society at Truro had brought many shrubs that were then not available into full bloom. Last year the society, thinking it wise to endeavour to popularise itself in other parts of the county beside the neighbourhood of Plymouth, where the shows had always been held up to that time, arranged for its exhibition to be held at Barnstaple. This innovation certainly had the effect of adding considerably to the membership, but owing to a certain lack of support from Plymouth, the entries rather fell off, and this year the society has returned to Plymouth as the site of the show.

The class for fifteen varieties of hardwooded shrubs or climbers was the finest ever seen in Devonshire, and even compared favourably with the preceding show at Truro. There were four Cornish and two Devon entries, and to show how close the competition was, it may be stated that only six points divided the six stands, any one of which would have won in an ordinary year. In the Devon class in the same section the competition was equally keen, there being only two points between the first and second prize stands. Many of the Cornish exhibitors competed in the open daffodil classes, and Truro winners were again successful.

The following is the prize list: Twenty-four varieties of daffodils: First prize, Miss Clarice Vivian with Aragon, Beacon, Incognita, Bullfinch, Castile, Will o' the Wisp, Stonechat, Mrs. Bowley, and Wheatear, all with bright cups; Ptarmigan, Homespun, Queen Sophia, Greeneye, Madame de Graaff, and Mrs. Camm. The class for a group of daffodil seedlings not yet in commerce unfortunately did not fill, Mr. J. C. Williams, who usually sends a collection of his beautiful unnamed seedlings, not exhibiting. Nine Magni-coronati: First prize, Miss Clarice Vivian with P. R. Barr, M. J. Berkeley, Grandis, Empress, Weardale Perfection, J. B. M. Camm, Mrs. Camm, Madame de Graaff, and Lord Roberts. Nine Medio-coronati: First prize, Miss Pope with a remarkably fine stand, containing Bernardino, Sebastian, White Star, Lady Margaret Boscawen, White Queen, Strongbow, Estelle, Homespun, and

Gold Chalice. Three incomparabilis, with white perianths: First prize, Miss Pope with Bernardino, White Queen, and Lady Margaret Boscawen. Three incomparabilis with yellow perianths: First prize, Miss Clarice Vivian with Leonie, Autocrat, and Queen Sophia. Three Barri: First prize, Miss Pope with Circlet, Southern Star, and Silene. Three Leedsi: First prize, Mr. H. G. Hawker with Evangeline, Dryad, and White Lady. Three Parvi-coronati: First prize, Miss Clarice Vivian with Ptarmigan, Stonechat, and Bullfinch. Three Poeticus: First prize, Mr. H. G. Hawker with Cassandra, Almira, and Herrick. Best bloom Magni-coronati: First prize, Mr. H. G. Hawker with Mrs. H. J. Veitch; second prize, Weardale Perfection; third prize, Glory of Noordwyk. Best bloom Medio-coronati: First prize, Miss Pope with Bernardino; second and third prizes, White Lady. Best bloom Parvi-coronati: First prize, Miss Pope with Silene; second prize, Incognita; third prize, Cassandra.

In the Devon section for daffodils, the big class for fifteen varieties was won by Mrs. Soltau Symons, who also took first prizes for six Medio-coronati; for three Parvi-coronati; for best bloom of Magni-coronati; and for best bloom of Parvi-coronati. Other winners of first prizes in these classes were Mrs. Bain-Bridge, Hon. Mrs. Colborne, Mrs. Parlby, and Mr. C. Bewes.

Spring flowers, collection of twelve varieties: First prize, Mr. H. Grigg, with a stand of exceptional merit. Six bunches of anemones: First prize, Miss A. Yonge. Six bunches Anemone fulgens: First prize, Mrs. Bainbridge. Three varieties carnations: First prize, Mr. C. Bewes. There was no entry for a group of rhododendrons, as the plants have been so terribly cut by the late frosts. The Earl of Morley was the only one to send a single truss of rhododendron, and took first prize. For the finest camellia bloom, the first prize was awarded to Mr. H. Grigg for a superb blossom of Camellia reticulata, fully seven inches in diameter. For a collection of fifteen varieties of hard-wooded flowering shrubs and climbers, first prize was won by Mr. H. Grigg, who showed Clematis indivisa lobata, Ceanothus rigidus, Magnolia soulangeana, Ribes speciosus, Cerasus Watereri, Forsythia suspensa, Amelanchier canadensis, Jasminum primulinum, Prunus persica flore-pleno, Distylium racemosum, Drimys aromatica, Erica australis, Pyrus nivalis, Calceolaria violacea, and Citrus trifoliatus. As has been said the competition was so close that there were only two points between the first and second prize stands. Mr. T. B. Bolitho gained second prize with an excellent stand, in which were several rare specimens, including Viburnum rugosum, Chorizema Lowi, Acacia diffusa, and Correa bicolor; Prostanthera rotundifolia in Rev. A. Boscawen's stand, a pretty shrub with purple flowers, was given a Certificate of Merit.

The attractions of the show were much heightened by the nurserymen's exhibits. The Devon Rosery, Torquay, staged the finest display of pot roses that had ever been seen at Plymouth, many of the plants bearing large and very perfect blooms. Among the most noticeable were Madame de Watteville, A. Singer, Celia, Leonie Lamesch, Maman Cochet, White Maman Cochet, Caroline Testout, Climbing Caroline Testout, Madame Abel Chatenay, Jean Ducher, Madame Gabrielle Drevet, Ulrich Brunner, Liberty, Innocente Pirola, Mrs. John Laing, Mrs Sanford, and Climbing Captain Christy, while there were many large ramblers. This stand received a Certificate of Merit. Messrs. Robert Veitch and Son, Exeter (Certificate of Merit) had a very interesting collection of plants, including a fine set of tree carnations, gerberas in many colours, Celmisia holosericea, C. Lindsayi, and C. coriacea, Cytisus præcox, Magnolia soulangeana nigra, Acacia Drummondi, A. cordata, Callistemon salignus, Rhododendron Yodogama, Cytisus Daisy Hill (a variety of C. andreanus), Boronia megastigma, Dendromecon rigidum, Caltha polypetala, Clematis montana rosea, C. Nellie Moser, Camellia reticulata, and several ericas. Messrs. Barr and Sons (Gold Medal) had a fine show of daffodils, including Torchlight, Bernardino, Venus, Lucifer, Lolah, Crœsus, a very pretty flower with pale yellow perianth and brilliant and spreading orange cup; Socrates, Peter Barr, Bedouin, Cœur de Lion, Lady Margaret Boscawen, Red Beacon, Ibis, Eoster, Ice Peak, Great Warley, Charm, White Queen, Oracle, Crown Prince, and Diana.

The attendance was very small during the afternoon, comparing very badly with the crowds that thronged the show at Truro, and it was said that the exhibition had not been sufficiently advertised.

National Rose Society.

Tuesday was a busy day for the members of the National Rose Society, for the Council arranged at the Westminster Palace Hotel three meetings in the afternoon and a dinner in the evening, and, as they were all exceptionally well attended, it is evident their strength was not overtaxed. The first meeting was that of the Council, which assembled at two p.m. for the transaction of the ordinary business; at three p.m. the special general meeting of the members was held for the consideration of the revised rules; and two hours later the members again assembled for the purpose of taking part in the conference on roses. This meeting extended over nearly two hours, the proceedings being brought to a close within ten minutes or so before seven p.m., the hour fixed for the dinner. The Rev. J. H. Pemberton, president of the society, occupied the chair at the three meetings, and the dinner, and thus established a record in the history of the society.

The special general meeting at three p.m. was a very short one, as the whole of the alterations that had been made in the rules and bye-laws were accepted by the members without comment. The President, in opening the proceedings, explained that the Council had, as requested by the members at the annual meeting, revised the rules in such manner as to more readily admit of the infusion of new blood than was previously possible. Hitherto the practice had been for the Council to prepare a house list of officers and members of committee, and submit such list to the members, who had the power to strike out any names they might wish, and substitute others in their place. Under the new rules it would be open to members to send in nominations on or before a given date (November 1), and such names would be entered on a list that would be sent to the members. Then, if the number of names is in excess of the vacancies, they can strike out such names as they may wish and hand the lists to the scrutineers at the annual meeting. The motion that the rules and bye-laws be received and adopted was moved by Mr. C. E. Shea in a brief speech, and seconded by Dr. Williams, who had taken a leading part in the work of revision. There was no discussion, and, on the motion being put from the chair, it was unanimously adopted.

One of the larger rooms of the hotel was secured for the purpose of the conference, but the attendance was so large that some difficulty was experienced in seating the members. The President, in expressing his regret for the crowded state of the room, said the conference was of an experimental character, and, as the experiment had proved so great a success, the Council would be careful in providing a larger room. Mr Pemberton proceeded to give his address on "Roses for the Garden," and it was exactly what such address should be—plain, practical, and interesting, and was listened to with closest attention by the two or three hundred members present, and was highly applauded. Owing to the pressure on our space, it is not possible to give even a summary of the address in this issue, and we shall refer to it again in our issue of the 6th prox.

Those who took part in the discussion included Mr. H. R. Darlington, who spoke on the points of importance in garden roses; Mr. Rolt, who referred to the colours of roses; the Mayor of Colchester (Mr. Frank Cant), who mentioned the failures that often occurred through injudicious pruning; Mr. Farrow, who referred to the eradication of mildew on roses; Mr. R. E. Felton, who spoke in appreciative terms of the Pernettiana roses; Mr. Easlea, who dissented from some of Mr. Darlington's views; Mr. G. Birch, who directed attention to the desirability of preparing a calendar showing the dates of the flowering of the several classes; and Mr. G. Paul, V.M.H., who spoke appreciatively of the value of the strong growing roses for shrubbery borders.

At the close of the discussion, a hearty vote of thanks was, on the motion of Mr. George Gordon, V.M.H., seconded by Mr. J. Green, accorded the Rev. J. H. Pemberton for his address and his conduct in the chair.

There were about sixty-five present at the dinner, and the guests included a considerable number of ladies. There were but few toasts, and, as the speeches were commendably brief, a very enjoyable evening was spent. The three loyal toasts were, as a matter of course, proposed by the President, and Mr. George Paul, V.M.H., submitted the toast of "Continued Success to the National Rose Society," and this was responded to by Mr. J. T. Strange. Mr. E. Mawley, V.M.H., proposed "The Health of the President," and testified to the remarkable ability he had shown in presiding over the several meetings, and in acknowledging the compliment Mr. Pemberton observed that whatever may be said with regard to other flowers, there could be no question that the rose is the Coronation Flower.

Broughty Ferry Horticultural Association.

The ordinary monthly meeting was held in the British Restaurant on the evening of the 18th inst. Mr. James Bethel presided over an exceedingly large number of members, as well as a number of foresters and gardeners from outlying districts, who had assembled to hear Mr. William Davidson, head forester to the Earl of Dalhousie, on the Panmure estate. "Notes on Forestry" formed an admirable text, from which the lecturer delivered a most admirable scientific and practical lecture, in which every argument went to show the valuable asset timber growing in this country would prove if taken up by qualified men who thoroughly understood the scientific, as well as practical, principles of cultivation. He deplored the fact that very often plantations were made with a subservient purpose in view, viz., "The preserving of game," which was a real hardship to the higher aims of the foresters, as rabbits and hares were his worst enemy, and caused nearly as much heart-burning as a careless sportsman often did in trying to remove some of them.

In summing up the financial position, the lecturer criticised the action of the Government in dealing with the afforestation scheme, pointing out that the Government had passed over the recognised source of information, i.e., the Royal Arboricultural Society, and relied on the meagre information obtained from County Councils, the members of which could not give unbiassed evidence. Whatever influence State afforestation might have, it must be separated from unemployment in the cities. Passing on to deal with the import timber trade, and dealing statistically with current prices and those of ten to eighteen years ago, he proved conclusively that, while Memel pitch pine and other wood was becoming scarce, the prices were still going up. As a substitute for Memel our own mature Scotch fir was equally as good as the finest, but joiners did not like it simply because it was harder to work.

When dealing with planting Mr. Davidson advised the choice of young plants, and the L notch in practice when planting; also care in selecting kinds and suitable site and soil. He had no hesitation in saying that the exposed situations on the barren and rocky eminences of the East coast were greatly re-

Make your Garden a delight by using

CANARY GUANO.

There is nothing like it for producing the best possible results in the garden. For improving Lawns, increasing the size and brilliance of Flowers, and producing heavy yields of Vegetables there is no Fertilizer that has given such excellent results. Canary Guano is sold by practically all Seedsmen throughout the United Kingdom and is used all over the world. TRY IT.

sponsible for the spread of "Larch blister," which was now a dreaded plague. When lucidly explaining the principles of thinning and pruning, the lecturer minutely described these practices through the three decades of forest-making; these he referred to as the thicket, pole, and high forest stages.

In a lengthy discussion various questions were asked, and answered. The following by their remarks added considerable interest: Mr. Smith, forester at Camperdown; Mr. Campbell, forester at Strathmartine Castle; and Mr. MacRea, City Parks, Dundee; while the local gardeners, Messrs. Grant, Christeson, Slater, Bell, and Man took part in the discussion.

On the motion of Mr. D. C. Hutcheson, Mr. Davidson received quite an ovation for his eloquent address, and his information in reply to the various questions.

The exhibits consisted of one plant of Hydrangea Hortensis, growing in a four-inch pot, and carrying seven well-developed heads, and a vase of Abutilon megapotamicum and a spike of Rehmannia angulata, all from the president, whose remarks on each evoked considerable discussion and interest.

Bournemouth Gardeners' Association.

On April 18 Mr. Thomas Alexander, of Parkstone, Dorset, gave a very interesting lecture on "Insects of the Garden."

There was a very fine exhibition of hardy and greenhouse flowers in competition for the prizes offered by the society. For six vases of hardy flowers, distinct, with own foliage, grown out of doors, Mr. Tompkins, gardener to the Dowager Lady Miller, was first with a lovely collection; Mr. C. Nippard, gardener to J. J. Norton, Esq., was a close second. In the class for four vases of greenhouse flowers, distinct, with any foliage, the same exhibitors won the two chief prizes, but Mr. Nippard beat his opponent Mr Tompkins, who was a very close second. In the first prize collection there was a beautiful vase of the hybrid greenhouse rhododendron, Countess of Haddington, the flowers being large, pure, and very fragrant. Quite a large batch of new members joined the association, which is now a very strong one. Miss Rooper, an ardent supporter of the association, offered, through Mr. Reeves, the hon. treasurer, one of her framed paintings as a prize to be awarded at the end of the year to the competitor who receives the highest number of points.

In his lecture, Mr. Alexander dealt chiefly with the insects which were more the friends of the gardener than his enemies. He referred to the great family of beetles, and especially to that little friend the ladybird, which does so much good by destroying greenfly. At one time they were collected in Germany and brought to this country. Spiders were also dealt with, and Mr. Alexander said they destroyed many kinds of winged insects, from the large bluebottle fly and the mosquito to very minute insects; they were also specially useful to farmers where ground was newly-broken up, as they covered the surface with fine webs, which colud be clearly seen on dewy mornings, and in these webs the crane flies were caught, their long legs becoming entangled, when they were soon destroyed. He mentioned that he once watched a very tiny spider overcome a large crane fly by gradually encircling the legs of the latter with a fine web, hobbling it until the spider could approach the fly and kill it.

In addition to references to insects that were friends of the gardener, Mr. Alexander discussed many that were enemies, and, though they did some good, were destructive. Wasps, moths, cockchafers, and others were all described.

A good general discussion followed, and a very enjoyable evening was brought to a close by the passing of hearty votes of thanks to the lecturer and Mr. Garner, who presided.

"FINGO" Ellis's New Summer Shades. No HOT water simply add COLD water, [illegible] [illegible] [illegible] [illegible] ORIGINAL. (Advt.)

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

SCHIZANTHUSES.—C. K., Reading: In addition to the grandiflora hybrids, the tallest schizanthuses are S. pinnatus, S. retusus, S. retusus Grahami, and S. Hookeri.

FLOWERS FOR JANUARY.—C. K., Reading: We could the better help you if we knew the accommodation at your command. Forced bulbs should figure largely, and there should be perpetual carnations, the latest chrysanthemums, eupatoriums, Euphorbia jacquinæflora and Poinsettia pulcherrima. Begonia Gloire de Lorraine, B. fuchsioides, Eupatorium Weinmannianum, E. ianthinum, Coleus thyrsoideus, zonal pelargoniums, Libonia floribunda, Linum trigynum, and, if orchids are grown, there should be plenty of the cool cypripediums, numerous odontoglossums, calanthes, and Lycaste Skinneri.

FUNGUS ON LEAVES.—G. B., Dublin: The leaves are suffering from an attack of a puccinia that approximates to P. malvacearum, the hollyhock disease. Spray with Bordeaux mixture diluted so that it does not scorch the leaves. Burn badly diseased leaves and keep the plants well away from all malvaceous subjects.

DISEASED APPLE TWIGS.—R. F. M., Devon: The trees are suffering from a bad attack of the scab fungus (Fusicladium dentriticum), and unless prompt measures are at once taken the crop of fruit will be badly scabbed, and consequently of little value. Use Bordeaux mixture at half strength, and spray the trees with it just as the flower buds begin to open; spray again when the petals have fallen, and spray a third time when the fruits are about the size of large peas. If the weather should be wet during the spraying time, a fourth application twelve or fourteen days after the third may be desirable. Next winter thoroughly spray the trees with a solution of sulphate of iron. At present, prepare the Bordeaux mixture carefully, and only use it at half strength, or it will scorch the expanding leafage.

HOT WATER AS AN INSECTICIDE.—R. P., Chester: You will find that water heated to a temperature of 150 degrees Fahr. is an effective and at the same time a safe insecticide. Keep the water at this temperature, and dip the plants in it.

STAKING SWEET PEAS.—F. A. M., West Runton: We believe in staking sweet peas as soon as they are planted, as it affords the plants some protection, and they seem to know that supports are at hand for them to climb. Have you read "Sweet Peas and their Cultivation," by Mr. C. H. Curtis, hon. secretary of the National Sweet Pea Society? It gives full directions for staking and many interesting particulars concerning the use of substitutes for ordinary stakes. It can be obtained post free for 1s. 2d. from The Gardeners' Magazine Office, 148 and 149, Aldersgate Street, E.C.

POTATOES IMMUNE FROM WART DISEASE.—J. E. W., Malpas: It is doubtful whether any potato is absolutely immune from wart disease over several years, but there are varieties which have so far proved capable of resisting an attack even in a district where the disease is frequently met with. In a memorandum issued by the Board of Agriculture last month the following varieties were "recommended as having yielded on the whole good, large crops, free from wart disease". Early varieties—Midlecross Early and Aberlady Early; second early—Conquest and Sutton's Abundance; maincrop—Davies' Laird, White City, The Crofter, The Provost, Langworthy, What's Wanted, and Golden Wonder. The memorandum also states that, "In order to see whether the potatoes which were found to be disease-resistant when planted on certain farms in Lancashire, Cheshire, and Shropshire in 1909, would remain immune when planted in cottage gardens or allotments in other districes, a supply of the 'seed' potatoes of the three varieties, Conquest, Golden Wonder, and Langworthy, saved from the experiments conducted in 1909, was distributed to rather more than fifty centres in Cumberland, Lancashire, Cheshire, Staffordshire, Shropshire, Worcestershire, Warwickshire, Derbyshire, and Nottinghamshire. These potatoes were planted in badly infected soil, and with scarcely any exception proved to be disease-resistant. There is some reason to think that a few of these exceptions may have been due to 'self-set' potatoes of some other variety that had been overlooked, since in only one centre were all three varieties attacked, and in every district in which one variety was attacked, the same variety grown on a neighbouring plot was immune."

DUTCHMAN'S PIPE.—S. R. E., Letchworth: The popular title of Dutchman's Pipe has been given to the very ornamental climber known in gardens as Aristolochia sipho, and the title refers to the quaint, curved, pipe-like shape of the small and ineffective flowers. The plant is quite hardy, and a famous climber, its big, heart-shaped leaves measuring six or eight inches across. Aristolochia sipho needs no special soil, but it should have plenty of room to ramble, as it will cover a large space when established.

WATERING NEWLY-PLANTED SWEET PEAS.—S. W., Oxford: A great mistake is made in watering newly-planted sweet peas with water obtained direct from the pipes. Where possible, the water should be exposed to the air in a tub or tank for a dozen hours or more before use, and even then it will be all the better if a few gallons of hot water are added before use "to take the chill off." We believe that watering sweet peas at this season of the year with water direct from the service pipes is often responsible for a great deal of harm

DAMAGED TULIP LEAVES.—B. D. T., Shepperton: The damage done to the leaves is not due to fungus attack or to animals, but is caused by the sharp frosts and biting winds experienced two or three weeks ago. We are sorry to say we have hundreds of tulips with their leaves damaged in similar fashion, and they look as though they had been sprayed with some burning solution.

NAMES OF PLANTS.

T. L., Surrey.—Masdevallia coccinea Lindeni.

P., Purley.—Not recognised: send when in flower.

M. P. W., Exeter.—1, Cytisus præcox; 2, Rhododendron racemosum; 3, Veronica Hulkeana.

GROWN WITHOUT VAPORITE.

If your cabbages, lettuces, geraniums and other plants and vegetables have holes eaten into them by **Caterpillars**;

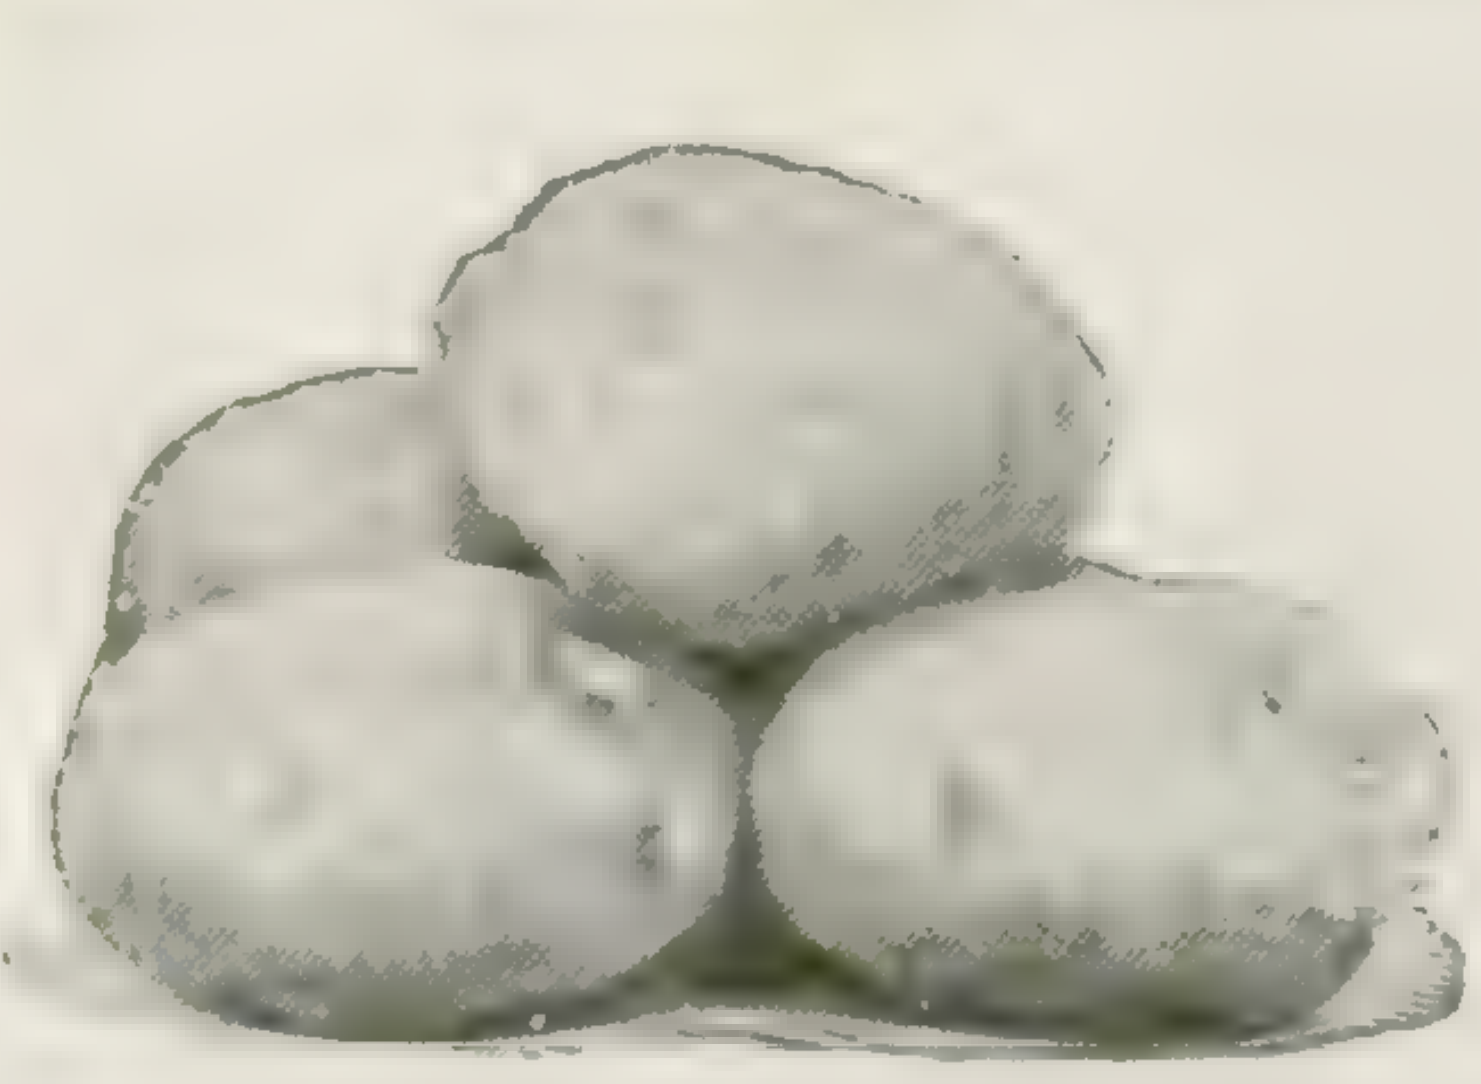
If your sweet peas are eaten off as they come up by **Slugs**;

If your potatoes, carrots, etc., are disfigured by **Wireworms**;

VAPORITE

The ORIGINAL SOIL INSECTICIDE.

will put an end to all these hungry insects.
Vaporite simply requires digging into your garden (1 lb. to 8 square yards) at the last digging before bedding out, or before planting your kitchen garden, to ensure it looking at its best in the summer.
In addition, Vaporite destroys other soil insects which are almost invisible and whose presence is often unsuspected, but all of which **live on your plants.**
By their destruction you ensure the fullest development of all your plants.
No gardener can afford to be without Vaporite in the Spring.
Every package contains full directions for use.



GROWN WITH VAPORITE.

PRICES: Tins, 1½lbs., **9d.**; 7 lbs. **2/-**; 14 lbs. **3/-**; 28 lbs. **4/6.** *Carriage [illegible]* all seedsmen. Casks: **7/6** ½ cwt.; **11/6** cwt. Carriage paid from your seedsmen or the Company.

OBITUARY.

◆

MR. J. R. TRANTER.

We regret to record the death of Mr. J. R. Tranter, which occurred suddenly at his residence at Henley on the 20th inst. Originally a builder by trade, Mr. Tranter had a strong love for flowers, his special favourite being the dahlia, which, as an amateur, he grew with much success, and about fifteen years ago he engaged in business as a nurseryman. He was a successful cultivator and exhibitor of dahlias, and raised several good varieties, notably Mrs. Tranter. Mr. Tranter was a director of the Henley Waterworks Company, and a manager of the Henley Penny Savings Bank, and he was for many years a member of the committee of the National Dahlia Society.

KELWAY'S LATEST SUCCESS.
GRAND PRIX AND GOLD MEDAL, Japan-British Exhibition, White City. Unanimous award of the International Jury to Kelway and Son for Pæonies, Delphiniums, Gladioli, Pyrethrums, etc.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

THE LIBERTY of the KELWAY GARDEN versus the Tyranny of the Bedding-out system. Infinite variety; no sameness of treatment.
ABSOLUTE FREEDOM of choice of treatment for your garden or garden borders. See "Gardens of Delight," post free, 6d.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

KELWAY'S MANUAL OF HORTICULTURE is the best of all Garden Books. 2s. post free, from KELWAY and SON, LANGPORT, SOMERSET.
TESTIMONIAL.
From ———, Esq., Guildford.
"I may say that your Illustrated Catalogue is without doubt the finest book of the sort I have had the pleasure of seeing."

NOW IS THE TIME TO PLANT KELWAY DELPHINIUMS, which have been improved almost out of recognition in the past twenty years. They produce plants ranging in height from four to eight feet, exceptionally hardy and with a rich profusion of choice blooms in all the shades of that valuable colour, blue.
Choice named varieties: 24s., 34s., and 56s. a dozen. Carriage and package free for remittance with order.
The celebrated present-day Delphiniums, and nearly all the best well-known varieties shown at exhibitions, originated in Kelway's Langport Nurseries.
TESTIMONIAL.
From Mrs. ———, Eltham, Kent, 18th April, 1911.
"The Delphiniums and Pyrethrums you sent me three years ago are doing splendidly, and were a joy last summer.

KELWAY and SON, The Royal Horticulturists, LANGPORT, SOMERSET.

NOTE OF THE WEEK.

◆

Species of Plants and Their Differentiation.

A German botanist, J. C. Th. Uphof, has recently estimated the species of known flowering plants to reach the astounding number of 133,082, and those of ferns as 4,521. Among the former the largest family appears to be that of the Compositæ, which embraces 14,324 species, while the palms have 1,085, the grasses 3,545, and the orchids no less than 7,521. Of course, it is probable that these numbers would be largely modified in both directions by botanists who are known as "lumpers" and "splitters," i.e., those who ignore small differences and class together plants as of the same species which others regard as distinct, and those who define as separate species those of any similar type which are possibly merely varieties of one and the same. Nature draws no hard and fast lines, a different environment, a different climate, will undoubtedly modify the specific types to some extent, and, what is more to the point, every now and again, and, so far as we can ascertain, without impulse of this kind, she modifies it, often very greatly by inventing, as it were, new types or "sports" or "mutations," which, while retaining the generic character, materially alters the specific one, so that, if, as is usually the case, this new type is capable of reproducing itself truly by seed or spore, it fulfils all the requirements of a new species entirely. Here, however, it is practically impossible for the classifying botanist to rank such varieties as new species. When we consider that, taking our British ferns as an example, several of the species have sported under wild conditions into hundreds of distinct varieties, and all plants, more or less, are subject to similar variation, it is obvious that their acceptance as species would involve the multiplication of the above figures by scores or many scores in order only to embrace all the different natural forms, while if cultivated ones were included their name would indeed be legion, and the ponderous volumes of the Kew list would fill a large library. The exact definition of a species is a very difficult matter for the botanist. The merely local botanist finds comparatively little difficulty in determining the species he comes across in his travels, but when the cosmopolitan botanist has recourse to his herbarium containing species from all over the world, he finds linking forms which blur the sharp dividing line which the local botanist easily finds, and "lumping" or "splitting" then occurs precisely in accordance with the proclivities of the botanists concerned. Amongst our hardy ferns, to recur to a familiar branch, we find Polystichum setosum, with its lucent ciliated fronds, is considered by some as a form of P. aculeatum, despite, to the fern student here, the clear specific difference between them. He is also greatly puzzled by the allocation of such a fern as the Lady Fern (Athyrium filix foemina) in its common form to the asplenia, and in its less common form of the Scottish mountains (Pseudathyrium alpestre), actually to the polypodiums, despite its difference in all, in his opinion, truly specific characters. With our native Blechnum spicant we have a peculiar instance of allocation by even the Kew authorities, to a wrong genus, viz., Lomaria. Fern genera are determined by the form in which the spores are borne and the peculiarities by which they are protected or unprotected, as the case may be, this feature having been found to be the most reliable and persistent, despite changes of specific type. Botanists are entirely agreed that in Blechnum the spores are borne on contracted fronds, and protected by a cover well within the margin and quite independent of it, while in Lomaria, the edge of the frond division itself is turned backward and acts as indusium or protective cover. Our native Blechnum quite clearly shows the independent indusium of its genus, and there is actually a not very rare form of it, B. s. anomalum, in which there is a wide space between the spore heaps and the margin, a form impossible to Lomaria. That has been pointed out for years, but nevertheless, it figures as Lomaria at Kew, and, as a consequence, in many books and lists. In this connection, it is a curious and unfortunate fact that it is almost impossible to get a mistake of this sort corrected, even when, as in this case, a mere glance at the plant itself cannot fail to be convincing. In Britten's "European Ferns," the difference is shown by clear drawings in the body of the book, and the plant is described under Blechnum, the coloured frontispiece, however, is labelled "Lomaria," the writer and the illustrator being obviously at variance here, as they are elsewhere in numerous cases where different synonyms are used.

MR. F. HANSON.

Mr. F. Hanson, whose portrait we give in this issue, has for many years occupied a foremost place among the practical horticulturists in East Anglia, and the high position to which he has attained may be ascribed to a rare combination of administrative ability, cultural skill, and a genial temperament. We are not quite certain as to the year in which Mr. Hanson assumed the charge of the gardens of Somerleyton Hall, the fine Suffolk seat of the Right Hon. Sir Saville Crossley, Bart., but it is nearly twenty years since we gave an illustrated account of the extensive and beautiful gardens, which at that time, as now, were regarded by all who were acquainted with them as forming one of the best-kept horticultural establishments in the county. In walking through these great gardens, in which the owner takes so keen an interest, it is not easy—if, indeed, it is possible—for the visitor to determine whether Mr. Hanson has any preference in relation to garden management, so high is the keeping in all departments. In the flower garden we find displays of hardy and tender plants of surpassing beauty, and in the kitchen garden crops that bespeak cultural skill of a high order; while under glass, from the magnificent winter garden to the smaller structures, tender plants and fruit crops are met with in the best possible condition. As an exhibitor Mr. Hanson has excelled with chrysanthemums and hardy fruits, and we have a clear recollection of the splendidly-developed blooms of chrysanthemums, and the even more noteworthy collections of apples and pears, with which he has obtained premier honours at Norwich during the past fifteen or more years.

Royal International Horticultural Exhibition, 1912.—The Lord Mayor has issued invitations for a meeting at the Mansion House for the purpose of promoting the success of the Horticultural International Exhibition, which will be held in London in May next year. The meeting will take place on May 10 at 3 p.m. in the Egyptian Hall. Amongst those who are expected to address the meeting are Lord Balfour of Burleigh, K.T., Lord Rothschild, G.C.V.O., Lord Aldenham, the Hon. Vicary Gibbs, Alderman Sir Marcus Samuel, Bart., and Sir Jeremiah Colman, Bart. The scheme for the exhibition has already the patronage of the King and Queen and Queen Alexandra.

Ornamental Cherries constitute at the present time a distinct and beautiful feature of the Royal Gardens, Kew, and those who are interested in trees remarkable for the beauty of their flowers should, if they have the opportunity, see them during the time the flowers show their true colouring. The finer kinds have been rather freely planted within recent years, and there will be no difficulty in meeting with good specimens, and the example that has been set at Kew might with advantage be followed in other great gardens. The pale pink and exceedingly beautiful Prunus pseudo-cerasus fl. pl. is the most largely represented, and the finest specimen is in the Pagoda Avenue, and this has during the past fortnight been simply a huge bouquet of flowers. Somewhat later in flowering, and surpassingly beautiful, is the rich rose-coloured P. pseudo cerasus J. H. Veitch, of which comparatively large specimens may be found in the Pagoda Avenue and near the tropical lily house, which is not far distant from the palm house. The effect produced by the wreaths of large, richly-coloured flowers is such as to at once arrest attention, and it is interesting to observe how the visitors crowd around the trees. Sometimes comparisons are instituted between the two cherries last named, with a view to determine their relative merits, but there is really no occasion to do this, as both should have a place in every garden. They are quite distinct in colour, and differ in the time of flowering by about two weeks. The yellow-flowered cherry (P. serrulata flore pleno lutea) is flowering in the most profuse manner, and the fine specimen presents a charming appearance. The flowers are not yellow, but a rich cream colour. The pure white P. avium flore pleno is also flowering freely, the finest specimens being the one near the Cumberland Mound and those in the Pagoda Avenue. The new rose-coloured P. Sargenti is now out of bloom, but the small tree in the collection has flowered freely, and given promise of being a valuable addition to the ornamental cherries. The flowers are single, and consequently are more ephemeral than those of the double varieties. Visitors to Kew should also note the rich effect produced by the groups of Berberis stenophylla.

Horticultural Club.—The next house dinner of the Horticultural Club will be held at the Hotel Windsor, Westminster, on Tuesday, May 9, to be followed by a lecture on "Glimpses of Morocco and the Canary Isles," by Mr. T. Ernest Waltham; the lecturer will wear the national costume of Morocco, and his lecture will be illustrated by a hundred lantern slides, made from photographs taken by himself. All the members of the club have now received a list of members elected up to April 30, and a list of the Club Rules, both of which they much appreciate. The new hon. sec., Mr. R. Hooper Pearson, Braewyn, Earlsfield Road, Wandsworth Common, S.W., will gladly receive nominations for membership.

Perpetual-flowering Carnations.—In our next issue we shall devote special attention to perpetual-flowering carnations. The articles will deal with cultivation and the selection of varieties, and among the illustrations will be several of the most noteworthy of the exhibits at the Perpetual-flowering Carnation Society's show,of which a report appears in this issue.

Springtime at Balmoral. Our Aberdeen correspondent writes: "The surroundings of Balmoral Castle are, with the advance of the year, daily becoming more delightful. With seasonable haste old Dame Nature is discarding her austere winter garb, which at an altitude of 1,000 feet above sea level lingers in the eye longer than in the lowlands. To the fine, moist, and genial weather experienced in the latter half of April, the face of Nature has at once responded. The grey, sterile-looking fields, having heard the "voice of spring," are, as if by magic, flourishing green again. Trees are budding vigorously, and the policies and parks have assumed the charm of true springtime; and one begins to survey the scene forgetful of the snow wreaths still clinging to the distant slopes of "Dark Lochnagar," which still maintains its wonted stubborn fight against the ever-strengthening genial breezes which herald the approach of summer. It is expected that after the Coronation and the Royal visits to Dublin and Edinburgh their Majesties will visit Balmoral in August, and make a long stay. If one would like to see Balmoral and its surroundings at their very best, August and September are the months to choose for the visit. Then the hills are purple to their summits with the "bonnie bloomin' heather," and in the valleys the fields of golden grain, with the silvery Dee winding its zigzag course along to the sea, all combine to make one of the most exquisite settings in which any Royal residence was ever placed since kings began to rule.

National Sweet Pea Society.—A special general meeting of this society will be held at the Hotel Windsor, Westminster, at 2.30 p.m., on Thursday, May 18, for the purpose of considering and adopting a set of rules for the constitution and government of the Society's Floral Committee. These rules formulated by a sub-committee and approved by the General Committee will become immediately operative, as passed at the meeting of May 18. Notice of meeting and a copy of the proposed rules have been sent to every member of the society.

Spring Flowers in Regent's Park.—The traditions of Regent's Park are worthily maintained, and at the present time there is a surprisingly beautiful display of bulbous and other spring-flowering plants. The numerous beds on the lawns that flank and divide the Chestnut Avenue in the south-east corner of the park are chiefly filled with hyacinths, tulips, and daffodils, and, as the colours have been arranged with due regard to harmony, the colour effect is at once rich and beautiful. The large beds of hyacinths are now past their best, but the huge spikes show that when in perfection they were most effective. The tulips, which include the finest of the early-flowering varieties suitable for massing, are now in their highest state of development, and produce a series of brilliant colour effects. The large bed, which is usually filled with tropical plants during the summer months, is wholly devoted to tulips, which are arranged in blocks, and form a delightful colour scheme. The opposite mound is clothed with trumpet daffodils, and on the wide lawn near Gloucester Gate there is a remarkably fine breadth of star daffodils now at the zenith of their beauty.

Bargany, Ayrshire.—Through the kindness of Mr. North Dalrymple Hamilton, of Bargany, the picturesque policies of that estate are now to be open to visitors during the summer months. A request for such permission emanated from the Girvan Town Council, and a reply to the above effect has been received by that body from Mr. Inglis, the factor on the property. Admission is to be limited to a certain number, and is to be by ticket. Mr. D. Buchanan, the gardener on the estate, is one of the best-known of Scottish gardeners, and the policies are always maintained in the highest condition. The trees and shrubs are very fine, and altogether the inhabitants of Girvan are to be congratulated on obtaining permission to visit such a fine place.

Accident at Balmoral Castle.—Alexander Smith (36), the gardener's horseman at Balmoral Castle, is suffering from a serious accident, which occurred while he was at work on the lawns at the castle last week. Smith and another man were rolling the lawns with a horse-roller, when the horse took fright at the noise of the implement, and bolted. Smith fell, and was struck with the roller. He was removed to his home, and medical assistance at once secured.

The Old Gardens of Italy were the subject of a highly interesting lecture given by Mr. Joseph Cheal the other evening before the members of the Brighton Horticultural Society. In the course of his lecture Mr. Cheal stated that the love of gardening in Italy may be traced to an early period in the history of the country, and it may be assumed the Roman Generals brought home glowing accounts of the gardens they had seen in Eastern countries. It was probable that these accounts stimulated the imagination of Lucullus and induced him to make the fine garden at Naples described by Pompey, and thus become the pioneer of the grand style of gardening that became so popular at a later date. Emperor Hadrian also did much to stimulate a taste for the higher branches of architecture and horticulture, but during the comparatively long period over which the decline of the Roman Empire extended there was a material decrease in the taste for the stately style of gardening. Towards the end of the fourteenth century there was a considerable revival in the taste for gardening, and, during the Renaissance, dignitaries of the Church and wealthy senators and merchants appear to have vied with each other in the building of houses and the construction of gardens. Certainly the arts of the architect, the sculptor, and the landscape gardener were employed in the creation of the magnificent gardens of the period. The style that found favour was more or less formal, and the gardens were embellished with terraces and parterres, fountains, and cascades, temples and cascades, and avenues and pergolas in great variety. The climate favoured the development of a wealth of trees, shrubs, and flowering plants, and these in their luxuriant growth afforded a succession of delightful pictures, and filled the air with grateful perfumes. The shady walks, avenues, and grottos provided cool retreats during the heat of spring and summer, and the rippling of the cascades, the splashing of the fountains, and the song of birds greatly enhanced the charms of these gardens. Many of the more noteworthy gardens were described and the lecture was throughout illustrated with excellent slides. Need it be said that the audience greatly appreciated the intellectual feast provided them, or that Mr. Cheal was heartily thanked for his lecture.

Royal Horticultural Society of Aberdeen. The prize schedule for the forthcoming show of this society, to be held in the Duthie Public Park, Aberdeen, in August, presents some interesting and novel features. Many and varied are the prizes offered, including several valuable challenge cups—some presented by the society, and others the gifts of patrons and well-wishers. No fewer than four valuable silver cups are to be awarded this year, besides a large number of silver medals, and over £150 in money prizes. Some years ago the directors instituted special prizes for sweet peas, a flower in which great development has taken place in recent years, and which is at its very best at the time of the show. This year specially valuable prizes have been offered for this flower, so as to render it a distinctive feature. In the classes for roses also there are additional prizes offered by patrons of the society, thus ensuring a large number of attractive exhibits, which should make the show this year, so far, at least, as sweet peas and roses are concerned, the finest ever held in the North of Scotland.

Messrs. Sutton and Sons were awarded the Silver-gilt Banksian Medal for the remarkably fine collection of spring vegetables exhibited by them at the meeting of the Royal Horticultural Society, held on April 25, and described in our issue of the 29th ult.

R.H.S. Journal. The Rev. W. Wilks, M.A., writes as follows: "The President and Council of the Royal Horticultural Society greatly regret the unavoidable delay which has taken place in the issue of the society's journal, caused by the recent strike of printers' operatives in London."

Gladioli in America. The American Gladioli Society has a membership of 172, and considers that it must depend largely for new members upon amateurs. Efforts are being made to institute a thorough trial of gladioli varieties at Ithaca, for the purpose of testing merit and correcting nomenclature. A scheme of pointing to be used in the consideration of novelties for certificates was arranged as follows: Resistance to disease, 5; texture of flower, 10; duration of bloom, 10; size of bloom, 10; colour of bloom, 15; form of flower, 10; form of spike, 10; stem (length and stiffness), 10; number of flowers on spike, 15; vigour (aside from disease resistance), 5; total, 100.

Intensive Culture is being carried out with much success on Lancashire County Council's farm at Hutton, near Preston, and some photographs that we have had an opportunity of seeing show that during the winter the frames were filled with cabbage lettuces of great excellence.

ROSES FOR THE GARDEN.

As duly recorded in our issue of the 29th ult., the National Rose Society held a conference at the Westminster Palace Hotel on the previous Tuesday, which was regarded by all who had the pleasure of being present as an unqualified success. The subject selected for consideration was "Roses for the Garden," and the discussion was opened by the President (the Rev. J. H. Pemberton), who is not less conversant with the roses for garden decoration than he is with exhibition varieties, in the cultivation of which he is so well known as a past master.

In his opening remarks Mr. Pemberton said he was delighted to see so large a gathering, for it afforded the best possible proof that a large number of the members were greatly interested in roses that are especially adapted for beautifying the garden, and the supply of blooms for the decoration of indoor apartments. He was sorry the room was crowded, but the council of the society had no data on which to base an opinion of the number of members likely to be present, and it was thought that the large room in which they were assembled would be fully equal to the requirements. He was gratified by the large number present, because it augured well for other conferences, which, he hoped, in the future would form part of the society's regular work. He believed it to be good for rosarians to confer together from time to time upon matters requiring attention in the cultivation of roses, as it was possible at such conferences to afford assistance to each other.

The subject for consideration was roses for the garden, and, as they had met for the purpose of conferring with each other, he hoped his opening address would be regarded simply as a peg on which to hang the discussion, and this he trusted would be as full as the time at disposal would permit. They were met to discuss garden roses, and not the varieties which bear flowers that render them of special value for exhibition. They had now become a great and important class, and it was satisfactory to know that the rose, while still held in the highest estimation for exhibition, was now being given the prominent position in the garden that it so well deserved. The rose, he ventured to suggest, fully justified its title as the Queen of Flowers, and was worthy of the position it occupies as the national emblem of the British Empire.

There was no occasion to refer at length to the claims which the rose has on owners of gardens, for these were now being acknowledged, as evidenced by the enormous extension of rose culture within recent years. He might point out that the rose had certainly no superior in beauty among the many plants that have now a place in the garden, and it surpassed all others in the period over which the season of flowering extends. Many of the rosarians present had in all probability read the story of the rise of the hybrid perpetuals in the Early Victorian period, and there could be little doubt of their being conversant with the fact that many of the so-called hybrid perpetuals had a comparatively short season of flowering. But the intercrossing of these with the tea-scented varieties had resulted in the creation of a race of roses that were so continuous in flowering as to render it possible to have the garden as bright with roses in September as in June.

By the inclusion of some of the early-flowering species in a selection, it is possible to have roses in the garden from April till Christmas, and as a proof of the continuous flowering of some of the varieties until the winter had commenced, Miss Pemberton had been able for several years past to place six vases of roses on the altar of his church on Christmas Day, all the blooms having been cut from plants growing in the open. The season of roses commenced with the Banksian roses, the single yellow being the earliest to bloom and was carried on by Rosa altaica, R. alpina, and other of the species that yield of their blossoms early in the summer, the teas, the hybrid teas, and other of the well-known classes.

He submitted that the rose meets all the requirements of cultivators. It is admirably adapted for the formation of hedges, screens, pillars, and specimen plants; it is of much value for clothing pergolas, for the supply of cut flowers, and also for bedding purposes. The owners of gardens were no longer tied to the various softwood plants for filling beds, as, with the aid of suitable varieties, they could have a continuous display of roses extending over a long period. The great value of roses for bedding had been proved to demonstration at the White City during the past two years. In one year Continental growers had shown what roses are capable of as bedding plants, and in the other English growers had demonstrated not less clearly the wondrous beauty of bedding roses when they are planted and grown under proper conditions.

The importance of a knowledge of the several sections was insisted upon, and Mr. Pemberton reminded those present that if they wished to excel in growing roses, they must cultivate the power of observation. There were many growers who were successful with chrysanthemums and sweet peas, but who failed in some degree with roses, and this was explained by the fact that, while the two classes of flowers first mentioned can be treated all alike, all the roses cannot be treated in the same way. Roses have different habits, and not until the points of difference are understood can success be achieved. He suggested that those who know but little about roses should go out into the fields and lanes and study the growth of the Field Rose (Rosa arvensis) and the Dog Rose (R. canina), and when they had proceeded far enough to enable them to differentiate between the growth of those two roses, they might take the pruning knife from their pocket and proceed to prune their roses. Not only was there a great difference in the habit of the various groups, but varieties in the same group differed materially, and unless this fact is recognised and acted upon, there is a risk of the cultivator, when pruning, cutting away the flowering wood. Cultivators should, indeed, know their roses so well as to be able to recognise each variety, even in the depth of winter.

In connection with pillar roses Mr. Pemberton pointed out that it was necessary to remember that there are not, as a matter of fact, any roses that are true climbers. The growth of the so-called climbers was naturally rambling, and a good name for the whole race is rambler. In the cultivation of these there is no occasion to trouble about budding and grafting, as the propagation of the multiflorus and Wichuraianas can be readily effected by means of cuttings. It is simply necessary in August to slip off the side shoots with a small heel; to trim the latter, and to shorten the shoots to six or eight inches, and remove all but the top leaves. They should be then placed in trenches four or five inches in depth with a little fine sand in the bottom, and have the soil filled in about them, and have it well trodden. It is important to make note of the wood that bears the flowers, for when this is done it is found that flowers are produced on the shoots that spring from the base, and that when they are cut back the flowers are lost. The proper course is to thin out the shoots that have flowered, and shorten the young shoots by the removal of the soft portion at the top. When the thinning-out is done early in the autumn the remaining growths will become well ripened throughout the greater part, if not the whole of the length. Many gardeners liked to trim their ramblers close back, and as the result lose their flowers. Ramblers should not be tied up closely to the posts. The shoots, as so well known to those who observe their roses closely, bend over in process of development, and the new shoots rise up in the centre. It is a good practice to stretch a moderately stout cord between the posts and secure the growths to them in a slanting direction.

(To be continued.)

PERPETUAL-FLOWERING CARNATION SOCIETY.

This society's tenth exhibition was held at the Royal Botanic Gardens, Regent's Park, on May 2 and 3. The show was a good one, but probably not quite up to the high-water mark of the previous one held at Westminster. Some of the flowers were of remarkable size and beauty, and as shown in quantity they attracted full attention and admiration. It is no wonder at all that perpetual carnations are popular. Messrs. Brunton, Mathias, and Hawes carried out the arrangements in good style, and were ably assisted by several members of the committee.

OPEN CLASSES.

The premier award and Gold Medal for a collection of carnations arranged on a space 10ft. by 3ft., was won by Messrs. Young and Co., Hatherley, Cheltenham, with a bold and fine display of good flowers of Lady Audley Nield, Mrs. Greswolde Williams, Enchantress, Mrs. Burnett, Mikado, Queen, Cheltonian, White Perfection, and the crimson Duchess of Devonshire; Mr. F. C. Harwood, Upton Leigh, Torquay, second.

First prize and the Brunton Cup for three vases of British novelties distributed since January, 1909, fell to Mr. C. Engelmann, Saffron Walden, for Regina, Carola, and Rex; Mr. W. E. Wallace, Eaton Bray, second with May Day, Delight, and Scarlet Glow; one competitor was disqualified for showing Britannia, which was sent out in 1906. The American Cup for three vases of American novelties was won by Mr. B. E. Bell, Castel, Guernsey, with Whitcombe Riley, the flaked Bay State, and Governor Duveen; he was the only competitor.

Mr. W. C. Wallace, Eaton Bray, won the Covent Garden Bowl for two varieties of carnations, sixty blooms of each, half to be packed in boxes, and half set up in vases; he showed Rose Pink Enchantress and White Enchantress in his usual fine style; the Thatcham Fruit and Flower Farm, Newbury, came second with Enchantress and Winsor. Mr. Burnett was unfortunately disqualified; a few of his flowers had wire supports.

LARGE VASES.

The open classes for twenty-five blooms of a variety were well contested. For the Enchantress set Mr. W. E. Wallace led with that variety; Mr. B. Bell second with Admiration; and Mr. H. Burnett third with Enchantress. In the Mrs. Burnett class, Mr. A. Smith, Enfield Highway, scored with Empire Day; Mr. Wallace second with May Day; and Mr. Dalton, third with May Day. For flowers of the Winsor type Mr. Wallace led with that variety in grand form; Mr. Bell second with Winsor; and Mr. Burnett third with R. F. Felton, the latter very large. In the Lawson class Mr. B. Bell was a capital first with Mrs. C. W. Ward—a grand vase; Mr. C. Engelmann second with Mrs. T. W. Lawson; and Mr. Dalton, Iver, Bucks, third with Lawson Enchantress.

For a vase of white flowers Mr. Wallace was to the fore with White Enchantress; Mr. Bell second with Judith; and the Thatcham Fruit and Flower Farm, third, with White Perfection. The best vase of a scarlet variety was Beacon, from Mr. A. F. Dutton, Mr. B. E. Bell coming second with Britannia, and the Thatcham Fruit and Flower Farm third with Beacon. There was only one vase of a crimson variety, and this was Mr. Engelmann's Carola, a fine form. Mr. Bell was first for any other self with Rose Doré, Mr. Burnett coming second with Mikado, and Mr. Engelmann third, also with Mikado.

For one vase of thirty-six flowers, one or more varieties, arranged with any foliage in a decorative manner, Mr. W. E. Wallace scored with a beautiful vase of May Day; Mr. B. E. Bell second with mixed varieties; and Thatcham Fruit and Flower Farm, Newbury, third. A first prize was awarded to Mr. Engelmann for a vase of a fancy variety—Harlequin; and he was awarded a second for a dozen flowers of a registered variety not in commerce, and here he showed a yellow variety.

In this section Mr. Bell's vase of Mrs. C. W. Ward won the silver-gilt medal as the best vase in the division.

AMATEURS.

In the amateur division there was only one entry of a collection of cut carnations, set up on a space 6ft. by 3ft., and this was from Mr. F. C. Stannett, gardener to Mr. F. May, Houndswood, Radlett, who had a fair display of blooms arranged with ferns.

Mr. A. E. Usher, gardener to Sir Randolf Baker, Bart., Ranston, Blandford, Dorset, led for a vase of Messrs. Low's novelties, Royal Purple and Roseate Dawn being his best blooms; Mr. Weston was placed second for Mr. Burnett's novelties, showing good blooms of Marmion. Mr. Usher scored for a dozen blooms in six varieties, and was followed in order by Mr. Warton, gardener to Lord Gerard, Eastwell Park, Kent, and Mr. J. Vert, gardener to Lord Howard de Walden, Audley End, Saffron Walden. In the classes for six flowers in one vase, there was a moderate competition. For a blush variety Mr. A. E. Usher scored with Mrs. Chas. Knopf, in very fine form.

For a light pink, Mr. Usher led with May Day, Mr. Warton coming second with Mrs. H. Burnett, and Mr. Vert third. In the rose-pink class Mr. A. E. Usher led with Rose Pink Enchantress; Mr. Weston second; and Mr. J. Vert third, also with the same variety. In the Lawson class Mr. Usher was again to the front, showing Lawson Enchantress; Mr. J. G. Weston second with Hannah Hobart; and Mr. Vert third.

In the white class Mr. Usher was first with Perfection; Mr. Weston second, and Mr. Vert third. The best scarlet variety was Robert Craig, superbly shown by Mr. Usher; Mr. Vert second with Britannia; and Mr. Weston third with the latter variety. Mr. Weston, Mr. Usher, and Mr. Vert led in the crimson class, the first two showing Carola in fine form. Mr. Weston scored for Mikado, with Mr. Usher second. Mr. Johnson was to the fore for a fancy variety with the popular Marmion; Mr. Usher second with Imperial; and Mr. Weston third with Marmion.

SMALL GROWERS.

In the division open to those who grow their flowers unaided, or have a gardener only part of the time, there was a fair number of entries, and here the leading prize winners were Mr. G. H. Lawrence, Stratton, Glastonbury; Mrs. Kenyon Fuller, Sonning; Mr. T. H. Plowright, Trinity Place, Windsor; and Mr. P. N. Patterson, South Drive, St. Annes-on-Sea; Enchantress, Beacon, and Royal Purple were the best flowers.

DECORATIVE EXHIBITS.

Three competitors entered in the amateur competition for a dinner-table decoration in carnations, and here Mrs. A. D. Ruff, Sharnbrook, Beds, scored with Rose Pink Enchantress nicely disposed; Miss Muscutt, Church Street, Wolverton, second; and Mrs. Maslin, Addlestone, third. In the open class for a table decoration, Mrs. A. D. Ruff was again first, and this time she used Britannia with asparagus fronds and leaves of Caladium argyrites; Mr. Bealing, a good second, with a very pretty table of Mrs. Burnett, that might well have been placed first; and Messrs. Clark and Cook, Castlethorpe, Bucks, third, with a rather heavy arrangement of Mrs. Burnett.

Mrs. K. F. Hammond, King's Road, Sloan Square, S.W., was the only exhibitor of a basket of carnations, and was awarded first prize for a bold design of White Perfection and Marmion; a few flowers of the latter where the bow of ribbon was placed would have been an improvement. Mrs. Hammond had the best three ladies' sprays, and also the best three gents' button-hole bouquets; Mr. F. G. Bealing, Bassett, Southampton, second in the former class, and Mr. G. Johnson, gardener to Lord Burnham, Hall Barn, second in the latter class. Mrs. Hammond also had the best bouquet of carnations.

NON-COMPETITIVE.

Messrs. Cutbush and Son, Highgate, contributed a rather large group of carnations, the flowers being arranged in vases of varying heights so as to present an effective group. The leading varieties were Enchantress, Mrs. W. Ward, Beacon, O. P. Bassett, Lady Coventry, Marmion, Winsor, Rose Doré, Edna, and the curious purplish maroon Lady N. Brassey. Mr. C. F. Waters set up a somewhat small exhibit, from Balcombe, Sussex, and the variety most in evidence was the salmon-red Edith Waters, about a dozen vases representing this variety.

A very large exhibitor was Mr. C. Engelmann, Saffron Walden, but he rather crowded many of his blooms, setting his smaller vases too closely together. Of course, Carola was largely shown, and other leading varieties shown in some quantity were Mikado, Mrs. H. Burnett, Enchantress, Britannia, Rose Pink Enchantress, and Governor Duveen. Mr. H. Burnett, Guernsey, put up a large and beautiful exhibit of good flowers, his best varieties being R. F. Felton, Marmion, Rose Pink Enchantress, Fortuna, Mikado, and Mrs. H. Burnett.

In the big winter garden Messrs. Stuart Low and Co., Enfield, had a very large contribution, one-half consisting of Boronia megastigma, B. heterophylla, Callistemon saliginis, schizanthus, gerberas, acacias in variety, and hydrangeas. The other half was devoted to carnations arranged in bowls and bamboo stands, with fern fronds. The short-stemmed flowers in bowls were not particularly effective. Mikado, Lady Alington, Marmion, Rose Pink Enchantress, Beacon, Rose Doré, May Day and Britannia, Winsor and Royal Purple were well represented. Mr. A. Smith, Enfield Highway, showed a very large and beautiful vase of his new and delightful flesh-pink variety named Empire Day. Some delightful blooms of the Lyon rose and gerberas were put up by Messrs. R. Felton and Sons, Hanover Square, W.

A large group, composed of flowering plants in pots, and some stands of cut flowers, was arranged by Mr. A. Grubb, gardener to C. Raphael, Esq., Porters Park, Shenley; Britannia, Rose Doré, Carola, and Enchantress, were well represented, and the plants shown were full of flowers and buds.

MEDALS.

Gold.—To Mr. H. Burnett, Guernsey; Mr. C. Engelmann, Saffron Walden; Messrs. Stuart Low and Co., Enfield.

Silver-gilt.—Messrs. W. Cutbush and Son, Highgate, N.; C. Raphael, Esq., Porters Park, Shenley.

Cultivating the Soil.—The quarters in which apples and pears are growing that were dug over early in the spring may now have the surface broken down by the hoe or other tool, according to the texture of the soil. Most soils may be made quite fine at this time of year if it is done immediately after a light shower or two. The hoe should be kept regularly at work amongst the apples, pears, and plums on the surface, keeping an inch or two of fine loose soil, which is a great aid in conserving the moisture. This will be found one of the great factors in the production of fine fruit.—J. Whittle, Cheveney Gardens.

Templetonia retusa. — When hard-wooded plants were popular this was far more often grown than it is now, though as a flowering plant in the greenhouse it is at this season both distinct and pretty. This Templetonia, which, by the way, is also known as Templetonia glauca, forms a rather upright-growing shrub, whose shoots are clothed with oblong-shaped leaves about an inch in length. The flowers, which are of a peculiar salmon-red hue, are somewhat like those of small examples of Erythrina crista-galli. The season of blooming extends over a fairly lengthy period. A compost made up of two parts of peat to one part of loam, and a liberal sprinkling of sand, suits this templetonia well.—W. T.

THE HOLLIES.

(Concluded from page 324.)

I. cornuta, the "Horned Holly," of China, is so called on account of its curiously-arranged spines. Five large spines are usually found on each leaf, one on each side near the base, and three at the apex, a central one and two side ones. The leaves are oblong and bright green, with revolute margins. It forms a medium-sized, shapely bush, and is an acquisition to any garden where curious and interesting plants are encouraged.

I. crenata. - - Though this Japanese species may grow to a height of 10 feet or so under cultivation, and has been recorded 20 feet high in its native country, it is usually met with as a neat, compact bush, 2 to 4 feet high. It has moderately stiff shoots, clothed with tiny deep green leaves with crenated margins. For an isolated specimen or for planting in groups in conspicuous positions, it is well adapted. Its fruits are black. There are several varieties which differ from the type in the colour or shape of the leaves. A conspicuous one has golden variegated foliage.

I. dipyrena is sometimes called the "Himalayan Holly." It is only sufficiently hardy to survive in the southern and western counties, but it there grows into a large bush 15 feet or more high. The evergreen leaves are dull in appearance, having none of the gloss which is characteristic of I. aquifolium. The fruits are large and oval. The variety known in gardens as I. a. elliptica is correctly I. dipyrena elliptica.

I. integra is one of the so-called "Birdlime trees" of Japan. The species is found in both China and Japan, and is sometimes spoken of as Othera japonica. Its dark green leaves have usually entire margins, though occasionally a slight tendency to teeth are noticed. It is a distinct and ornamental species.

I. latifolia may be grown successfully in the southern counties, though it would not be advisable to plant it in the north. A native of Japan, it has been stated to be one of the handsomest broad-leaved trees of the country, and certainly when at its best in England it is very ornamental. The leaves may be anything between 4 and 8 inches long and between 2 and 4 inches wide. The margins of some forms are but slightly toothed, whilst those of others are spiny. The red fruits are smaller than those of the common holly, but are quite showy.

I. opaca is the holly of America, which occupies about a similar position in that country to I. aquifolium here. Its leaves are more opaque than those of the common species, and they are usually shorter. The fruits are red and very ornamental. It grows into a tree at least 30 feet high.

I. Pernyi is one of the new species of Ilex, several of which have appeared during the last few years. A native of Central China, it was introduced to this country by Messrs. Veitch, through the agency of their collector, Mr. E. H. Wilson. In China it has been met with at varying heights between 6 feet and 30 feet. Its evergreen leaves, though smaller, have a wonderful resemblance to those of I. cornuta. The plant is of good constitution, grows freely, and is likely to become exceedingly popular in gardens.

W. DALLIMORE.

HOW TO GROW SWEET PEAS.—"SWEET PEAS AND THEIR CULTIVATION," by C. H. Curtis (Secretary of the National Sweet Pea Society), is a complete guide to the successful culture of sweet peas for home or exhibition. Price 1s. net, by post 1s. 2d., or bound in cloth 1s. 6d., by post 1s. 8d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

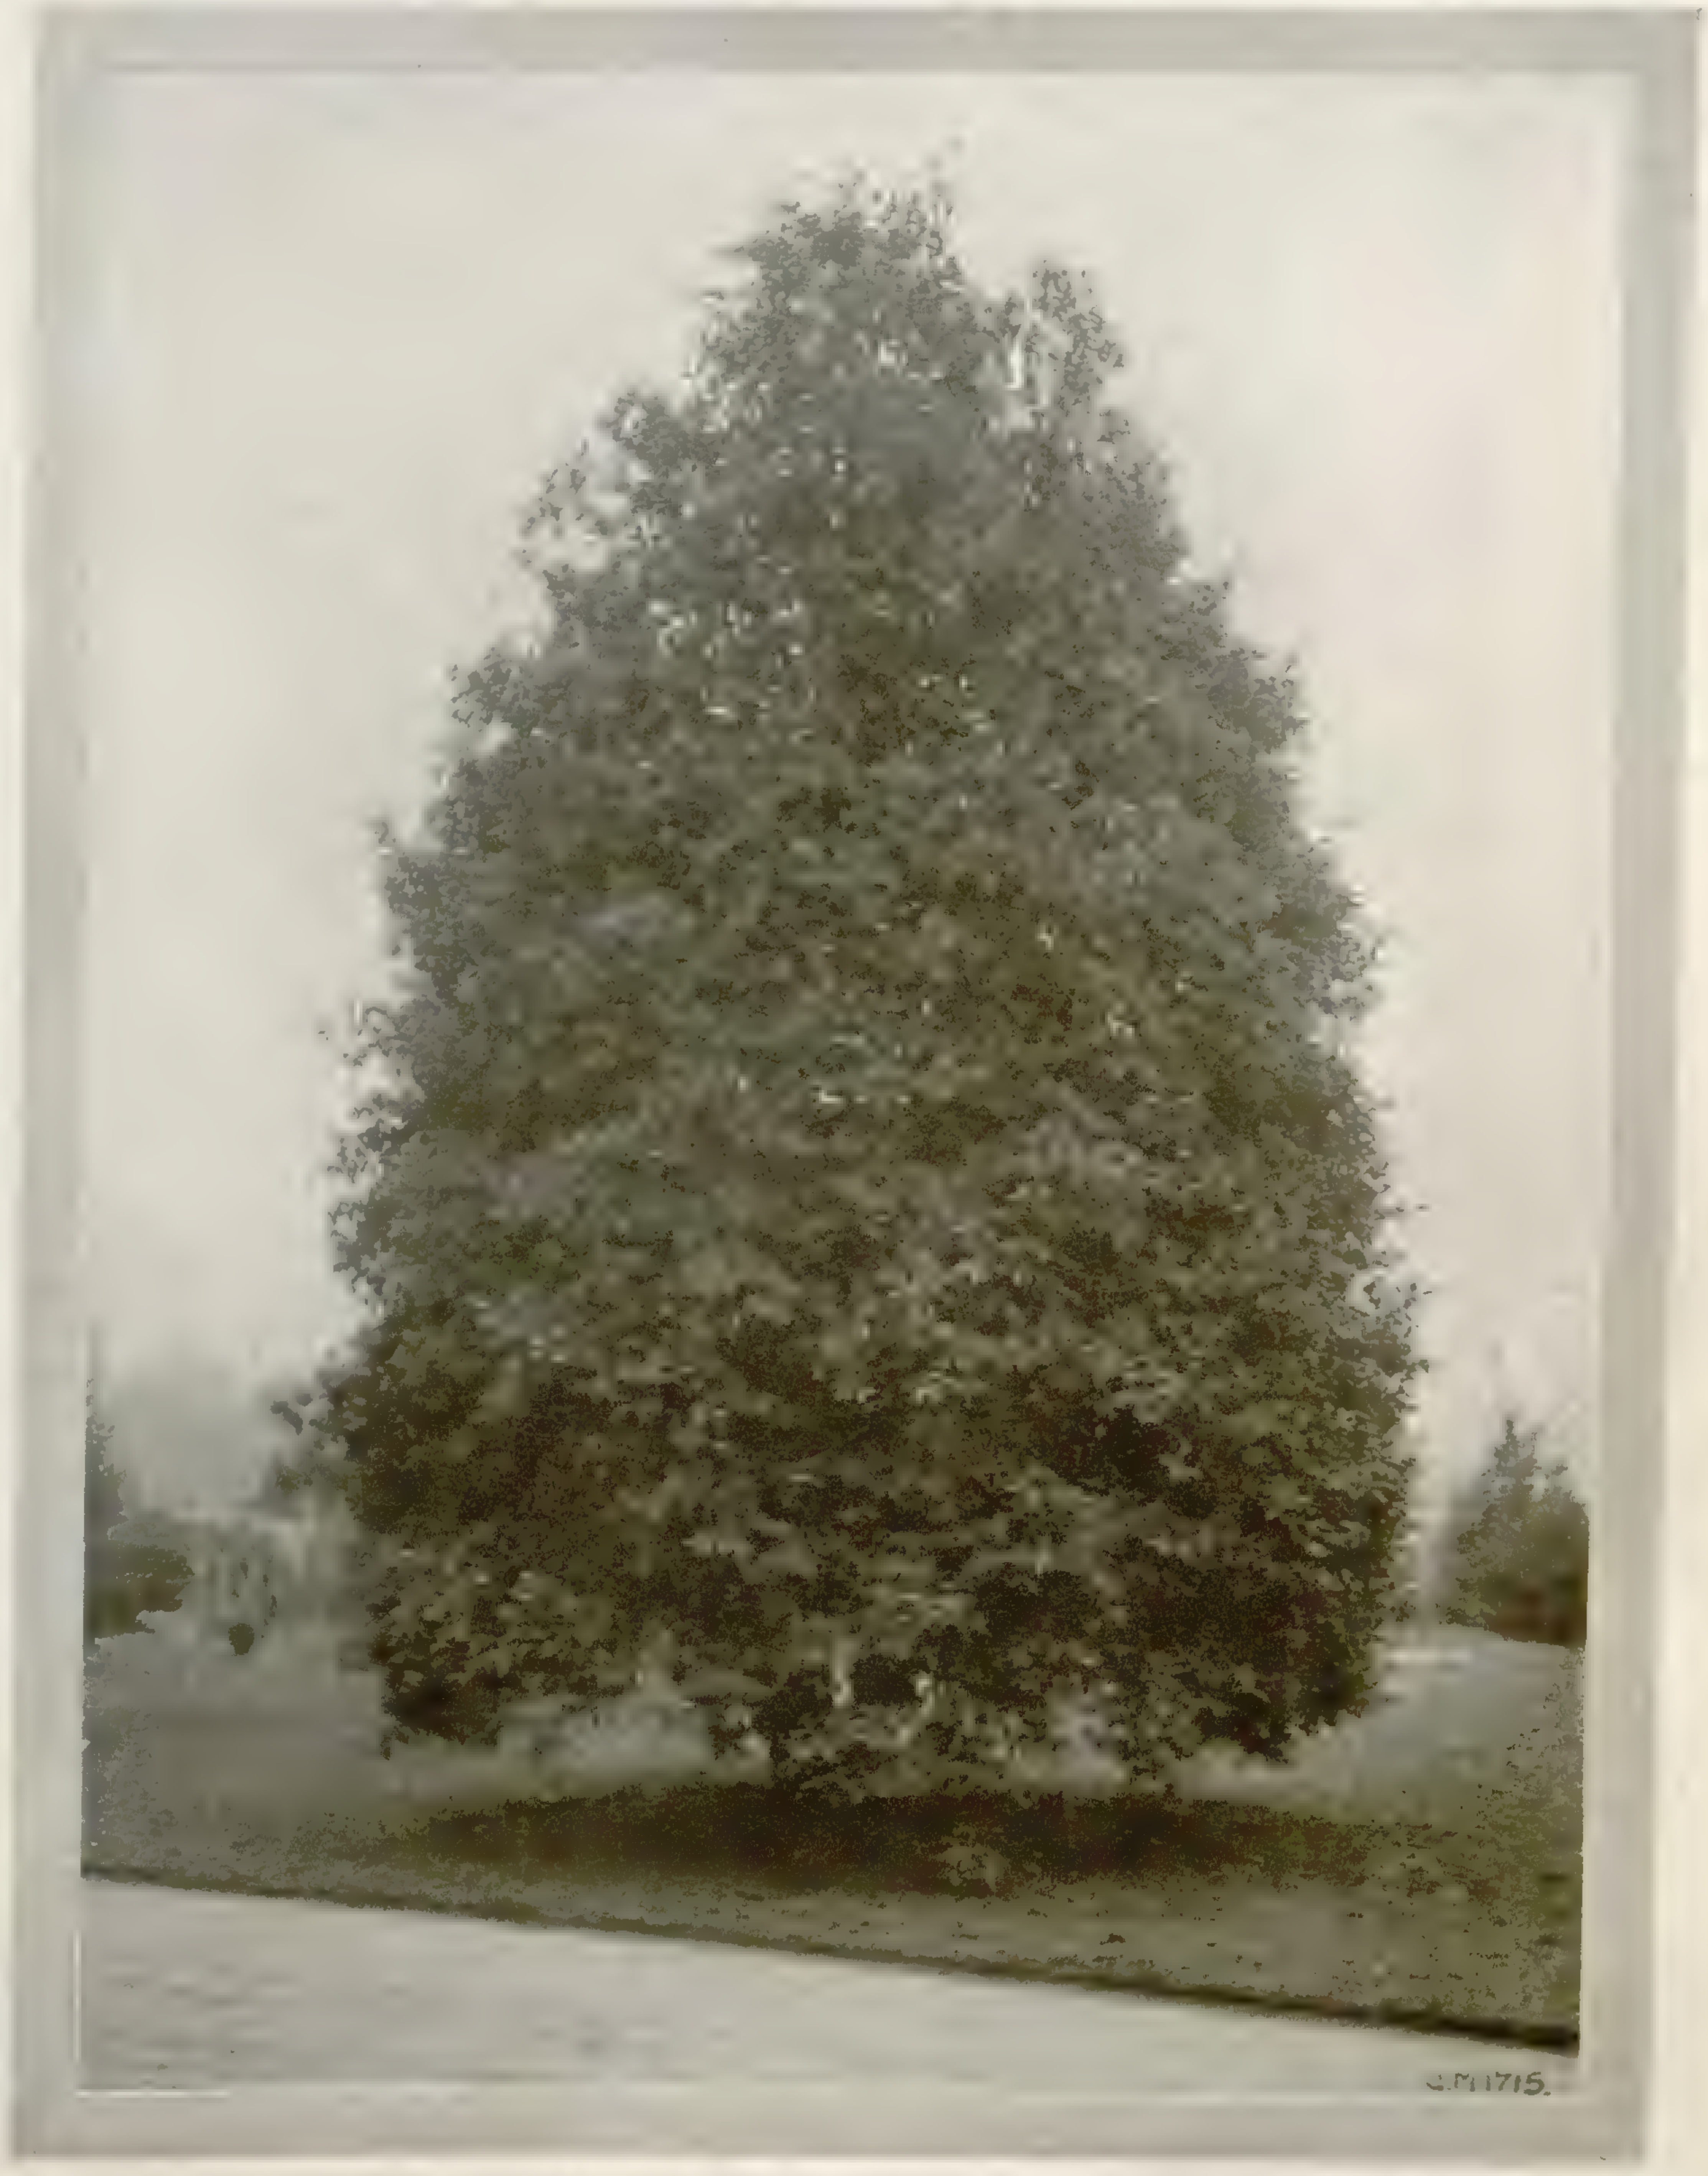
OUT-OF-DOOR PEACH CULTURE.

The brief note by "E.M.," page 286, on the successful cultivation of peaches on the open walls by Mr. T. Stevenson, at Woburn Place, recalls to my mind two cases of successful culture in Lancashire, three in Warwickshire, and several in Hampshire. Of course, there are scores of others in the country, but these have come under my notice, particularly as I have had to do with them, more or less, and they were instances far apart as regards situation. In Lancashire trees were grown under glass and trained on open walls, and at both establishments the positions of the glass structures and the uncovered walls were the same. In the north of the county all round success was achieved. In the south the trees on the open walls were a great success, but only a partial one under glass. The gardener, a very experienced cultivator, did everything possible to ensure full crops under glass, but never succeeded. In the open air he had excellent crops year after year.

At both establishments ample space was allowed for the young shoots to grow and mature in, and a broad band of tiffany was always lowered when rain and hail showers came, also when very cold winds prevailed. Every night, until the young fruits were set, the sheet of tiffany was lowered without fail. The chief difficulty under glass was the non-setting of the flowers.

In Warwickshire the long walls of peach and nectarine trees were similarly treated, and proved successful. Equal satisfaction was the result of timely coverings and thin training of the young shoots in Hampshire. In one establishment I had 210 feet of wall covered with glass, facing south-south-east, and near the top ventilators the leaves suffered from blister a little when east winds prevailed. On 200 feet run of wall having a similar aspect I at first only covered the top portion of the trees when in bloom, and, as a result, that part of each tree was free from blister, while the lower, or exposed part suffered. Herring nets doubled let down to the ground afterwards had the desired effect. On a long wall facing due west, in the same garden, the peach and nectarine trees were not much blistered, and these trees were protected more scantily than the others. I know of instances where neglect as regards the thin tying-in of the young shoots and covering the trees at the flowering stage has had one result four years out of five, i.e., failure.

GEO GARNER.



THE HIMALAYAN HOLLY (ILEX DIPYRENA).

The handsome specimen, herewith illustrated of this distinct narrow-leaved species, occupies a prominent position in the Kew collection.

EVESHAM IN APRIL.

It was one of those delightful springlike days we had during the Easter holidays that I journeyed over the Cotswold Hills and down into the fertile Vale of Evesham. What a contrast to be sure! The rolling scenery of the Cotswolds, miles of stone walls, great expanses of arable land, straight, monotonous roads, few trees, farmsteads dotted here and there at long intervals, and ever and again a grey stone church nestling, as it were, with a cluster of houses round it in one of those sheltered nooks which add a distinct charm of their own to the Cotswold country. How different the Vale of Evesham! Long before one reached the town there was evidence of the development of its fruit and market gardening industry in small holdings, allotments, and big fields which once grew corn now planted up with fruit and vegetable crops. On the hills one looked for the population, in the Vale it was apparent; there was a well-to-do air about the villages through which one passed, building was going on, which is always a sign of commercial activity; men, women, and lads were at work on the land; and in the depth and character of the soil one observed that Nature has endowed the Vale with facilities which are withheld on the Cotswolds.

The whole district gave the impression of one great garden, and the panorama of blossom almost baffles description. Imagine if you can the waters of the Avon meandering through the Vale and the sloping hillsides one living sheet as far as the eye could see of pearly white plum blossom. That is Evesham in April, and if the district is not justified in calling itself the Garden of England, I know of no other that has a claim to the title. As I looked at that feast of blossom I thought of the thousands of pounds it represented—barring any accident in the shape of frost or other disaster and I remembered an article I had just read about the bee disease in the Isle of Wight, and the fear of fruit crops suffering in consequence; but surely if bees are absolutely essential for the fertilisation of fruit blossom Evesham would accommodate the occupants of every hive in the United Kingdom, and then not be supplied. A gentle breeze played through the trees, the like of which Evesham growers appreciate in April, contending that it helps materially in the dispersal of pollen and the setting of fruit.

One noticed that every plum tree had the remnant of last autumn's grease band round it, and this is a reminder that Evesham fruit growers are grease banders almost to a man, they believe in it, and by co-operation in doing it have warded off many a plague of caterpillars, but the general talk now is how very few winter moths were caught on the bands last season, and the deduction from this is that caterpillars should be less plentiful this time than usual. In and about amongst the plum plantations the eye rested on breaks of apples, and many of these were also white, not with blossom, of course, but lime, for round about Evesham lime-spraying has made great advances in the past few years, and in this operation many think that they have discovered the secret of spraying with definite results. It would be wrong to describe the Evesham gardener as being conservative, indeed, he is very progressive and up-to-date. It is true that many strangers have flocked to the district, but a large percentage of the growers are natives. They or their fathers discovered the secret of this magic soil and situation years ago, and, aided by the security of tenure offered by the well-known Evesham system, have grown into prosperous citizens, who are ready to spend a pound if they can see a prospect of getting thirty shillings back for it.

As you wander through the broad, quaint streets of Evesham you see shop fronts set out with up-to-date spraying tackle and insecticides, and here you see a difference between the Evesham gardener and his neighbour, the West-Country farmer, who grows apples in his more or less antiquated orchard. The latter, with here and there an exception, scoffs at spraying as being a new-fangled idea of theorists, and accepts the periodical attacks of blight which ruin his crops as being something that is inevitable and unavoidable. The Evesham man takes another view entirely, he is a born fighter, fruit is a big egg in his basket, he must save it, if possible, so the sprayer has established itself amongst him and his class, and every year spraying becomes more and more a part of the cultural routine. The farmer with his grass orchard might do well to take a lesson, and he may take it for granted that his Evesham friend does not spend time and money on grease bands, sprayers, and insecticides just for mere amusement, for he is very much too wide awake for that.

It was not only the blossom on the trees which struck me on that bright April day, though the florescence of the Pershores, Victorias, and Prolifics made the greatest show, but here and there, underneath the trees, the heads of thousands of yellow daffodils and pearly white narcissi nodded in the breeze, and the air was redolent with the scent of wallflowers. The Evesham grower is a man of parts, everything is fish that comes to his net, and the customers who take his fruit and vegetables also want flowers which do not cost a great deal to grow. At a distance one only saw the plum trees and the blossom, but getting nearer one observed men and women bending over long beds of something green. They were radishes, and further on was the bright green of thousands of lettuces that had stood the winter, while along the road one passed dray after dray piled up with spring cabbages off to market. Cabbage is a great crop with Evesham gardeners, and it is a thorn in the side of outside growers that within that favoured circle spring cabbage is ready for cutting a week or two earlier than it is a few miles away, and that little time makes a considerable difference to the price.

"Grass" is a word that comes frequently into the vocabulary of Evesham folk, and it refers to one of their most paying crops, i.e. asparagus. The harvest of the "grass" has yet to come, but one saw the preparation, in the form of dozens of men forking down the crowns of the narrow beds or ridges in readiness for the appearance of the heads. In a general way we look upon asparagus as a somewhat aristocratic crop that is expensive to grow, but round about Evesham it is the mainstay of dozens of small holders, who, with their simple methods of cultivation, produce some of the finest asparagus that is seen in the market.

On the visit I am recording, I saw nothing of Evesham's French gardens, unless I can apply the term to hundreds of handlights covering early cauliflowers planted in triangles, from which they are removed in due course to afford similar protection to the young marrows. There seems to be always something selling at Evesham, and an everlasting interest in the state of the market. Just now it is a question every day about the cabbage being up or down, the next thing will be the state of the asparagus market, followed by the sale of the gooseberries, and, later, the plum trade, which is of stupendous importance, for at that season Evesham is the centre of gravitation for buyers from the length and breadth of the kingdom.

One thing that strikes you is the commercial activity of the place, and it all savours of gardening. The town is of historic interest, and was, of course, there first; but it seems to have grown up amongst the gardens, which, as it were, are next door to the shops, and every other man you meet has the brown soil adhering to his boots which stamps him as a gardener. Birmingham is not far distant, and on the day of my visit I met many representatives of its people who had come to see the blossom, and their pale cheeks and towny appearance presented a striking contrast to Evesham's sturdy sons of the soil.

I grant you that Evesham men work hard, but they present no slavish, downcast mien, which writers often associate with workers on the land. On the other hand, they are manly and independent, if somewhat rough and ready, practical to their finger-ends, and capable of looking after their own. As I turned my wheel homeward, leaving this fair scene behind me, until at length there were no more plum trees, cabbage fields, small holdings, and asparagus beds, I felt that not only had the day been profitably and agreeably spent, but that this country of ours can present to the tourist a no more beautiful picture than the Vale of Evesham in April.

H.

HYBRID RUGOSA ROSES.

Rugosas are such a hardy and accommodating class of roses, needing scarcely any attention when once planted, and making one of the best hedges or fences of roses, that they really should be more grown where there is space available. The old pink and white singles are well known, and so is the seedling from the last-named, the beautiful Blanc Double de Coubert, one of the purest white roses we have, with not a suspicion of pink about the blossoms.

There are several very good hybrids now, the chief of which is undoubtedly Conrad F. Meyer, a rose obtained by a double cross. This is a very vigorous grower, admirably adapted for pillars and large solitary bushes. The foliage, like all the rugosas, is seldom affected with diseases such as mildew and red rust, so that the plant always has a clean appearance. Conrad F. Meyer is also one of the sweetest scented roses, very large, exquisitely formed when young, and a clear silvery-rose in colour. Nova Zembla is a very pale blush-white sport from this, and differs only in colour. Rose a parfum de l'Hay has some sap of General Jacqueminot among it, and much of its exquisite perfume. This is also a late bloomer, and purplish-crimson in colour. One of the best and most distinct is Atropurpurea, a single-flowered variety that has very taking deep maroon-coloured buds, opening into deep crimson and purple-crimson flowers that are greatly improved by the showy stamens. The flowers, as in the case of those of the original singles, are followed by showy hips of intensely deep crimson colour.

Madame Georges Bruant is one of the first roses to open its flowers with me, does not cease all through the summer, and is in bloom when frosts arrive. This is a cross with the old tea Sombreuil, and the flowers are white, a little more than semi-double, and very round in the bud stage.

MODERN GLASSHOUSES

as supplied by MESSENGER and CO., Ltd., are made of the best materials, and only capable and reliable workmen are employed in the erection thereof.

The following letter was recently received by us on the completion of a contract for a well-known Member of Parliament.

February, 1911.

"I should not be doing my duty to your workmen if I did not at once tell you, on the completion of your work, how pleased I have been with each and all of them.

"They have been most obliging throughout the whole job, and have endeavoured to do everything in an efficient and thoroughly workmanlike manner, and I must congratulate you upon having such capable employees."

Barr's Lawn Phytobroma
The best Manure for all Lawns.

The most economical of all artificial manures, 2 oz. to the square yard only being required.
Per cwt., **20/**; ½-cwt., **12/6**; 28lb., **7/6**; 14lb., **4/6**; 7lb., **2/6**; sample tins, **1/-**.
Prepaid Orders for 28lbs. and upwards, carriage paid.
Circular with full particulars, on Application.

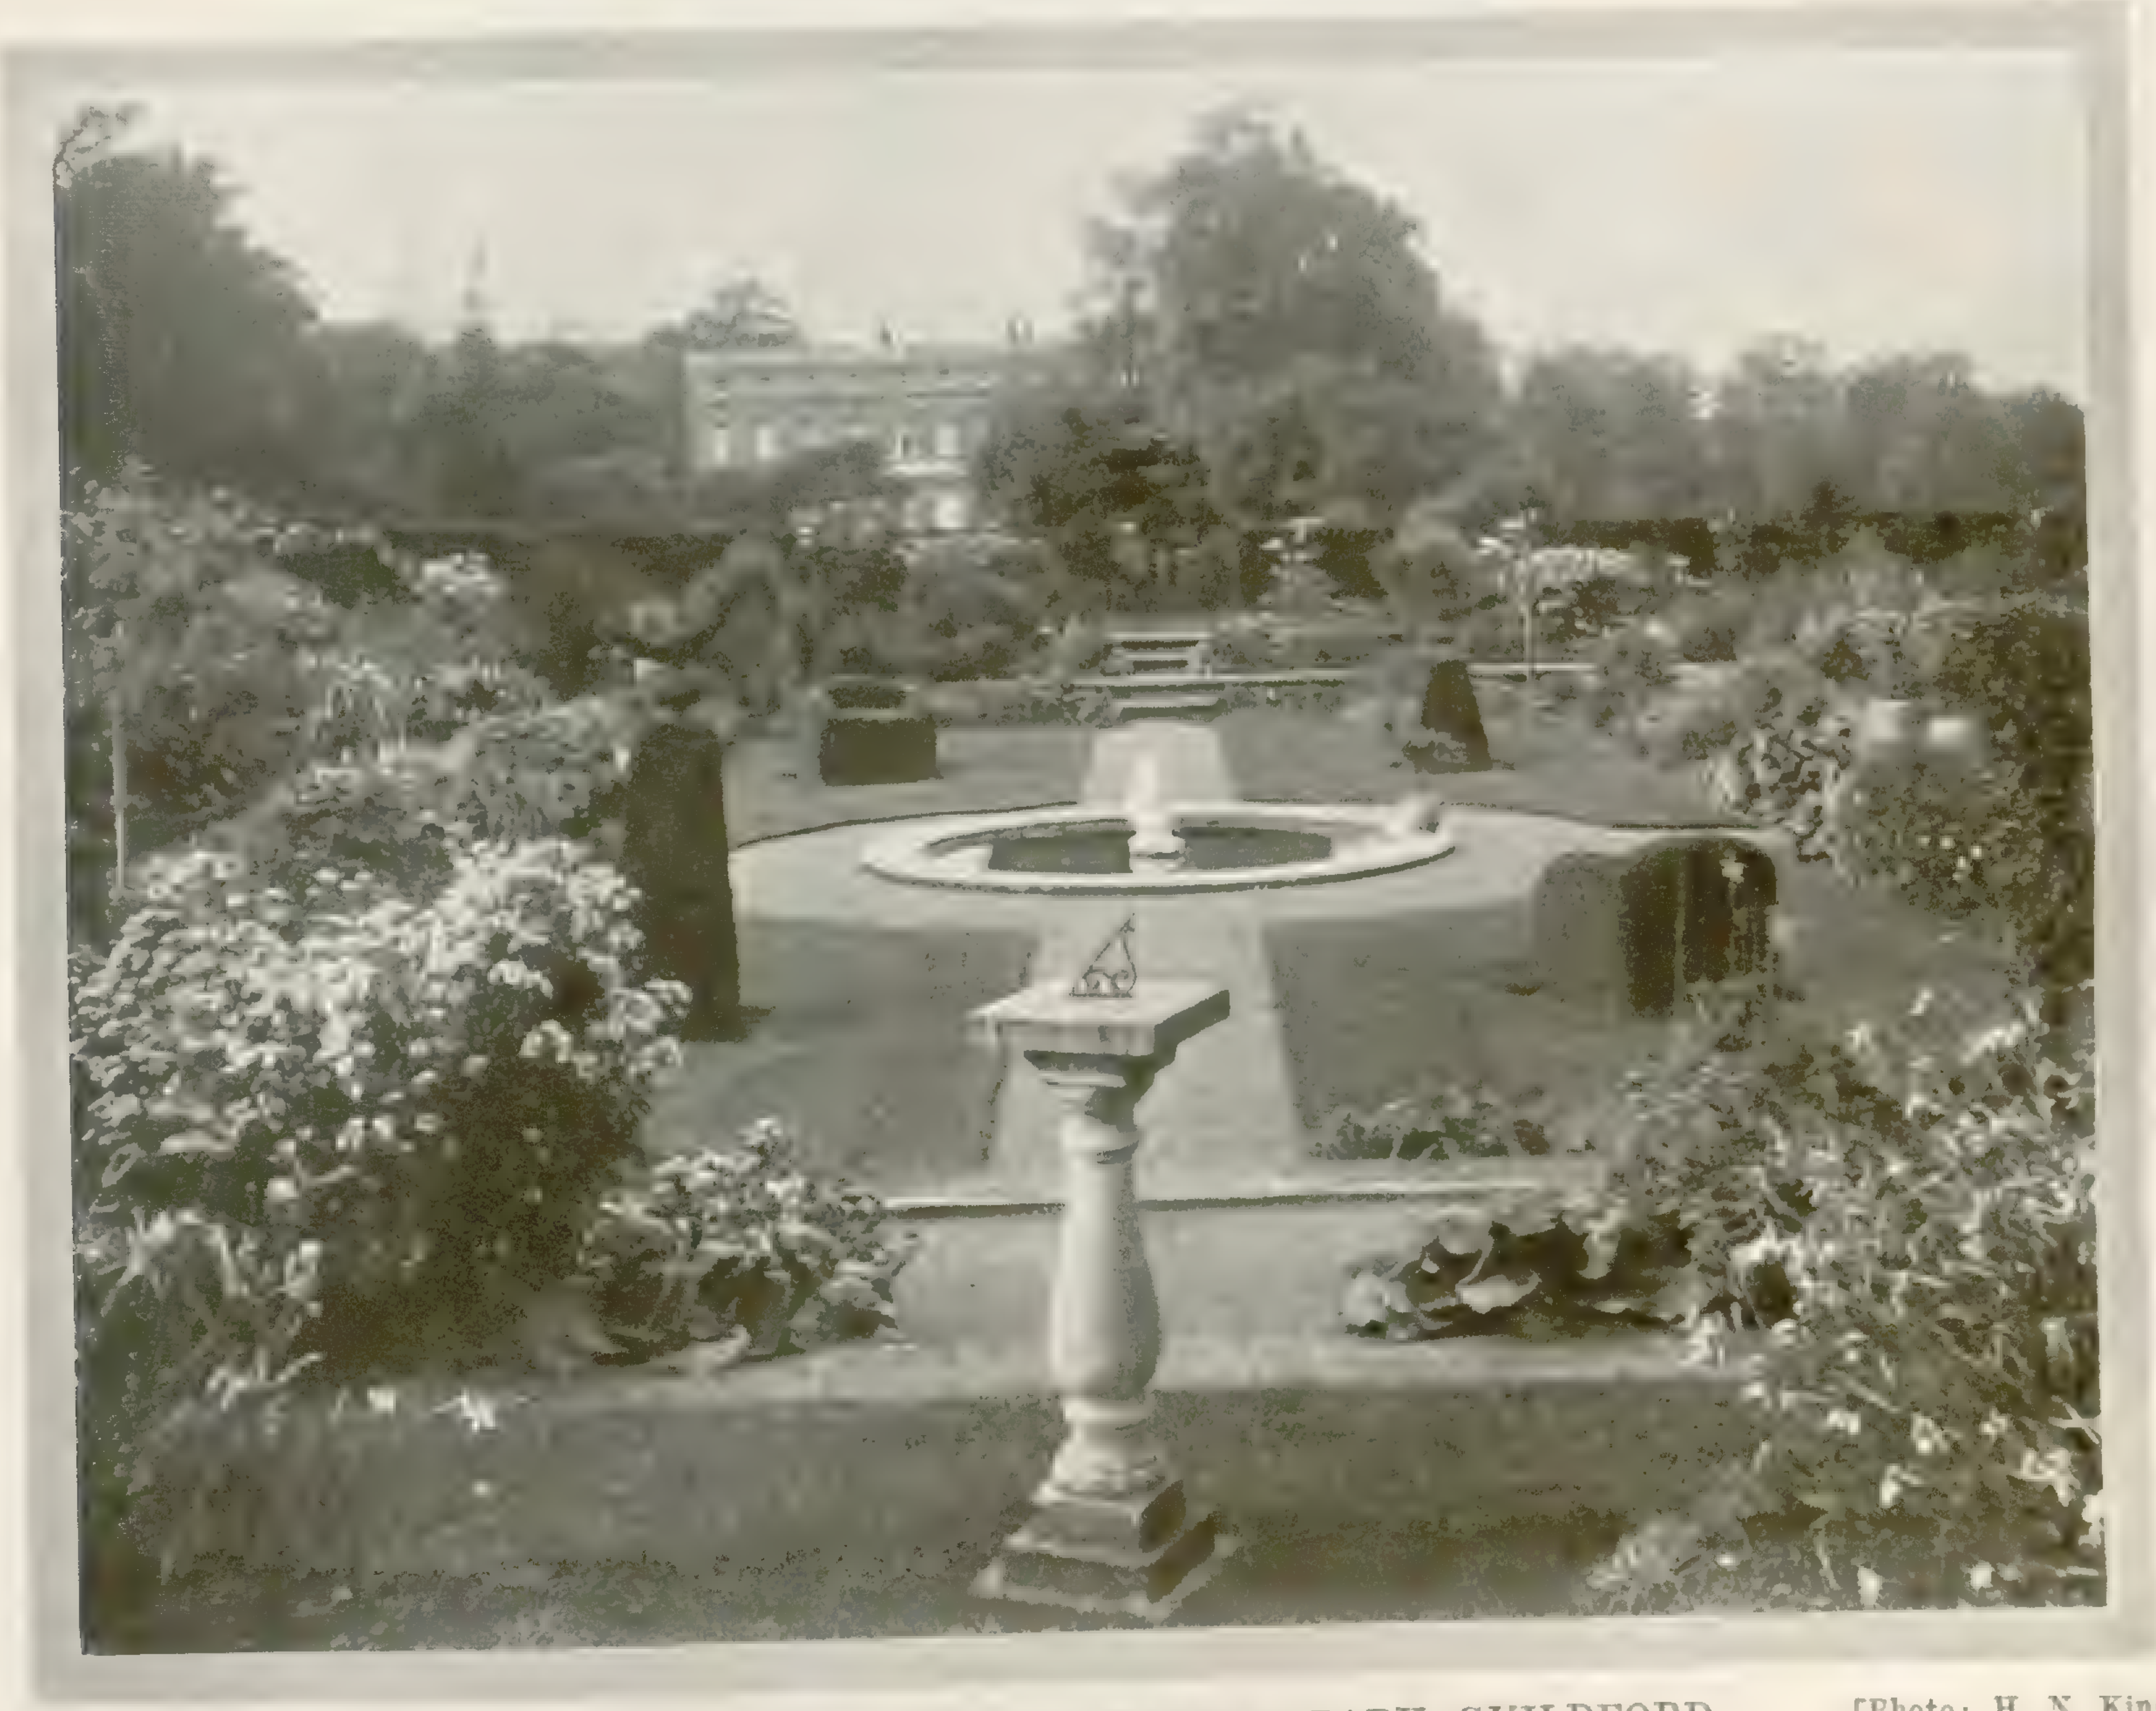
is absolutely "PERFECT."
4 Tins of Powder or 4 Gallons of Liquid to make 100 Gallons.
6/6 Carriage Paid.
MARK SMITH, Ld. *Louth, Lincolnshire*

CLANDON PARK.

Anyone who visits many gardens quickly learns to grasp the main features of an establishment, and is pleased, or otherwise, accordingly as each garden reveals some glad surprises or conforms to some very general or commonplace plan. In most of the larger gardens in the county of Surrey, and they are many, there is little opportunity for owner or gardener to reduce the place to a common idea, because of the great variation of levels, and the consequent charm of hill and vale, placid lake and purling stream, woodland, meadow, and heath.

Round about Guildford lies a large area of beautiful country, and to the north-east of the old county town is Clandon Park, with its old-time red brick mansion, built in 1731, and set amid fine groups of trees, chiefly oak and elm. Clandon Park, the residence of the Earl and Countess of Onslow, possesses many attractions for the horticulturist, because the noble owners have taken an especially keen interest in the gardens during the last fifteen years, and they have been ably seconded in all their efforts by Mr. H. Blake, their head gardener. The gardens are not arranged to produce a specially brilliant effect at any particular season of the year, consequently from the time the great breadths of crocuses blossom in early spring, until the frost brings down the bright-hued leaves of elm, oak, and Japanese maple, there is a series of beautiful displays. Just outside the garden proper, and where the park slopes up to fence and wall, very many thousands of daffodils follow after the crocuses, and the huge informal colonies of fine varieties also follow each other in quick succession, until the latest of the poet's narcissi conclude this particular display.

Clandon Park has its pergola, with pillars of masonry along one side, and wood supports on the other; it is a copy of a pergola seen by Lord Onslow near Rome. This pergola connects the garden close to the mansion with a sunken garden. The latter is a very interesting feature, for although the plan of the garden and its beds and borders is strictly formal, and the whole is enclosed in a trimly-clipped yew hedge, the beds and borders are not planted in formal manner. A little pool and fountain occupy the centre, and there are quaintly clipped yew trees in each of the four little lawns. Herbaceous plants fill the beds and borders, and such things as eremuri, liliums, Michaelmas daisies, and anemones are a great success. The pergola, furnished almost wholly with roses and clematis, is remarkable also for the manner in which liliums, chiefly L. auratum, succeed in the narrow borders on either side. Lilies and roses form a delightful combination.



THE SUNKEN GARDEN AT CLANDON PARK, GUILDFORD. [Photo: H. N. King.

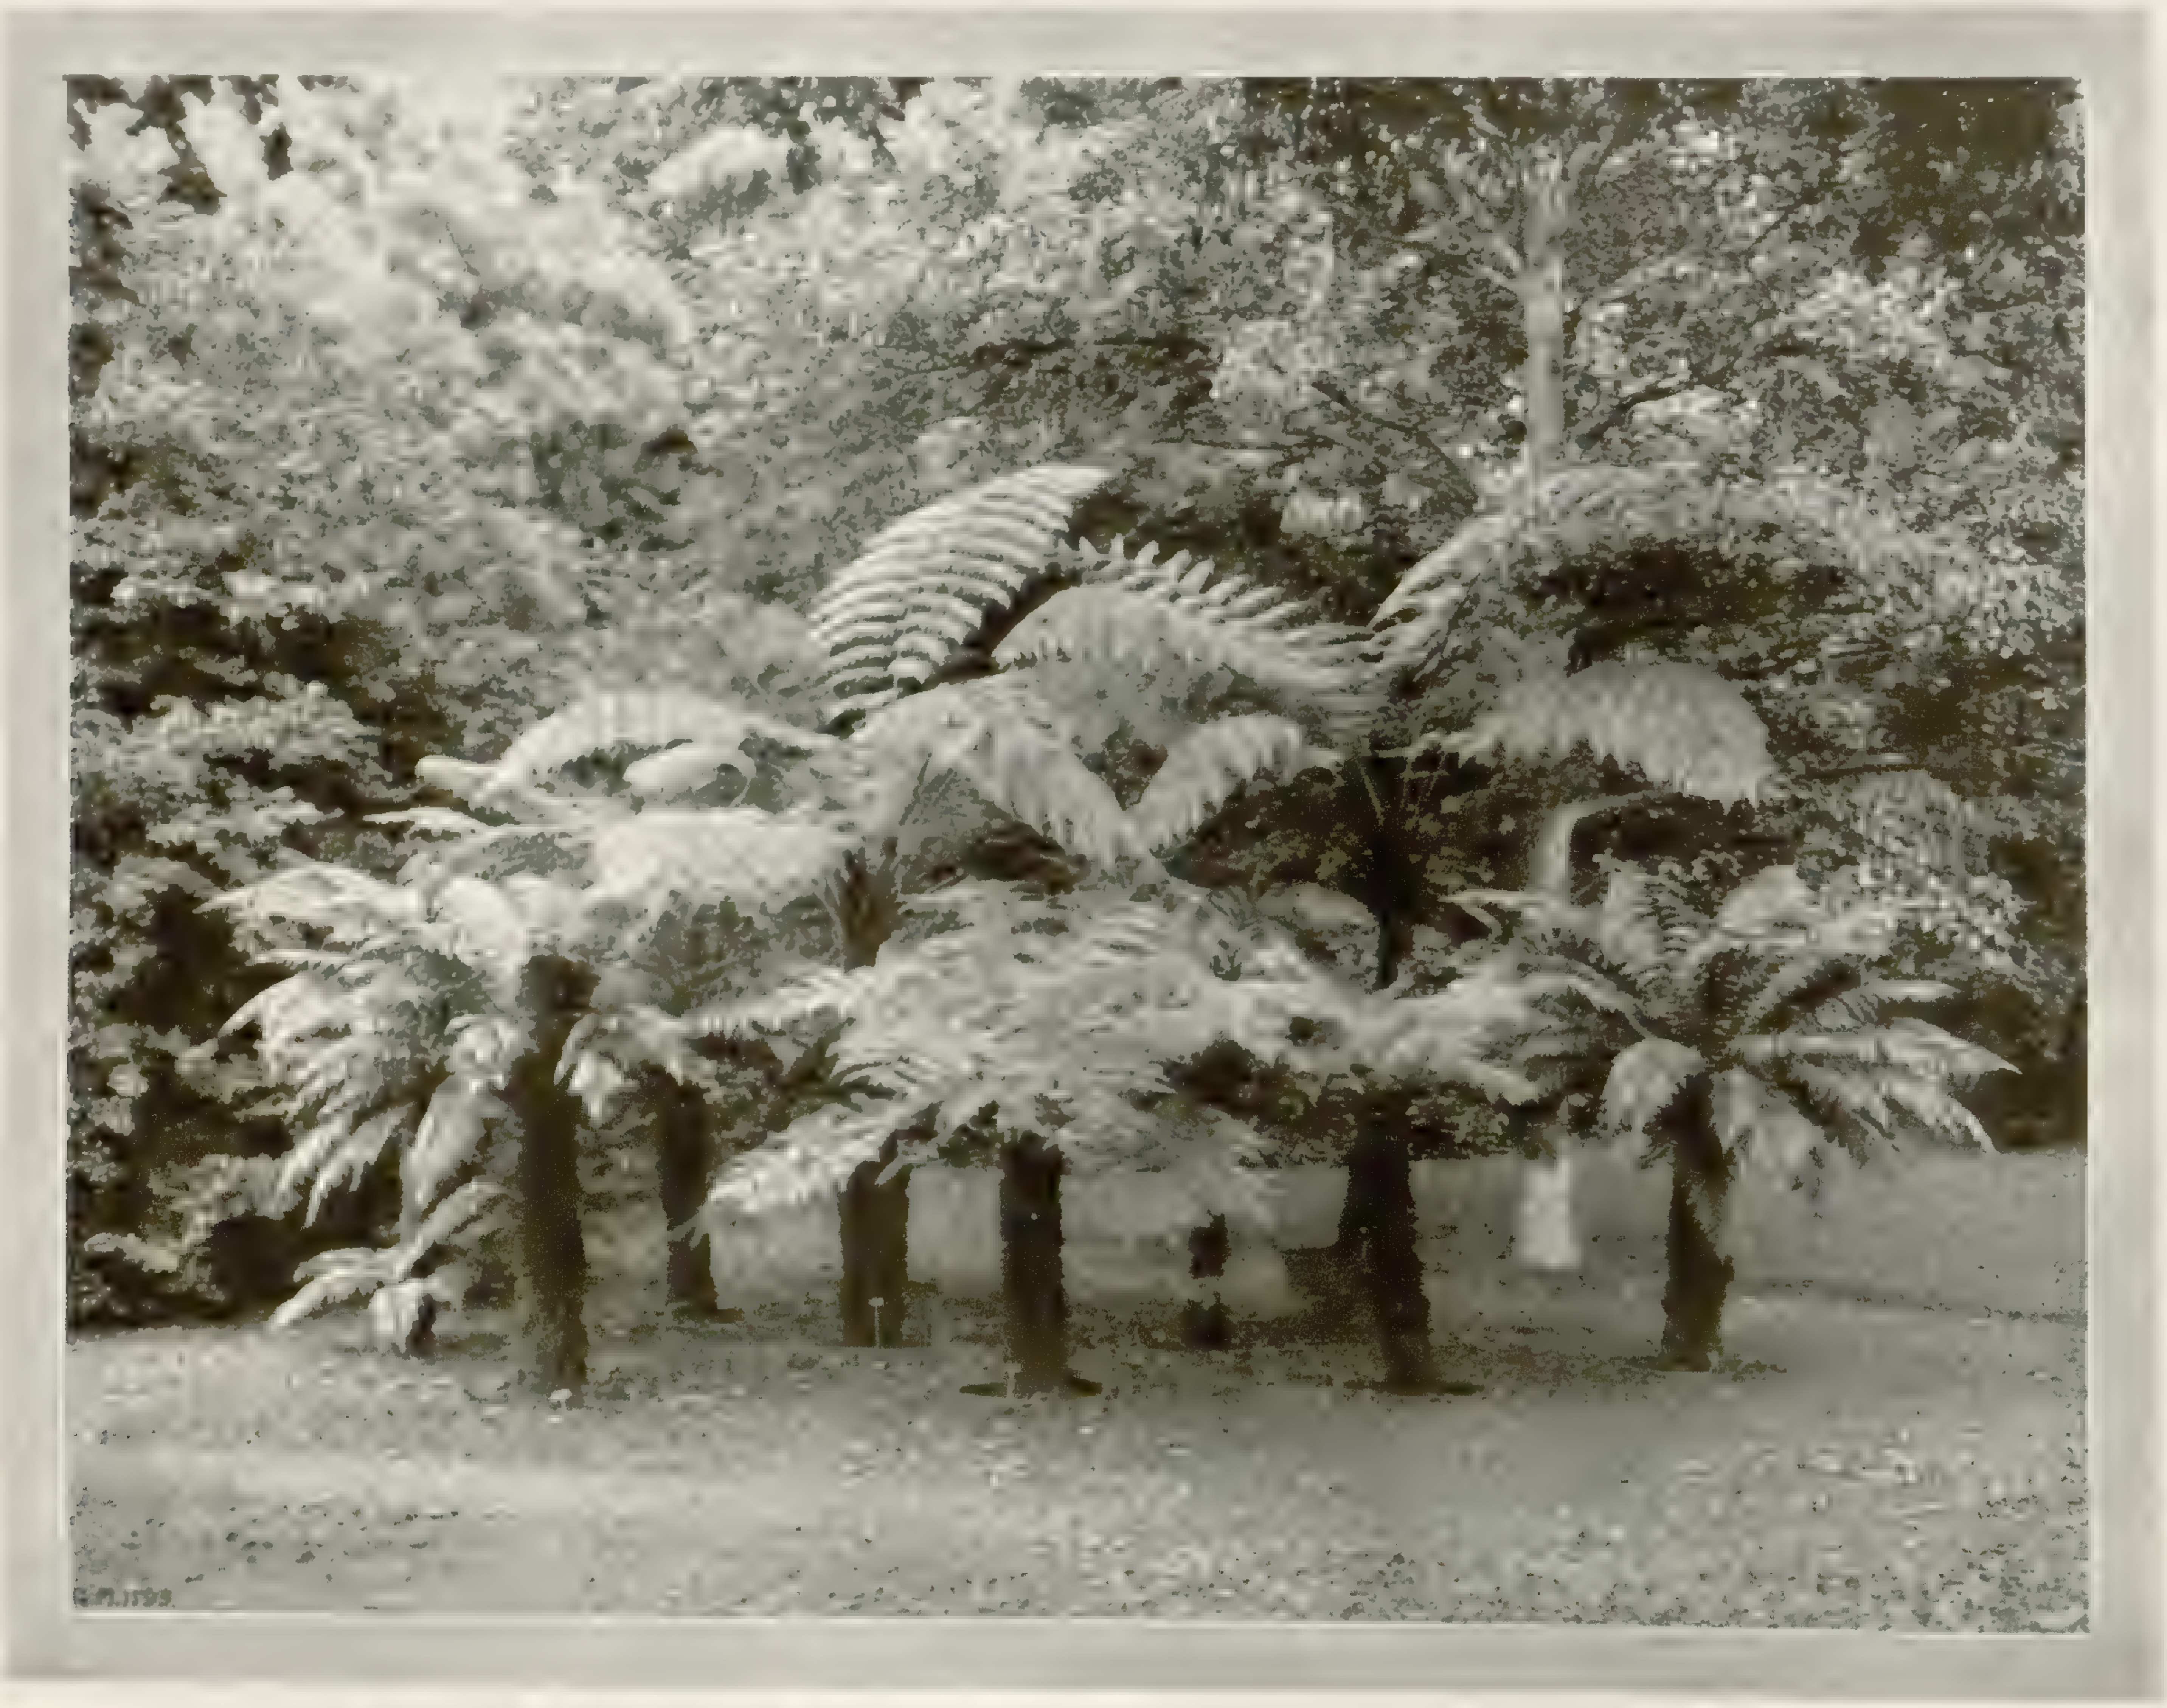
There is a little flower garden on the east side of the mansion, and practically every bed has been cut out of solid chalk and filled in with good soil. Before the garden is reached a particularly attractive feature is noticed, and it might well be called a garden of Japanese maples. These elegant and beautiful shrubs are an unqualified success at Clandon Park, growing in a wide and long curved border, sheltered by old elms and set in full sunshine, hundreds of plants thrive, and year after year produce a scene that the flowers cannot excel for brilliance or colouring. During this last season Mr. Blake has lifted every plant, remade the border, and replanted the maples, giving them additional and needful space. The dissectum and red-leaved varieties are well represented in this splendid group.

Conifers do well on the rising ground eastward, and there is a stately avenue of Cupressus Lawsonianus and another of erect Irish yews. Very fine is the Cranley Avenue, that extends from the front of the mansion to the Guildford Road. It is a double avenue, the inner lines composed of copper beeches backed by lines of common beech. The trees are now of good size and handsome shape.

Water is plentiful at Clandon Park as springs abound, therefore it has been used, or taken advantage of to greatly improve the interest and attractions of the garden. One fairly large piece of water is known as "The Canal." Here the water, rising from an unfailing spring, is dammed back just as it was in the old days, when it was necessary to obtain a good head of water to drive the mill lower down. Steep banks rise all round, and, at the entrance to this part of the garden bamboos thrive wonderfully well, being represented by splendid masses that rise to upwards of a dozen feet. Here they have ample shelter from winds, and their roots are practically always in moisture.

But the great feature of Clandon Park gardens is the irises, and on the banks of the Canal these are planted in their thousands. Down near the water edge, and below the water line in summer, are the beautiful Japanese varieties of Iris lævigata (I. Kæmpferi). Higher up, where a path is terraced out of the bank, Iris stylosa flowers almost all the winter, and has the benefit of almost every ray of sunshine the year round. On either side of the path are big colonies of German or flag irises, this big group being represented by numerous fine varieties of each of the several sections. Spanish and English irises find here a congenial home, and the early-flowering varieties of the I. pumila group are also planted freely. Most of the hardy species obtainable in quantity are represented, but the foregoing, with varieties of I. sibirica, form the bulk of a display that must be the finest of its kind in the county, for irises extend for about 250 yards along the banks of the Canal.

There are, however, other subjects here besides irises, and flowering shrubs, notably rhododendrons, spiræas, and sweet briar, form a background for the lowlier plants, while dogwoods and willows and white-stemmed brambles lend colour to the scene during winter by means of their coloured bark. Here and there also are goodly clumps of hemerocallis, herbaceous spiræas, and alstroemerias, which stand out conspicuously.



GROUP OF TREE FERNS AT CLANDON PARK, GUILDFORD. [Photo: H. N. King.

Another charming feature is the Primula Dell. Here, under the trees, with little streams of water running round and among the mounds, great colonies of hardy primulas have been planted, and they thrive in a fashion that must be most gratifying to Mr. Blake, who has taken very great pains to make this dell an unique as well as a beautiful feature. In the early summer time he dams up the little serpentine stream until it floods the lower levels of the dell, and this creates an atmospheric as well as soil moisture, to which the primulas gaily respond, making big leaves and fine crowns against the floral harvest of another year. Three species of primula are here grown in their thousands, and these are P. cashmeriana, with its varieties denticulata and alba; P. japonica in many shades of colour; and the lovely P. rosea. P. Veitchi, P. Cockburniana, and P. pulverulenta are also included. Abundance of moisture, the shelter from wind and frost that thinly overhanging trees afford, and abundance of leaf-soil, appear to be the chief requirements of these primulas, and doubtless there are many gardens where a corner of a woodland could be turned into a delightful garden, just as the Primula Dell has at Clandon Park. Primroses, polyanthuses, forget-me-nots, and meconopsis, including the new M. integrifolia, are also skilfully managed in this dell.

Yet another very fine feature remains, and it is the water garden. This is further afield, and has developed in a curious way. Some years ago, on returning from the Governorship of New Zealand, Lord Onslow obtained a fine old Maori Council House, and this quaintly carved structure was erected near the far end of a piece of water. Presently the idea of converting the ground on either side of the water, up to the Council House, into a garden, was entertained, the work was begun, and gradually developed and extended. Irises abound, indeed Lord Onslow has a very great love and admiration for irises of all kinds, and they respond to the care bestowed upon them in no uncertain fashion. Iris sibirica, I. Snow Queen, I. gigantea, I. virginica, I. lævigata, I. germanica, I. albo-purpurea, I. florentina, and many others flourish all through this water garden. Water lilies deck the pool close to the Council House, and great masses of Crimson Rambler rose threaten to hide the thatch on the roof of the house, while Gunnera manicata at the water's edge becomes a huge mass of gigantic leafage each summer.

Large groups of roses, senecios, spiræas, Hydrangea paniculata, kniphofias, verbascums, and hemerocallis occupy positions a little away from the water.

Fragrant plants are grouped in a yew-enclosed garden some distance from the water garden; here are daphnes, roses, lavender, stocks, mignonette, carnations, musk, and sweetly-scented herbs, with Aloysia citriodora added in the summer. Near by, and outside the high walls of the kitchen and fruit gardens, roses are planted very largely in beds, with rambling varieties on pillars and chains, and on a trellis at one end, as well as on the wall itself. In the beds the stronger-growing roses are placed, and these are tied down instead of being pegged down; a stout wire frame is laid over the bed, and to this the sturdy growths are tied. This appears to be a method possessing many advantages over pegging, and one that might be generally adopted in the same or a modified form.

The glass houses at Clandon Park are not numerous. Excellent grapes and peaches are grown, and there is a good collection of palms and tree ferns; the latter are placed out of doors in the summer, and form a very interesting group, reminiscent of Lord Onslow's sojourn in New Zealand. The kitchen garden is of considerable extent, and the crops here, as well as the peaches on walls (trained to wires, not nailed), are ample evidence that Mr. Blake's skill is not confined to primulas, irises, daffodils, and Japanese maples, or the construction of dells and water gardens.

Charles H. Curtis.

Salads.—During the next few months liberal supplies of salad will be demanded, and, fortunately, it can be more easily supplied. Make larger sowings of lettuce, radish, mustard and cress, in warm positions on borders, and plants of lettuce from the frame yard will be hardened off ready for planting out.—C. F.

NOTES FROM KEW.

Himalayan Rhododendrons.
